Chapter 1
Measurement and Vectors

Conceptual Problems

1 • **[SSM]** Which of the following *is not* one of the base quantities in the SI system? (*a*) mass, (*b*) length, (*c*) energy, (*d*) time, (*e*) All of the above are base quantities.

Determine the Concept The base quantities in the SI system include mass, length, and time. Force is not a base quantity. $\boxed{(c)}$ is correct.

2 • In doing a calculation, you end up with m/s in the numerator and m/s^2 in the denominator. What are your final units? (*a*) m^2/s^3, (*b*) 1/s, (*c*) s^3/m^2, (*d*) s, (*e*) m/s.

Picture the Problem We can express and simplify the ratio of m/s to m/s^2 to determine the final units.

Express and simplify the ratio of m/s to m/s^2:

$$\frac{\frac{\text{m}}{\text{s}}}{\frac{\text{m}}{\text{s}^2}}=\frac{\text{m}\cdot\text{s}^2}{\text{m}\cdot\text{s}}=\text{s and }\boxed{(d)}\text{ is correct.}$$

3 • The prefix giga means (*a*) 10^3, (*b*) 10^6, (*c*) 10^9, (*d*) 10^{12}, (*e*) 10^{15}.

Determine the Concept Consulting Table 1-1 we note that the prefix giga means 10^9. $\boxed{(c)}$ is correct.

4 • The prefix mega means (*a*) 10^{-9}, (*b*) 10^{-6}, (*c*) 10^{-3}, (*d*) 10^6, (*e*) 10^9.

Determine the Concept Consulting Table 1-1 we note that the prefix mega means 10^6. $\boxed{(d)}$ is correct.

5 • **[SSM]** Show that there are 30.48 cm per foot. How many centimeters are there in one mile?

Picture the Problem We can use the facts that there are 2.540 centimeters in 1 inch and 12 inches in 1 foot to show that there are 30.48 cm per ft. We can then use the fact that there are 5280 feet in 1 mile to find the number of centimeters in one mile.

Multiply 2.540 cm/in by 12 in/ft to find the number of cm per ft:

$$\left(2.540\frac{\text{cm}}{\text{in}}\right)\left(12\frac{\text{in}}{\text{ft}}\right)=\boxed{30.48\,\text{cm/ft}}$$

Multiply 30.48 cm/ft by 5280 ft/mi to find the number of centimeters in one mile:

$$\left(30.48\frac{\text{cm}}{\text{ft}}\right)\left(5280\frac{\text{ft}}{\text{mi}}\right)=\boxed{1.609\times10^{5}\ \text{cm/mi}}$$

Remarks: Because there are exactly 2.54 cm in 1 in and exactly 12 inches in 1 ft, we are justified in reporting four significant figures in these results.

6 • The number 0.000 513 0 has ____ significant figures. (*a*) one, (*b*) three, (*c*) four, (*d*) seven, (*e*) eight.

Determine the Concept Counting from left to right and ignoring zeros to the left of the first nonzero digit, the last significant figure is the first digit that is in doubt. Applying this criterion, the three zeros after the decimal point are not significant figures, but the last zero is significant. Hence, there are four significant figures in this number. $\boxed{(c)}$ is correct.

7 • The number 23.0040 has ____ significant figures. (*a*) two, (*b*) three, (*c*) four, (*d*) five, (*e*) six.

Determine the Concept Counting from left to right, the last significant figure is the first digit that is in doubt. Applying this criterion, there are six significant figures in this number. $\boxed{(e)}$ is correct.

8 • Force has dimensions of mass times acceleration. Acceleration has dimensions of speed divided by time. Pressure is defined as force divided by area. What are the dimensions of pressure? Express pressure in terms of the SI base units kilogram, meter and second.

Determine the Concept We can use the definitions of force and pressure, together with the dimensions of mass, acceleration, and length, to find the dimensions of pressure. We can express pressure in terms of the SI base units by substituting the base units for mass, acceleration, and length in the definition of pressure.

Use the definition of pressure and the dimensions of force and area to obtain:

$$[P]=\frac{[F]}{[A]}=\frac{\frac{\mathrm{ML}}{\mathrm{T}^2}}{\mathrm{L}^2}=\boxed{\frac{\mathrm{M}}{\mathrm{LT}^2}}$$

Express pressure in terms of the SI base units to obtain:

$$\frac{\mathrm{N}}{\mathrm{m}^2}=\frac{\mathrm{kg}\cdot\frac{\mathrm{m}}{\mathrm{s}^2}}{\mathrm{m}^2}=\boxed{\frac{\mathrm{kg}}{\mathrm{m}\cdot\mathrm{s}^2}}$$

9 • True or false: Two quantities must have the same dimensions in order to be multiplied.

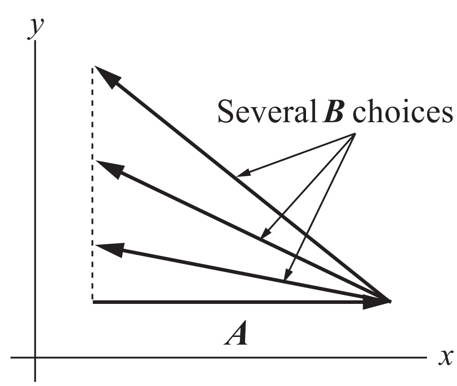
False. For example, the distance traveled by an object is the product of its speed (length/time) multiplied by its time of travel (time).

10 • A vector has a negative *x* component and a positive *y* component. Its angle measured counterclockwise from the positive *x* axis is (*a*) between zero and 90 degrees. (*b*) between 90 and 180 degrees. (*c*) More than 180 degrees.

Determine the Concept Because a vector with a negative *x*-component and a positive *y*-component is in the second quadrant, its angle is between 90 and 180 degrees. $\boxed{(b)\text{ is correct.}}$

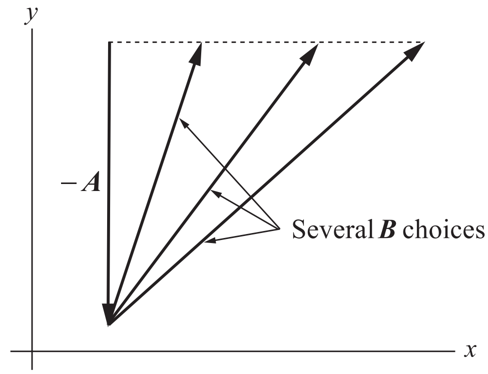
11 • **[SSM]** A vector $\vec{A}$ points in the +*x* direction. Show graphically at least three choices for a vector $\vec{B}$ such that $\vec{B}+\vec{A}$ points in the +*y* direction.

Determine the Concept The figure shows a vector $\vec{A}$ pointing in the positive *x* direction and three unlabeled possibilities for vector $\vec{B}$. Note that the choices for $\vec{B}$ start at the end of vector $\vec{A}$ rather than at its initial point. Note further that this configuration could be in any quadrant of the reference system shown.



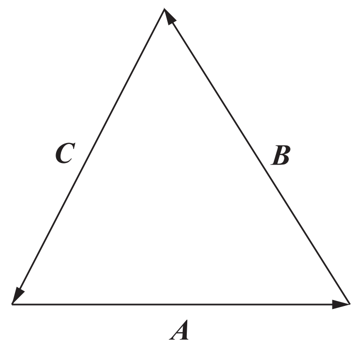
12 • A vector $\vec{A}$ points in the +*y* direction. Show graphically at least three choices for a vector $\vec{B}$ such that $\vec{B}-\vec{A}$ points in the + *x* direction.

Determine the Concept Let the $+x$ direction be to the right and the $+y$ direction be upward. The figure shows the vector $-\vec{A}$ pointing in the $-y$ direction and three unlabeled possibilities for vector $\vec{B}$. Note that the choices for $\vec{B}$ start at the end of vector $-\vec{A}$ rather than at its initial point.



13 • **[SSM]** Is it possible for three equal magnitude vectors to add to zero? If so, sketch a graphical answer. If not, explain why not.

Determine the Concept In order for the three equal magnitude vectors to add to zero, the sum of the three vectors must form a triangle. The equilateral triangle shown to the right satisfies this condition for the vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$ for which it is true that $A = B = C$, whereas $\vec{A}+\vec{B}+\vec{C}=0$.



Estimation and Approximation

14 • The angle subtended by the moon's diameter at a point on Earth is about 0.524° (Fig. 1-2). Use this and the fact that the moon is about 384 Mm away to find the diameter of the moon. *HINT: The angle can be determined from the diameter of the moon and the distance to the moon.*

Picture the Problem Let θ represent the angle subtended by the moon's diameter, D represent the diameter of the moon, and r_m the distance to the moon. Because θ is small, we can approximate it by $\theta \approx D/r_m$ where θ is in radian measure. We can solve this relationship for the diameter of the moon.

Express the moon's diameter D in terms of the angle it subtends at Earth θ and the Earth-moon distance r_m:

$$D = \theta r_m$$

Substitute numerical values and evaluate D:

$$D = \left(0.524° \times \frac{2\pi\ \text{rad}}{360°}\right)(384\ \text{Mm})$$

$$= \boxed{3.51\times10^{6}\ \text{m}}$$

15 • [SSM] Some good estimates about the human body can be made if it is assumed that we are made mostly of water. The mass of a water molecule is 29.9×10^{-27} kg. If the mass of a person is 60 kg, estimate the number of water molecules in that person.

Picture the Problem We can estimate the number of water molecules in a person whose mass is 60 kg by dividing this mass by the mass of a single water molecule.

Letting N represent the number of water molecules in a person of mass $m_{\text{human body}}$, express N in terms of $m_{\text{human body}}$ and the mass of a water molecule $m_{\text{water molecule}}$:

$$N = \frac{m_{\text{human body}}}{m_{\text{water molecule}}}$$

Substitute numerical values and evaluate N:

$$N = \frac{60\ \text{kg}}{29.9 \times 10^{-27}\ \dfrac{\text{kg}}{\text{molecule}}} = \boxed{2.0 \times 10^{27}\ \text{molecules}}$$

16 •• In 1989, IBM scientists figured out how to move atoms with a scanning tunneling microscope (STM). One of the first STM pictures seen by the general public was of the letters IBM spelled with xenon atoms on a nickel surface. The letters IBM were 15 xenon atoms across. If the space between the centers of adjacent xenon atoms is 5 nm (5×10^{-9} m), estimate how many times could ″IBM″ could be written across this 8.5 inch page.

Picture the Problem We can estimate the number of times N that ″IBM″ could be written across this 8.5-inch page by dividing the width w of the page by the distance d required by each writing of ″IBM.″

Express N in terms of the width w of the page and the distance d required by each writing of ″IBM″:

$$N = \frac{w}{d}$$

Express d in terms of the separation s of the centers of adjacent xenon atoms and the number n of xenon atoms in each writing of ″IBM″:

$$d = sn$$

Substitute for d in the expression for N to obtain:

$$N = \frac{w}{sn}$$

Substitute numerical values and evaluate N:

$$N=\frac{(8.5\text{ in})\left(2.540\,\frac{\text{cm}}{\text{in}}\right)}{\left(5\text{ nm}\times\frac{10^{-9}\text{ m}}{\text{nm}}\right)(15)}=\boxed{3\times10^{6}}$$

17 •• There is an environmental debate over the use of cloth versus disposable diapers. (*a*) If we assume that between birth and 2.5 y of age, a child uses 3 diapers per day, estimate the total number of disposable diapers used in the United States per year. (*b*) Estimate the total landfill volume due to these diapers, assuming that 1000 kg of waste fills about 1 m^3 of landfill volume. (*c*) How many square miles of landfill area at an average height of 10 m is needed for the disposal of diapers each year?

Picture the Problem We'll assume a population of 300 million and a life expectancy of 76 y. We'll also assume that a diaper has a volume of about half a liter. In (*c*) we'll assume the disposal site is a rectangular hole in the ground and use the formula for the volume of such an opening to estimate the surface area required.

(*a*) Express the total number N of disposable diapers used in the United States per year in terms of the number of children n in diapers and the number of diapers D used by each child per year:

$$N=nD \qquad (1)$$

Use the estimated daily consumption and the number of days in a year to estimate the number of diapers D required per child per year:

$$D=\frac{3\,\text{diapers}}{\text{child}\cdot\text{d}}\times\frac{365.24\,\text{d}}{\text{y}}$$
$$\approx1.1\times10^{3}\text{ diapers/child}\cdot\text{y}$$

Use the assumed life expectancy to estimate the number of children n in diapers yearly:

$$n=\left(\frac{2.5\,\text{y}}{76\,\text{y}}\right)\left(300\times10^{6}\text{ children}\right)$$
$$\approx10^{7}\text{ children}$$

Substitute numerical values in equation (1) to obtain:

$$N=\left(10^{7}\text{ children}\right)\left(3\times10^{3}\,\frac{\text{diapers}}{\text{y}}\right)$$
$$\approx\boxed{1.1\times10^{10}\text{ diapers}}$$

(*b*) Express the required landfill volume V in terms of the volume of diapers to be buried:

$$V = NV_{\text{one diaper}}$$

Substitute numerical values and evaluate V:

$$V = \left(1.1\times10^{10}\text{ diapers}\right)\left(\frac{0.5\,\text{L}}{\text{diaper}}\times\frac{10^{-3}\text{ m}^3}{\text{L}}\right)\approx\boxed{5.5\times10^{6}\text{ m}^3}$$

(*c*) Express the required volume in terms of the volume of a rectangular parallelepiped:

$$V = Ah \Rightarrow A = \frac{V}{h}$$

Substitute numerical values evaluate A:

$$A = \frac{5.5\times10^{6}\text{ m}^3}{10\,\text{m}} = 5.5\times10^{5}\text{ m}^2$$

Use a conversion factor (see Appendix A) to express this area in square miles:

$$A = 5.5\times10^{5}\text{ m}^2\times\frac{0.3861\text{ mi}^2}{1\,\text{km}^2}$$

$$\approx\boxed{0.2\,\text{mi}^2}$$

18 •• (*a*) Estimate the number of gallons of gasoline used per day by automobiles in the United States and the total amount of money spent on it. (*b*) If 19.4 gal of gasoline can be made from one barrel of crude oil, estimate the total number of barrels of oil imported into the United States per year to make gasoline. How many barrels per day is this?

Picture the Problem The population of the United States is roughly 3×10^8 people. Assuming that the average family has four people, with an average of two cars per family, there are about 1.5×10^8 cars in the United States. If we double that number to include trucks, cabs, etc., we have 3×10^8 vehicles. Let's assume that each vehicle uses, on average, 14 gallons of gasoline per week and that the United States imports half its oil.

(*a*) Find the daily consumption of gasoline G:

$$G = \left(3\times10^{8}\text{ vehicles}\right)\left(2\,\text{gal/d}\right)$$

$$= 6\times10^{8}\text{ gal/d}$$

Assuming a price per gallon P = \$3.00, find the daily cost C of gasoline:

$$C = GP = \left(6\times10^{8}\text{ gal/d}\right)\left(\$3.00/\text{gal}\right)$$

$$= \$18\times10^{8}/\text{d}$$

$$\approx\boxed{2\text{ billion dollars/d}}$$

(*b*) Relate the number of barrels N of crude oil imported annually to the yearly consumption of gasoline Y and the number of gallons of gasoline n that can be made from one barrel of crude oil:

$$N = \frac{fY}{n} = \frac{fG\Delta t}{n}$$

where f is the fraction of the oil that is imported.

Substitute numerical values and estimate N:

$$N = \frac{(0.5)\left(6\times10^{8}\,\frac{\text{gallons}}{\text{d}}\right)\left(365.24\,\frac{\text{d}}{\text{y}}\right)}{19.4\,\frac{\text{gallons}}{\text{barrel}}} \approx \boxed{6\times10^{9}\,\frac{\text{barrels}}{\text{y}}}$$

Convert barrels/y to barrels/d to obtain:

$$N = 6\times10^{9}\,\frac{\text{barrels}}{\text{y}}\times\frac{1\,\text{y}}{365.24\,\text{d}} \approx \boxed{2\times10^{7}\,\frac{\text{barrels}}{\text{d}}}$$

19 •• [SSM] A megabyte (MB) is a unit of computer memory storage. A CD has a storage capacity of 700 MB and can store approximately 70 min of high-quality music. (*a*) If a typical song is 5 min long, how many megabytes are required for each song? (*b*) If a page of printed text takes approximately 5 kilobytes, estimate the number of novels that could be saved on a CD.

Picture the Problem We can set up a proportion to relate the storage capacity of a CD to its playing time, the length of a typical song, and the storage capacity required for each song. In (*b*) we can relate the number of novels that can be stored on a CD to the number of megabytes required per novel and the storage capacity of the CD.

(*a*) Set up a proportion relating the ratio of the number of megabytes on a CD to its playing time to the ratio of the number of megabytes N required for each song:

$$\frac{700\,\text{MB}}{70\,\text{min}} = \frac{N}{5\,\text{min}}$$

Solve this proportion for N to obtain:

$$N = \left(\frac{700\,\text{MB}}{70\,\text{min}}\right)(5\,\text{min}) = \boxed{50\,\text{MB}}$$

(*b*) Letting *n* represent the number of megabytes per novel, express the number of novels N_{novels} that can be stored on a CD in terms of the storage capacity of the CD:

$$N_{\text{novels}} = \frac{700\ \text{MB}}{n}$$

Assuming that a typical page in a novel requires 5 kB of memory, express *n* in terms of the number of pages *p* in a typical novel:

$$n = \left(5\,\frac{\text{kB}}{\text{page}}\right)p$$

Substitute for *n* in the expression for N_{novels} to obtain:

$$N_{\text{novels}} = \frac{700\ \text{MB}}{\left(5\,\frac{\text{kB}}{\text{page}}\right)p}$$

Assuming that a typical novel has 200 pages:

$$N_{\text{novels}} = \frac{700\ \text{MB} \times \frac{10^3\ \text{kB}}{\text{MB}}}{\left(5\,\frac{\text{kB}}{\text{page}}\right)\left(200\,\frac{\text{pages}}{\text{novel}}\right)} = \boxed{7\times10^2\ \text{novels}}$$

Units

20 • Express the following quantities using the prefixes listed in Table 1-1 and the unit abbreviations listed in the table Abbreviations for Units. For example, 10,000 meters = 10 km. (*a*) 1,000,000 watts, (*b*) 0.002 gram, (*c*) 3 × 10^{-6} meter, (*d*) 30,000 seconds.

Picture the Problem We can use the metric prefixes listed in Table 1-1 and the abbreviations on page EP-1 to express each of these quantities.

(*a*)

$$1{,}000{,}000\ \text{watts} = 10^6\ \text{watts} = \boxed{1\,\text{MW}}$$

(*c*)

$$3\times10^{-6}\ \text{meter} = \boxed{3\ \mu\text{m}}$$

(*b*)

$$0.002\,\text{gram} = 2\times10^{-3}\ \text{g} = \boxed{2\,\text{mg}}$$

(*d*)

$$30{,}000\,\text{seconds} = 30\times10^{3}\ \text{s} = \boxed{30\,\text{ks}}$$

21 • Write each of the following without using prefixes: (*a*) 40 μW, (*b*) 4 ns, (*c*) 3 MW, (*d*) 25 km.

Picture the Problem We can use the definitions of the metric prefixes listed in Table 1-1 to express each of these quantities without prefixes.

(*a*)
$$40\ \mu\text{W} = 40 \times 10^{-6}\ \text{W} = \boxed{0.000040\ \text{W}}$$

(*b*)
$$4\ \text{ns} = 4 \times 10^{-9}\ \text{s} = \boxed{0.000000004\ \text{s}}$$

(*c*)
$$3\ \text{MW} = 3 \times 10^{6}\ \text{W} = \boxed{3{,}000{,}000\ \text{W}}$$

(*d*)
$$25\ \text{km} = 25 \times 10^{3}\ \text{m} = \boxed{25{,}000\ \text{m}}$$

22 • Write the following (which are not SI units) using prefixes (but not their abbreviations). For example, 10^3 meters = 1 kilometer: (*a*) 10^{-12} boo, (*b*) 10^9 low, (*c*) 10^{-6} phone, (*d*) 10^{-18} boy, (*e*) 10^6 phone, (*f*) 10^{-9} goat, (*g*) 10^{12} bull.

Picture the Problem We can use the definitions of the metric prefixes listed in Table 1-1 to express each of these quantities without abbreviations.

(*a*) $10^{-12}\ \text{boo} = \boxed{1\ \text{picoboo}}$

(*b*) $10^{9}\ \text{low} = \boxed{1\ \text{gigalow}}$

(*c*) $10^{-6}\ \text{phone} = \boxed{1\ \text{microphone}}$

(*d*) $10^{-18}\ \text{boy} = \boxed{1\ \text{attoboy}}$

(*e*) $10^{6}\ \text{phone} = \boxed{1\ \text{megaphone}}$

(*f*) $10^{-9}\ \text{goat} = \boxed{1\ \text{nanogoat}}$

(*g*) $10^{12}\ \text{bull} = \boxed{1\ \text{terabull}}$

23 •• **[SSM]** In the following equations, the distance x is in meters, the time t is in seconds, and the velocity v is in meters per second. What are the SI units of the constants C_1 and C_2? (*a*) $x = C_1 + C_2t$, (*b*) $x = \frac{1}{2}C_1t^2$, (*c*) $v^2 = 2C_1x$, (*d*) $x = C_1 \cos C_2t$, (*e*) $v^2 = 2C_1v - (C_2x)^2$.

Picture the Problem We can determine the SI units of each term on the right-hand side of the equations from the units of the physical quantity on the left-hand side.

(*a*) Because x is in meters, C_1 and C_2t must be in meters:

$$\boxed{C_1 \text{ is in m; } C_2 \text{ is in m/s}}$$

(*b*) Because x is in meters, $\frac{1}{2}C_1t^2$ must be in meters:

$$\boxed{C_1 \text{ is in m/s}^2}$$

(*c*) Because v^2 is in m^2/s^2, $2C_1x$ must be in m^2/s^2:

$$\boxed{C_1 \text{ is in m/s}^2}$$

(*d*) The argument of a trigonometric function must be dimensionless; i.e. without units. Therefore, because x is in meters:

$$\boxed{C_1 \text{ is in m}; C_2 \text{ is in s}^{-1}}$$

(*e*) All of the terms in the expression must have the same units. Therefore, because v is in m/s:

$$\boxed{C_1 \text{ is in m/s}; C_2 \text{ is in s}^{-1}}$$

24 •• If x is in feet, t is in milliseconds, and v is in feet per second, what are the units of the constants C_1 and C_2 in each part of Problem 23?

Picture the Problem We can determine the US customary units of each term on the right-hand side of the equations from the units of the physical quantity on the left-hand side.

(*a*) Because x is in feet, C_1 and C_2t must be in feet:

$$\boxed{C_1 \text{ is in ft}; C_2 \text{ is in ft/ms}}$$

(*b*) Because x is in feet, $\frac{1}{2}\boldsymbol{C_1t^2}$ must be in feet:

$$\boxed{C_1 \text{ is in ft}/(\text{ms})^2}$$

(*c*) Because v^2 is in $\text{ft}^2/(\text{ms})^2$, $2C_1x$ must be in ft^2/s^2:

$$\boxed{C_1 \text{ is in ft}/(\text{ms})^2}$$

(*d*) The argument of a trigonometric function must be dimensionless; that is, without units. Therefore, because x is in feet:

$$\boxed{C_1 \text{ is in ft}; C_2 \text{ is in } (\text{ms})^{-1}}$$

(*e*) The argument of an exponential function must be dimensionless; that is, without units. Therefore, because v is in ft/s:

$$\boxed{C_1 \text{ is in ft/ms}; C_2 \text{ is in } (\text{ms})^{-1}}$$

Conversion of Units

25 • From the original definition of the meter in terms of the distance along a meridian from the equator to the North Pole, find in meters (*a*) the circumference of Earth and (*b*) the radius of Earth. (*c*) Convert your answers for (*a*) and (*b*) from meters into miles.

Picture the Problem We can use the formula for the circumference of a circle to find the radius of Earth and the conversion factor 1 mi = 1.609 km to convert distances in meters into distances in miles.

(*a*) The Pole-Equator distance is one-fourth of the circumference:

$$C = 4D_{\text{pole-equator}} = \boxed{4\times 10^{7}\ \text{m}}$$

(*b*) The formula for the circumference of a circle is:

$$C = \pi D = 2\pi R \Rightarrow R = \frac{C}{2\pi}$$

Substitute numerical values and evaluate *R*:

$$R = \frac{4\times 10^{7}\ \text{m}}{2\pi} = 6.37\times 10^{6}\ \text{m}$$
$$= \boxed{6\times 10^{6}\ \text{m}}$$

(*c*) Use the conversion factors 1 km = 1000 m and 1 mi = 1.609 km to express *C* in mi:

$$C = 4\times 10^{7}\ \text{m}\times\frac{1\,\text{km}}{10^{3}\ \text{m}}\times\frac{1\,\text{mi}}{1.609\,\text{km}}$$
$$= \boxed{2\times 10^{4}\ \text{mi}}$$

Use the conversion factors 1 km = 1000 m and 1 mi = 1.61 km to express *R* in mi:

$$R = 6.37\times 10^{6}\ \text{m}\times\frac{1\text{km}}{10^{3}\ \text{m}}\times\frac{1\text{mi}}{1.609\,\text{km}}$$
$$= \boxed{4\times 10^{3}\ \text{mi}}$$

26 • The speed of sound in air is 343 m/s at normal room temperature. What is the speed of a supersonic plane that travels at twice the speed of sound? Give your answer in kilometers per hour and miles per hour.

Picture the Problem We can use the conversion factor 1 mi = 1.61 km to convert speeds in km/h into mi/h.

Find the speed of the plane in km/h:

$$v = 2(343\,\text{m/s}) = 686\,\text{m/s}$$
$$= \left(686\frac{\text{m}}{\text{s}}\right)\left(\frac{1\text{km}}{10^{3}\ \text{m}}\right)\left(3600\frac{\text{s}}{\text{h}}\right)$$
$$= \boxed{2.47\times 10^{3}\ \text{km/h}}$$

Convert v into mi/h:

$$v = \left(2.47\times10^3\ \frac{\text{km}}{\text{h}}\right)\left(\frac{1\,\text{mi}}{1.609\,\text{km}}\right) = \boxed{1.53\times10^3\ \text{mi/h}}$$

27 • A basketball player is 6 ft $10\frac{1}{2}$ in tall. What is his height in centimeters?

Picture the Problem We'll first express his height in inches and then use the conversion factor 1 in = 2.540 cm.

Express the player's height in inches:

$$h = 6\,\text{ft}\times\frac{12\,\text{in}}{\text{ft}} + 10.5\,\text{in} = 82.5\,\text{in}$$

Convert h into cm:

$$h = 82.5\,\text{in}\times\frac{2.540\,\text{cm}}{\text{in}} = \boxed{210\,\text{cm}}$$

28 • Complete the following: (a) 100 km/h = ____ mi/h, (b) 60 cm = ____ in, (c) 100 yd = ____ m.

Picture the Problem We can use the conversion factors 1 mi = 1.609 km, 1 in = 2.540 cm, and 1 m = 1.094 yd to perform these conversions.

(a) Convert $100\frac{\text{km}}{\text{h}}$ to $\frac{\text{mi}}{\text{h}}$:

$$100\frac{\text{km}}{\text{h}} = 100\frac{\text{km}}{\text{h}}\times\frac{1\,\text{mi}}{1.609\,\text{km}} = \boxed{62.2\,\text{mi/h}}$$

(b) Convert 60 cm to in:

$$60\,\text{cm} = 60\,\text{cm}\times\frac{1\,\text{in}}{2.540\,\text{cm}} = 23.6\,\text{in} = \boxed{24\,\text{in}}$$

(c) Convert 100 yd to m:

$$100\,\text{yd} = 100\,\text{yd}\times\frac{1\,\text{m}}{1.094\,\text{yd}} = \boxed{91.4\,\text{m}}$$

29 • The main span of the Golden Gate Bridge is 4200 ft. Express this distance in kilometers.

Picture the Problem We can use the conversion factor 1.609 km = 5280 ft to convert the length of the main span of the Golden Gate Bridge into kilometers.

Convert 4200 ft into km by multiplying by 1 in the form $\frac{1.609\text{ km}}{5280\text{ ft}}$:

$$4200\,\text{ft} = 4200\,\text{ft}\times\frac{1.609\,\text{km}}{5280\,\text{ft}} = \boxed{1.28\,\text{km}}$$

30 • Find the conversion factor to convert from miles per hour into kilometers per hour.

Picture the Problem Let v be the speed of an object in mi/h. We can use the conversion factor 1 mi = 1.609 km to convert this speed to km/h.

Multiply v mi/h by 1.609 km/mi to convert v to km/h:

$$v\frac{\text{mi}}{\text{h}} = v\frac{\text{mi}}{\text{h}}\times\frac{1.609\,\text{km}}{\text{mi}} = \boxed{1.61v\,\text{km/h}}$$

31 • Complete the following: (*a*) 1.296×10^5 km/h^2 = ____ km/(h·s), (*b*) 1.296×10^5 km/h^2 = ____m/s^2, (*c*) 60 mi/h = ____ ft/s, (*d*) 60 mi/h = ____ m/s.

Picture the Problem Use the conversion factors 1 h = 3600 s, 1.609 km = 1 mi, and 1 mi = 5280 ft to make these conversions.

(*a*) $$1.296\times10^5\frac{\text{km}}{\text{h}^2} = \left(1.296\times10^5\frac{\text{km}}{\text{h}^2}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right) = \boxed{36.00\,\text{km/h}\cdot\text{s}}$$

(*b*) $$1.296\times10^5\frac{\text{km}}{\text{h}^2} = \left(1.296\times10^5\frac{\text{km}}{\text{h}^2}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)^2\left(\frac{10^3\,\text{m}}{\text{km}}\right) = \boxed{10.00\,\text{m/s}^2}$$

(*c*) $$60\frac{\text{mi}}{\text{h}} = \left(60\frac{\text{mi}}{\text{h}}\right)\left(\frac{5280\,\text{ft}}{1\,\text{mi}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right) = \boxed{88\,\text{ft/s}}$$

(*d*) $$60\frac{\text{mi}}{\text{h}} = \left(60\frac{\text{mi}}{\text{h}}\right)\left(\frac{1.609\,\text{km}}{1\,\text{mi}}\right)\left(\frac{10^3\,\text{m}}{\text{km}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right) = 26.8\,\text{m/s} = \boxed{27\,\text{m/s}}$$

32 • There are 640 acres in a square mile. How many square meters are there in one acre?

Picture the Problem We can use the conversion factor given in the problem statement and the fact that 1 mi = 1.609 km to express the number of square meters in one acre. Note that, because there are exactly 640 acres in a square mile, 640 acres has as many significant figures as we may wish to associate with it.

Multiply by 1 twice, properly chosen, to convert one acre into square miles, and then into square meters:

$$1\,\text{acre} = (1\,\text{acre})\left(\frac{1\,\text{mi}^2}{640\,\text{acres}}\right)\left(\frac{1609\,\text{m}}{\text{mi}}\right)^2$$
$$= \boxed{4045\,\text{m}^2}$$

33 •• [SSM] You are a delivery person for the Fresh Aqua Spring Water Company. Your truck carries 4 pallets. Each pallet carries 60 cases of water. Each case of water has 24 one-liter bottles. You are to deliver 10 cases of water to each convenience store along your route. The dolly you use to carry the water into the stores has a weight limit of 250 lb. (*a*) If a milliliter of water has a mass of 1 g, and a kilogram has a weight of 2.2 lb, what is the weight, in pounds, of all the water in your truck? (*b*) How many full cases of water can you carry on the cart?

Picture the Problem The weight of the water in the truck is the product of the volume of the water and its weight density of 2.2 lb/L.

(*a*) Relate the weight w of the water on the truck to its volume V and weight density (weight per unit volume) D:

$$w = DV$$

Find the volume V of the water:

$$V = (4\text{ pallets})\left(60\,\frac{\text{cases}}{\text{pallet}}\right)\left(24\,\frac{\text{L}}{\text{case}}\right)$$
$$= 5760\text{ L}$$

Substitute numerical values for D and L and evaluate w:

$$w = \left(2.2\,\frac{\text{lb}}{\text{L}}\right)(5760\text{ L}) = 1.267\times10^4\text{ lb}$$
$$= \boxed{1.3\times10^4\text{ lb}}$$

(*b*) Express the number of cases of water in terms of the weight limit of the cart and the weight of each case of water:

$$N = \frac{\text{weight limit of the cart}}{\text{weight of each case of water}}$$

Substitute numerical values and evaluate N:

$$N = \frac{250\text{ lb}}{\left(2.2\,\frac{\text{lb}}{\text{L}}\right)\left(24\,\frac{\text{L}}{\text{case}}\right)} = 4.7\text{ cases}$$

$$\boxed{\text{You can carry 4 cases.}}$$

34 •• A right circular cylinder has a diameter of 6.8 in and a height of 2.0 ft. What is the volume of the cylinder in (*a*) cubic feet, (*b*) cubic meters, (*c*) liters?

Picture the Problem The volume of a right circular cylinder is the area of its base multiplied by its height. Let *d* represent the diameter and *h* the height of the right circular cylinder; use conversion factors to express the volume *V* in the given units.

(*a*) Express the volume of the cylinder:

$$V = \tfrac{1}{4}\pi d^2 h$$

Substitute numerical values and evaluate *V*:

$$V = \tfrac{1}{4}\pi(6.8\,\text{in})^2(2.0\,\text{ft})$$
$$= \tfrac{1}{4}\pi(6.8\,\text{in})^2(2.0\,\text{ft})\left(\frac{1\,\text{ft}}{12\,\text{in}}\right)^2$$
$$= 0.504\,\text{ft}^3 = \boxed{0.50\,\text{ft}^3}$$

(*b*) Use the fact that 1 m = 3.281 ft to convert the volume in cubic feet into cubic meters:

$$V = \left(0.504\,\text{ft}^3\right)\left(\frac{1\,\text{m}}{3.281\,\text{ft}}\right)^3 = 0.0143\,\text{m}^3$$
$$= \boxed{0.014\,\text{m}^3}$$

(*c*) Because 1 L = 10^{-3} m^3:

$$V = \left(0.0143\,\text{m}^3\right)\left(\frac{1\,\text{L}}{10^{-3}\,\text{m}^3}\right) = \boxed{14\,\text{L}}$$

35 •• **[SSM]** In the following, *x* is in meters, *t* is in seconds, *v* is in meters per second, and the acceleration *a* is in meters per second squared. Find the SI units of each combination: (*a*) v^2/x, (*b*) $\sqrt{x/a}$, (*c*) $\tfrac{1}{2}at^2$.

Picture the Problem We can treat the SI units as though they are algebraic quantities to simplify each of these combinations of physical quantities and constants.

(*a*) Express and simplify the units of v^2/x:

$$\frac{(\text{m/s})^2}{\text{m}} = \frac{\text{m}^2}{\text{m}\cdot\text{s}^2} = \boxed{\frac{\text{m}}{\text{s}^2}}$$

(*b*) Express and simplify the units of $\sqrt{x/a}$:

$$\sqrt{\frac{\text{m}}{\text{m/s}^2}} = \sqrt{\text{s}^2} = \boxed{\text{s}}$$

(*c*) Noting that the constant factor $\frac{1}{2}$ has no units, express and simplify the units of $\frac{1}{2}at^2$:

$$\left(\frac{\text{m}}{\text{s}^2}\right)(\text{s})^2 = \boxed{\text{m}}$$

Dimensions of Physical Quantities

36 • What are the dimensions of the constants in each part of Problem 23?

Picture the Problem We can use the facts that each term in an equation must have the same dimensions and that the arguments of a trigonometric or exponential function must be dimensionless to determine the dimensions of the constants.

(*a*)

$$\begin{array}{ccccc} x & = & C_1 & + & C_2 \quad t \\ \text{L} & & \boxed{\text{L}} & & \boxed{\frac{\text{L}}{\text{T}}}\ \text{T} \end{array}$$

(*b*)

$$\begin{array}{cccc} x & = & \frac{1}{2} & C_1 \quad t^2 \\ \text{L} & & & \boxed{\frac{\text{L}}{\text{T}^2}}\ \text{T}^2 \end{array}$$

(*c*)

$$\begin{array}{ccc} v^2 & = & 2\ C_1 \quad x \\ \frac{\text{L}^2}{\text{T}^2} & & \boxed{\frac{\text{L}}{\text{T}^2}}\ \text{L} \end{array}$$

(*d*)

$$\begin{array}{ccc} x & = & C_1 \ \cos\ C_2 \quad t \\ \text{L} & & \boxed{\text{L}} \quad \boxed{\frac{1}{\text{T}}}\ \text{T} \end{array}$$

(*e*)

$$\begin{array}{ccccc} v^2 & = & 2\ C_1\ v & - & (C_2)^2\ x^2 \\ \left(\frac{\text{L}}{\text{T}}\right)^2 & & \boxed{\frac{\text{L}}{\text{T}}}\ \frac{\text{L}}{\text{T}} & & \boxed{\frac{1}{\text{T}}}\ \text{L}^2 \end{array}$$

37 • The law of radioactive decay is $N(t) = N_0 e^{-\lambda t}$, where N_0 is the number of radioactive nuclei at $t = 0$, $N(t)$ is the number remaining at time t, and λ is a quantity known as the decay constant. What is the dimension of λ?

Picture the Problem Because the exponent of the exponential function must be dimensionless, the dimension of λ must be $\boxed{\text{T}^{-1}.}$

38 •• The SI unit of force, the kilogram-meter per second squared (kg·m/s^2) is called the newton (N). Find the dimensions and the SI units of the constant G in Newton's law of gravitation $F = Gm_1m_2/r^2$.

Picture the Problem We can solve Newton's law of gravitation for G and substitute the dimensions of the variables. Treating them as algebraic quantities will allow us to express the dimensions in their simplest form. Finally, we can substitute the SI units for the dimensions to find the units of G.

Solve Newton's law of gravitation for G to obtain:

$$G = \frac{Fr^2}{m_1 m_2}$$

Substitute the dimensions of the variables:

$$[G] = \frac{\frac{\text{ML}}{\text{T}^2} \times \text{L}^2}{\text{M}^2} = \boxed{\frac{\text{L}^3}{\text{MT}^2}}$$

Use the SI units for L, M, and T to obtain:

$$\boxed{\frac{\text{m}^3}{\text{kg}\cdot\text{s}^2}}$$

39 •• The magnitude of the force (F) that a spring exerts when it is stretched a distance x from its unstressed length is governed by Hooke's law, $F = kx$. (a) What are the dimensions of the *force constant*, k? (b) What are the dimensions and SI units of the quantity kx^2?

Picture the Problem The dimensions of mass and velocity are M and L/T, respectively. We note from Table 1-2 that the dimensions of force are ML/T^2.

(a) We know, from Hooke's law, that:

$$k = \frac{F}{x}$$

Write the corresponding dimensional equation:

$$[k] = \frac{[F]}{[x]}$$

Substitute the dimensions of F and x and simplify to obtain:

$$[k] = \frac{\text{M}\frac{\text{L}}{\text{T}^2}}{\text{L}} = \boxed{\frac{\text{M}}{\text{T}^2}}$$

(b) Substitute the dimensions of k and x^2 and simplify to obtain:

$$[kx^2] = \frac{\text{M}}{\text{T}^2}\text{L}^2 = \boxed{\frac{\text{ML}^2}{\text{T}^2}}$$

Substitute the units of kx^2 to obtain:

$$\boxed{\frac{\text{kg}\cdot\text{m}^2}{\text{s}^2}}$$

40 •• Show that the product of mass, acceleration, and speed has the dimensions of power.

Picture the Problem We note from Table 1-2 that the dimensions of power are ML^2/T^3. The dimensions of mass, acceleration, and speed are M, L/T^2, and L/T respectively.

Express the dimensions of mav:

$$[mav] = \mathrm{M} \times \frac{\mathrm{L}}{\mathrm{T}^2} \times \frac{\mathrm{L}}{\mathrm{T}} = \frac{\mathrm{ML}^2}{\mathrm{T}^3}$$

From Table 1-2:

$$[P] = \frac{\mathrm{ML}^2}{\mathrm{T}^3}$$

Comparing these results, we see that the product of mass, acceleration, and speed has the dimensions of power.

41 •• **[SSM]** The momentum of an object is the product of its velocity and mass. Show that momentum has the dimensions of force multiplied by time.

Picture the Problem The dimensions of mass and velocity are M and L/T, respectively. We note from Table 1-2 that the dimensions of force are $\mathrm{ML/T^2}$.

Express the dimensions of momentum:

$$[mv] = \mathrm{M} \times \frac{\mathrm{L}}{\mathrm{T}} = \frac{\mathrm{ML}}{\mathrm{T}}$$

From Table 1-2:

$$[F] = \frac{\mathrm{ML}}{\mathrm{T}^2}$$

Express the dimensions of force multiplied by time:

$$[Ft] = \frac{\mathrm{ML}}{\mathrm{T}^2} \times \mathrm{T} = \frac{\mathrm{ML}}{\mathrm{T}}$$

Comparing these results, we see that momentum has the dimensions of force multiplied by time.

42 •• What combination of force and one other physical quantity has the dimensions of power?

Picture the Problem Let X represent the physical quantity of interest. Then we can express the dimensional relationship between F, X, and P and solve this relationship for the dimensions of X.

Express the relationship of X to force and power dimensionally:

$$[F][X]=[P]$$

Solve for $[X]$:

$$[X]=\frac{[P]}{[F]}$$

Substitute the dimensions of force and power and simplify to obtain:

$$[X]=\frac{\frac{\mathrm{ML}^2}{\mathrm{T}^3}}{\frac{\mathrm{ML}}{\mathrm{T}^2}}=\frac{\mathrm{L}}{\mathrm{T}}$$

Because the dimensions of velocity are L/T*,* we can conclude that:

$$[P]=\boxed{[F][v]}$$

Remarks: While it is true that *P* = *Fv*, dimensional analysis does not reveal the presence of dimensionless constants. For example, if $P=\pi Fv$, the analysis shown above would fail to establish the factor of π.

43 •• [SSM] When an object falls through air, there is a drag force that depends on the product of the cross sectional area of the object and the square of its velocity, that is, $F_{\text{air}} = CAv^2$, where C is a constant. Determine the dimensions of C.

Picture the Problem We can find the dimensions of C by solving the drag force equation for C and substituting the dimensions of force, area, and velocity.

Solve the drag force equation for the constant C:

$$C=\frac{F_{\text{air}}}{Av^2}$$

Express this equation dimensionally:

$$[C]=\frac{[F_{\text{air}}]}{[A][v]^2}$$

Substitute the dimensions of force, area, and velocity and simplify to obtain:

$$[C]=\frac{\frac{\mathrm{ML}}{\mathrm{T}^2}}{\mathrm{L}^2\left(\frac{\mathrm{L}}{\mathrm{T}}\right)^2}=\boxed{\frac{\mathrm{M}}{\mathrm{L}^3}}$$

44 •• Kepler's third law relates the period of a planet to its orbital radius r, the constant G in Newton's law of gravitation ($F = Gm_1m_2/r^2$), and the mass of the sun M_s. What combination of these factors gives the correct dimensions for the period of a planet?

Picture the Problem We can express the period of a planet as the product of the factors *r, G,* and M_S (each raised to a power) and then perform dimensional analysis to determine the values of the exponents.

Express the period T of a planet as the product of $r^a, G^b, \text{and } M_S^c$:

$$T = Cr^aG^bM_S^c \qquad (1)$$

where C is a dimensionless constant.

Solve the law of gravitation for the constant G:

$$G = \frac{Fr^2}{m_1m_2}$$

Express this equation dimensionally:

$$[G] = \frac{[F][r]^2}{[m_1][m_2]}$$

Substitute the dimensions of F, r, and m:

$$[G] = \frac{\frac{\text{ML}}{\text{T}^2}\times(\text{L})^2}{\text{M}\times\text{M}} = \frac{\text{L}^3}{\text{MT}^2}$$

Noting that the dimension of time is represented by the same letter as is the period of a planet, substitute the dimensions in equation (1) to obtain:

$$T = (\text{L})^a\left(\frac{\text{L}^3}{\text{MT}^2}\right)^b(\text{M})^c$$

Introduce the product of M^0 and L^0 in the left hand side of the equation and simplify to obtain:

$$\text{M}^0\text{L}^0\text{T}^1 = \text{M}^{c-b}\text{L}^{a+3b}\text{T}^{-2b}$$

Equating the exponents on the two sides of the equation yields:

$0 = c - b$, $0 = a + 3b$, and $1 = -2b$

Solve these equations simultaneously to obtain:

$$a = \tfrac{3}{2}, b = -\tfrac{1}{2}, \text{and } c = -\tfrac{1}{2}$$

Substitute for a, b, and c in equation (1) and simplify to obtain:

$$T = Cr^{3/2}G^{-1/2}M_S^{-1/2} = \boxed{\frac{C}{\sqrt{GM_S}}r^{3/2}}$$

Scientific Notation and Significant Figures

45 • **[SSM]** Express as a decimal number without using powers of 10 notation: (*a*) 3×10^4, (*b*) 6.2×10^{-3}, (*c*) 4×10^{-6}, (*d*) 2.17×10^5.

Picture the Problem We can use the rules governing scientific notation to express each of these numbers as a decimal number.

(*a*) $3\times 10^{4} = \boxed{30{,}000}$

(*b*) $6.2\times 10^{-3} = \boxed{0.0062}$

(*c*) $4\times 10^{-6} = \boxed{0.000004}$

(*d*) $2.17\times 10^{5} = \boxed{217{,}000}$

46 • Write the following in scientific notation: (*a*) 1345100 m = ____ km, (*b*) 12340. kW = ____ MW, (*c*) 54.32 ps = ____ s, (*d*) 3.0 m = ____ mm

Picture the Problem We can use the rules governing scientific notation to express each of these numbers in scientific notation.

(*a*)

$$1345100\text{ m} = 1.3451\times 10^{6}\text{ m}$$
$$= \boxed{1.3451\times 10^{3}\text{ km}}$$

(*b*)

$$12340.\text{ kW} = 1.2340\times 10^{4}\text{ kW}$$
$$= 1.2340\times 10^{7}\text{ W}$$
$$= \boxed{1.2340\times 10^{1}\text{ MW}}$$

(*c*)

$$54.32\text{ ps} = 54.32\times 10^{-12}\text{ s}$$
$$= \boxed{5.432\times 10^{-11}\text{ s}}$$

(*d*)

$$3.0\text{ m} = 3.0\text{ m}\times\frac{10^{3}\text{ mm}}{\text{m}}$$
$$= \boxed{3.0\times 10^{3}\text{ mm}}$$

47 • **[SSM]** Calculate the following, round off to the correct number of significant figures, and express your result in scientific notation: (*a*) $(1.14)(9.99\times 10^{4})$, (*b*) $(2.78\times 10^{-8}) - (5.31\times 10^{-9})$, (*c*) $12\pi/(4.56\times 10^{-3})$, (*d*) $27.6 + (5.99\times 10^{2})$.

Picture the Problem Apply the general rules concerning the multiplication, division, addition, and subtraction of measurements to evaluate each of the given expressions.

(*a*) The number of significant figures in each factor is three; therefore the result has three significant figures:

$$(1.14)(9.99\times 10^{4}) = \boxed{1.14\times 10^{5}}$$

(*b*) Express both terms with the same power of 10. Because the first measurement has only two digits after the decimal point, the result can have only two digits after the decimal point:

$$\left(2.78\times10^{-8}\right)-\left(5.31\times10^{-9}\right)=\left(2.78-0.531\right)\times10^{-8}=\boxed{2.25\times10^{-8}}$$

(*c*) We'll assume that 12 is exact. Hence, the answer will have three significant figures:

$$\frac{12\pi}{4.56\times10^{-3}}=\boxed{8.27\times10^{3}}$$

(*d*) Proceed as in (*b*):

$$27.6+\left(5.99\times10^{2}\right)=27.6+599=627=\boxed{6.27\times10^{2}}$$

48 • Calculate the following, round off to the correct number of significant figures, and express your result in scientific notation: (*a*) (200.9)(569.3), (*b*) (0.000000513)(62.3 × 10^7), (*c*) 28 401 + (5.78 × 10^4), (*d*) 63.25/(4.17 × 10^{-3}).

Picture the Problem Apply the general rules concerning the multiplication, division, addition, and subtraction of measurements to evaluate each of the given expressions.

(*a*) Note that both factors have four significant figures.

$$\left(200.9\right)\left(569.3\right)=\boxed{1.144\times10^{5}}$$

(*b*) Express the first factor in scientific notation and note that both factors have three significant figures.

$$\left(0.000000513\right)\left(62.3\times10^{7}\right)=\left(5.13\times10^{-7}\right)\left(62.3\times10^{7}\right)=\boxed{3.20\times10^{2}}$$

(*c*) Express both terms in scientific notation and note that the second has only three significant figures. Hence the result will have only three significant figures.

$$28401+\left(5.78\times10^{4}\right)=\left(2.841\times10^{4}\right)+\left(5.78\times10^{4}\right)=\left(2.841+5.78\right)\times10^{4}=\boxed{8.62\times10^{4}}$$

(*d*) Because the divisor has three significant figures, the result will have three significant figures.

$$\frac{63.25}{4.17\times10^{-3}}=\boxed{1.52\times10^{4}}$$

49 • [SSM] A cell membrane has a thickness of 7.0 nm. How many cell membranes would it take to make a stack 1.0 in high?

Picture the Problem Let *N* represent the required number of membranes and express *N* in terms of the thickness of each cell membrane.

Express *N* in terms of the thickness of a single membrane:

$$N=\frac{1.0\,\text{in}}{7.0\,\text{nm}}$$

Convert the units into SI units and simplify to obtain:

$$N=\frac{1.0\,\text{in}}{7.0\,\text{nm}}\times\frac{2.540\,\text{cm}}{\text{in}}\times\frac{1\,\text{m}}{100\,\text{cm}}\times\frac{1\,\text{nm}}{10^{-9}\,\text{m}}=3.63\times10^{6}=\boxed{3.6\times10^{6}}$$

50 •• A circular hole of radius 8.470×10^{-1} cm must be cut into the front panel of a display unit. The *tolerance* is 1.0×10^{-3} cm, which means the actual hole cannot differ by more than this much from the desired radius. If the actual hole is larger than the desired radius by the allowed tolerance, what is the difference between the actual area and the desired area of the hole?

Picture the Problem Let r_0 represent the larger radius and r the desired radius of the hole. We can find the difference between the actual and the desired area of the hole by subtracting the smaller area from the larger area.

Express the difference between the two areas in terms of r and r_0:

$$\Delta A=\pi r_0^2-\pi r^2=\pi\left(r_0^2-r^2\right)$$

Factoring $r_0^2-r^2$ to obtain:

$$\Delta A=\pi\left(r_0-r\right)\left(r_0+r\right)$$

Substitute numerical values and evaluate ΔA:

$$\begin{aligned}\Delta A&=\pi\left(1.0\times10^{-3}\text{ cm}\right)\left[8.470\times10^{-1}\text{ cm}+\left(8.470\times10^{-1}\text{ cm}+1.0\times10^{-3}\text{ cm}\right)\right]\\&=\boxed{5.3\times10^{-3}\text{ cm}^2}\end{aligned}$$

51 •• [SSM] A square peg must be made to fit through a square hole. If you have a square peg that has an edge length of 42.9 mm, and the square hole has an edge length of 43.2 mm, (*a*) what is the area of the space available when

the peg is in the hole? (*b*) If the peg is made rectangular by removing 0.10 mm of material from one side, what is the area available now?

Picture the Problem Let s_h represent the side of the square hole and s_p the side of the square peg. We can find the area of the space available when the peg is in the hole by subtracting the area of the peg from the area of the hole.

(*a*) Express the difference between the two areas in terms of s_h and s_p:

$$\Delta A = s_h^2 - s_p^2$$

Substitute numerical values and evaluate ΔA:

$$\Delta A = (43.2\text{ mm})^2 - (42.9\text{ mm})^2 \approx \boxed{26\text{ mm}^2}$$

(*b*) Express the difference between the area of the square hole and the rectangular peg in terms of s_h, s_p and the new length of the peg ℓ_p:

$$\Delta A' = s_h^2 - s_p \ell_p$$

Substitute numerical values and evaluate $\Delta A'$:

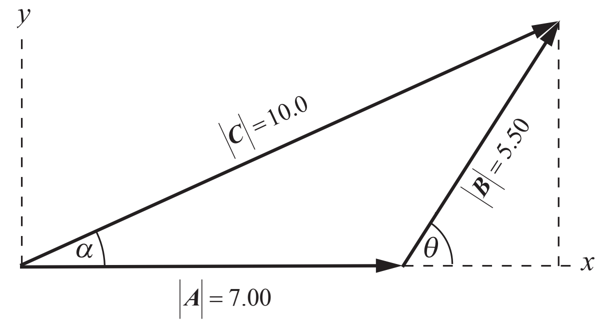
$$\Delta A' = (43.2\text{ mm})^2 - (42.9\text{ mm})(42.9\text{ mm} - 0.10\text{ mm}) \approx \boxed{30\text{ mm}^2}$$

Vectors and Their Properties

52 • A vector 7.00 units long and a vector 5.50 units long are added. Their sum is a vector 10.0 units long. (*a*) Show graphically at least one way that this can be accomplished. (*b*) Using your sketch in Part (*a*), determine the angle between the original two vectors.

Picture the Problem Let $\vec{A}$ be the vector whose length is 7.00 units and let $\vec{B}$ be the vector whose length is 5.50 units. $\vec{C} = \vec{A} + \vec{B}$ is the sum of $\vec{A}$ and $\vec{B}$. The fact that their sum is 10.0 long tells us that the vectors are not collinear. We can use the of the vectors to find the angle between $\vec{A}$ and $\vec{B}$.

(*a*) A graphical representation of vectors $\vec{A}$, $\vec{B}$ and $\vec{C}$ is shown below. θ is the angle between $\vec{A}$ and $\vec{B}$.



(*b*) The components of the vectors are related as follows:

$$A_x + B_x = C_x$$
and
$$A_y + B_y = C_y$$

Substituting for the components gives:

$$7.00 + (5.50)\cos\theta = (10.0)\cos\alpha$$
and
$$(5.50)\sin\theta = (10.0)\sin\alpha$$

Squaring and adding these equations yields:

$$(100)\sin^2\alpha + (100)\cos^2\alpha = (5.50)\sin^2\theta + [7.00 + (5.50)\cos\theta]^2$$

or

$$(100)(\sin^2\alpha + \cos^2\alpha) = (5.50)\sin^2\theta + [7.00 + (5.50)\cos\theta]^2$$

Because $\sin^2\alpha + \cos^2\alpha = 1$:

$$100 = (5.50)^2\sin^2\theta + [7.00 + (5.50)\cos\theta]^2$$

Solve this equation for θ (you can (1) use the same trigonometric identity used in the previous step to eliminate either $\sin^2\theta$ or $\cos^2\theta$ in favor of the other and then solve the resulting equation or (2) use your graphing calculator's SOLVER program) to obtain:

$$\theta = \boxed{74.4°}$$

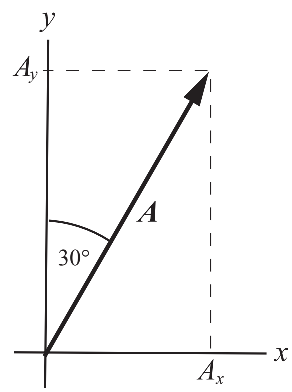
Remarks: You could also solve Part (*b*) of this problem by using the law of cosines.

53 • **[SSM]** Determine the *x* and *y* components of the following three vectors in the *xy* plane. (*a*) A 10-m displacement vector that makes an angle of 30° clockwise from the +*y* direction. (*b*) A 25-m/s velocity vector that makes an

angle of –40° counterclockwise from the –*x* direction. (*c*) A 40-lb force vector that makes an angle of 120° counterclockwise from the –*y* direction.

Picture the Problem The *x* and *y* components of these vectors are their projections onto the *x* and *y* axes. Note that the components are calculated using the angle each vector makes with the +*x* axis.

(*a*) Sketch the displacement vector (call it $\vec{A}$) and note that it makes an angle of 60° with the +*x* axis:



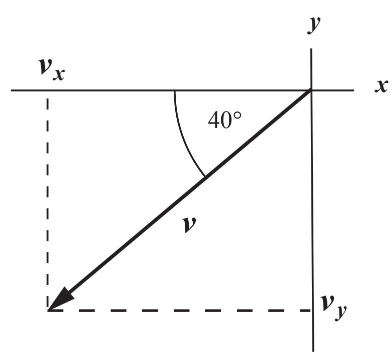
Find the *x* and *y* components of $\vec{A}$:

$$A_x = (10\text{ m})\cos 60° = \boxed{5.0\text{ m}}$$

and

$$A_y = (10\text{ m})\sin 60° = \boxed{8.7\text{ m}}$$

(*b*) Sketch the velocity vector (call it $\vec{v}$) and note that it makes an angle of 220° with the +*x* axis:



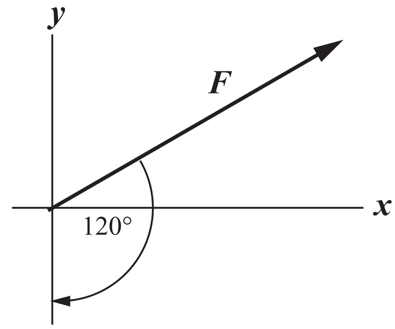
Find the *x* and *y* components of $\vec{v}$:

$$v_x = (25\text{ m/s})\cos 220° = \boxed{-19\text{ m/s}}$$

and

$$v_y = (25\text{ m/s})\sin 220° = \boxed{-16\text{ m/s}}$$

(c) Sketch the force vector (call it $\vec{F}$) and note that it makes an angle of 30° with the $+x$ axis:



Find the x and y components of $\vec{F}$:

$$F_x = (40\text{ lb})\cos 30° = \boxed{35\text{ lb}}$$

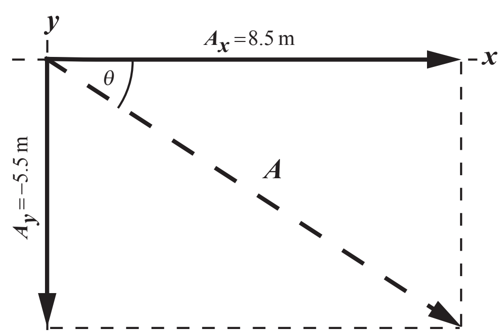
and

$$F_y = (40\text{ lb})\sin 30° = \boxed{20\text{ lb}}$$

54 • Rewrite the following vectors in terms of their magnitude and angle (counterclockwise from the $+x$ direction). (*a*) A displacement vector with an x component of +8.5 m and a y component of −5.5 m. (*b*) A velocity vector with an x component of −75 m/s and a y component of +35 m/s. (*c*) A force vector with a magnitude of 50 lb that is in the third quadrant with an x component whose magnitude is 40 lb.

Picture the Problem We can use the Pythagorean Theorem to find magnitudes of these vectors from their x and y components and trigonometry to find their direction angles.

(*a*) Sketch the components of the displacement vector (call it $\vec{A}$) and show their resultant:



Use the Pythagorean Theorem to find the magnitude of $\vec{A}$:

$$A = \sqrt{A_x^2 + A_y^2} = \sqrt{(8.5\text{ m})^2 + (-5.5\text{ m})^2}$$

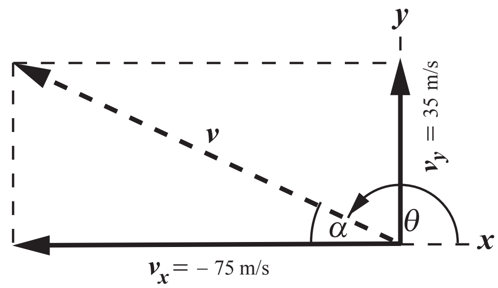
$$= \boxed{10\text{ m}}$$

Find the direction angle of $\vec{A}$:

$$\theta = \tan^{-1}\left(\frac{A_y}{A_x}\right) = \tan^{-1}\left(\frac{-5.5\text{ m}}{8.5\text{ m}}\right)$$

$$= \boxed{-33°} = \boxed{327°}$$

(b) Sketch the components of the velocity vector (call it $\vec{v}$) and show their resultant:



Use the Pythagorean Theorem to find the magnitude of $\vec{v}$ and trigonometry to find its direction angle:

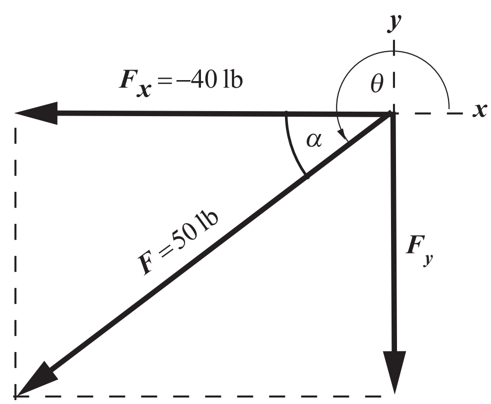
$$v = \sqrt{v_x^2 + v_y^2} = \sqrt{(-75\text{ m/s})^2 + (35\text{ m/s})^2}$$
$$= \boxed{83\text{ m/s}}$$

$$\alpha = \tan^{-1}\left(\frac{v_y}{v_x}\right) = \tan^{-1}\left(\frac{35\text{ m/s}}{75\text{ m/s}}\right) = 25°$$

and

$$\boldsymbol{\theta} = 180° - \boldsymbol{\alpha} = 180° - 25° = \boxed{155°}$$

(c) Sketch the force vector (call it $\vec{F}$) and its x-component and show F_y:



Use trigonometry to find α and, hence, θ:

$$\alpha = \cos^{-1}\left(\frac{F_x}{F}\right) = \cos^{-1}\left(\frac{40\text{ lb}}{50\text{ lb}}\right) = 37°$$

$$\theta = 180° + \alpha = 180° + 37° = \boxed{217°}$$

Use the relationship between a vector and its vertical component to find F_y:

$$F_y = F\sin\theta = (50\text{ lb})\sin 217°$$
$$= \boxed{-30\text{ lb}}$$

Remarks: In Part (*c*) we could have used the Pythagorean Theorem to find the magnitude of F_y.

55 • You walk 100 m in a straight line on a horizontal plane. If this walk took you 50 m east, what are your possible north or south movements? What are the possible angles that your walk made with respect to due east?

Picture the Problem There are two directions that you could have walked that are consistent with your having walked 50 m to the east. One possibility is walking in the north-east direction and the other is walking in the south-east direction. We can use the Pythagorean Theorem to find the distance you walked either north or south and then use trigonometry to find the two angles that correspond to your having walked in either of these directions.

Letting A represent the magnitude of your displacement on the walk, use the Pythagorean Theorem to relate A to its horizontal (A_x) and vertical (A_y) components:

$$A_y = \sqrt{A^2 - A_x^2}$$

Substitute numerical values and evaluate A_y:

$$A_y = \sqrt{(100\ \text{m})^2 - (50\ \text{m})^2} = \pm 87\ \text{m}$$

The plus-and-minus-signs mean that you could have gone 87 m north or 87 m south.

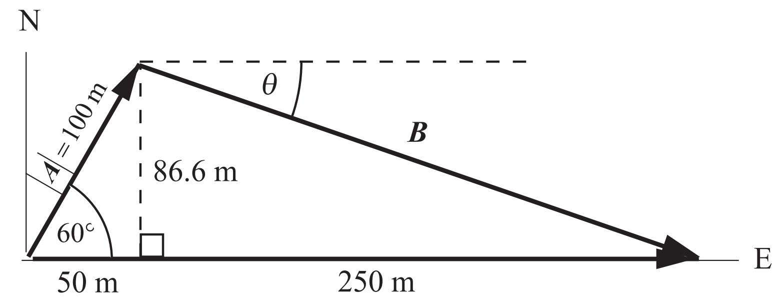
Use trigonometry to relate the directions you could have walked to the distance you walked and its easterly component:

$$\theta = \cos^{-1}\left(\frac{50\ \text{m}}{100\ \text{m}}\right) = \pm 60°$$

The plus-and-minus-signs mean that you could have walked 60° north of east or 60° south of east.

56 • The final destination of your journey is 300 m due east of your starting point. The first leg of this journey is the walk described in Problem 55, and the second leg is also a walk along a single straight-line path. Estimate graphically the length and heading for the second leg of your journey.

Picture the Problem Let $\vec{\boldsymbol{A}}$ be the vector whose length is 100 m and whose direction is 60° N of E. Let $\vec{\boldsymbol{B}}$ be the vector whose direction and magnitude we are to determine and assume that you initially walked in a direction north of east. The graphical representation that we can use to estimate these quantities is shown below. Knowing that the magnitude of $\vec{\boldsymbol{A}}$ is 100 m, use any convenient scale to determine the length of $\vec{\boldsymbol{B}}$ and a protractor to determine the value of θ.



The magnitude of the second leg of your journey is about 260 m at an angle of approximately 20° S of E. If you had initially walked into the southeast, the magnitude of the second leg of your journey would still be about 260 m but its direction would be approximately 20° N of E.

Remarks: If you use the Pythagorean Theorem and right-triangle trigonometry, you'll find that the length of the second leg of your journey is 265 m and that $\boldsymbol{\theta}$ = 19° S of E.

57 •• Given the following vectors: $\vec{\boldsymbol{A}} = 3.4\hat{\boldsymbol{i}} + 4.7\hat{\boldsymbol{j}}$, $\vec{\boldsymbol{B}} = (-7.7)\hat{\boldsymbol{i}} + 3.2\hat{\boldsymbol{j}}$, and $\vec{\boldsymbol{C}} = 5.4\hat{\boldsymbol{i}} + (-9.1)\hat{\boldsymbol{j}}$. (*a*) Find the vector $\vec{\boldsymbol{D}}$, in unit vector notation, such that $\vec{\boldsymbol{D}} + 2\vec{\boldsymbol{A}} - 3\vec{\boldsymbol{C}} + 4\vec{\boldsymbol{B}} = 0$. (*b*) Express your answer in Part (*a*) in terms of magnitude and angle with the +*x* direction.

Picture the Problem We can find the vector $\vec{\boldsymbol{D}}$ by solving the equation $\vec{\boldsymbol{D}} + 2\vec{\boldsymbol{A}} - 3\vec{\boldsymbol{C}} + 4\vec{\boldsymbol{B}} = 0$ for $\vec{\boldsymbol{D}}$ and then substituting for the vectors $\vec{\boldsymbol{A}}$, $\vec{\boldsymbol{B}}$ and $\vec{\boldsymbol{C}}$. In (*b*) we can use the components of $\vec{\boldsymbol{D}}$ to find its magnitude and direction.

(*a*) Solve the vector equation that gives the condition that must satisfied for $\vec{\boldsymbol{D}}$:

$$\vec{\boldsymbol{D}} = -2\vec{\boldsymbol{A}} + 3\vec{\boldsymbol{C}} - 4\vec{\boldsymbol{B}}$$

Substitute for $\vec{\boldsymbol{A}}, \vec{\boldsymbol{C}}$ and $\vec{\boldsymbol{B}}$ and simplify to obtain:

$$\begin{aligned}\vec{\boldsymbol{D}} &= -2\left(3.4\hat{\boldsymbol{i}} + 4.7\hat{\boldsymbol{j}}\right) + 3\left(5.4\hat{\boldsymbol{i}} - 9.1\hat{\boldsymbol{j}}\right) - 4\left(-7.7\hat{\boldsymbol{i}} + 3.2\hat{\boldsymbol{j}}\right)\\ &= (-6.8 + 16.2 + 30.8)\hat{\boldsymbol{i}} + (-9.4 - 27.3 - 12.8)\hat{\boldsymbol{j}}\\ &= 40.2\hat{\boldsymbol{i}} - 49.5\hat{\boldsymbol{j}} = \boxed{40\hat{\boldsymbol{i}} - 50\hat{\boldsymbol{j}}}\end{aligned}$$

(*b*) Use the Pythagorean Theorem to relate the magnitude of $\vec{\boldsymbol{D}}$ to its components D_x and D_y:

$$D = \sqrt{D_x^2 + D_y^2}$$

Substitute numerical values and evaluate D:

$$D = \sqrt{(40.2)^2 + (-49.5)^2} = \boxed{63.8}$$

Use trigonometry to express and evaluate the angle θ :

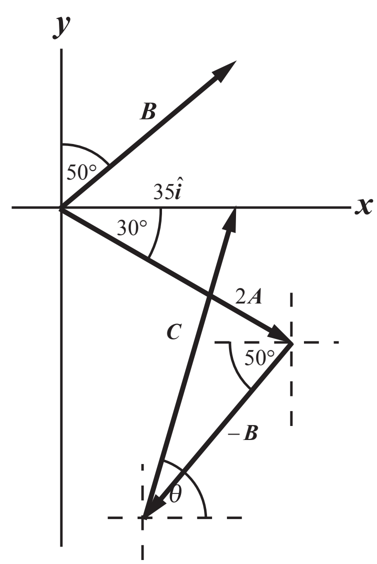
$$\theta = \tan^{-1}\left(\frac{D_y}{D_x}\right) = \tan^{-1}\left(\frac{-49.5}{40.2}\right)$$
$$= \boxed{-51°}$$

where the minus sign means that $\vec{D}$ is in the 4th quadrant.

58 •• Given the following force vectors: $\vec{A}$ is 25 lb at an angle of 30° clockwise from the +*x* axis, and $\vec{B}$ is 42 lb at an angle of 50° clockwise from the +*y* axis. (*a*) Make a sketch and visually estimate the magnitude and angle of the vector $\vec{C}$ such that $2\vec{A} + \vec{C} - \vec{B}$ results in a vector with a magnitude of 35 lb pointing in the +*x* direction. (*b*) Repeat the calculation in Part (*a*) using the method of components and compare your result to the estimate in (*a*).

Picture the Problem A diagram showing the condition that $2\vec{A} + \vec{C} - \vec{B} = 35\hat{\boldsymbol{i}}$ and from which one can scale the values of C and θ is shown below. In (*b*) we can use the two scalar equations corresponding to this vector equation to check our graphical results.

(*a*) A diagram showing the conditions imposed by $2\vec{A} + \vec{C} - \vec{B} = 35\hat{\boldsymbol{i}}$ approximately to scale is shown to the right.



The magnitude of $\vec{C}$ is approximately $\boxed{57\text{ lb}}$ and the angle θ is approximately $\boxed{68°.}$

(*b*) Express the condition relating the vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$:

$$2\vec{A} + \vec{C} - \vec{B} = 35\hat{\boldsymbol{i}}$$

The corresponding scalar equations are:

$$2A_x + C_x - B_x = 35$$
and
$$2A_y + C_y - B_y = 0$$

Solve these equations for C_x and C_y to obtain:

$$C_x = 35 - 2A_x + B_x$$
and
$$C_y = -2A_y + B_y$$

Substitute for the x and y components of $\vec{A}$ and $\vec{B}$ to obtain:

$$\begin{aligned} C_x &= 35\text{ lb} - 2[(25\text{ lb})\cos 330°] \\ &\qquad + (42\text{ lb})\cos 40° \\ &= 23.9\text{ lb} \end{aligned}$$
and
$$\begin{aligned} C_y &= -2[(25\text{ lb})\sin 330°] + (42\text{ lb})\sin 40° \\ &= 52\text{ lb} \end{aligned}$$

Use the Pythagorean Theorem to relate the magnitude of $\vec{C}$ to its components:

$$C = \sqrt{C_x^2 + C_y^2}$$

Substitute numerical values and evaluate C:

$$C = \sqrt{(23.9\text{ lb})^2 + (52.0\text{ lb})^2} = \boxed{57\text{ lb}}$$

Use trigonometry to find the direction of $\vec{C}$:

$$\theta = \tan^{-1}\left(\frac{C_y}{C_x}\right) = \tan^{-1}\left(\frac{52.0\text{ lb}}{23.9\text{ lb}}\right) = \boxed{65°}$$

Remarks: The analytical results for *C* and θ are in excellent agreement with the values determined graphically.

59 •• [SSM] Calculate the unit vector (in terms of $\hat{\boldsymbol{i}}$ and $\hat{\boldsymbol{j}}$) in the direction opposite to the direction of each of the vectors in Problem 57.

Picture the Problem The unit vector in the direction opposite to the direction of a vector is found by taking the negative of the unit vector in the direction of the vector. The unit vector in the direction of a given vector is found by dividing the given vector by its magnitude.

The unit vector in the direction of $\vec{A}$ is given by:

$$\hat{\boldsymbol{A}} = \frac{\vec{A}}{|\vec{A}|} = \frac{\vec{A}}{\sqrt{A_x^2 + A_y^2}}$$

Substitute for $\vec{A}$, A_x, and A_y and evaluate $\hat{\boldsymbol{A}}$:

$$\hat{\boldsymbol{A}} = \frac{3.4\hat{\boldsymbol{i}} + 4.7\hat{\boldsymbol{j}}}{\sqrt{(3.4)^2 + (4.7)^2}} = 0.59\hat{\boldsymbol{i}} + 0.81\hat{\boldsymbol{j}}$$

The unit vector in the direction opposite to that of $\vec{A}$ is given by:

$$-\hat{A} = \boxed{-0.59\hat{i} - 0.81\hat{j}}$$

The unit vector in the direction of $\vec{B}$ is given by:

$$\hat{B} = \frac{\vec{B}}{|\vec{B}|} = \frac{\vec{B}}{\sqrt{B_x^2 + B_y^2}}$$

Substitute for $\vec{B}$, B_x, and B_y and evaluate $\hat{B}$:

$$\hat{B} = \frac{-7.7\hat{i} + 3.2\hat{j}}{\sqrt{(-7.7)^2 + (3.2)^2}} = -0.92\hat{i} + 0.38\hat{j}$$

The unit vector in the direction opposite to that of $\vec{B}$ is given by:

$$-\hat{B} = \boxed{0.92\hat{i} - 0.38\hat{j}}$$

The unit vector in the direction of $\vec{C}$ is given by:

$$\hat{C} = \frac{\vec{C}}{|\vec{C}|} = \frac{\vec{C}}{\sqrt{C_x^2 + C_y^2}}$$

Substitute for $\vec{C}$, C_x, and C_y and evaluate $\hat{C}$:

$$\hat{C} = \frac{5.4\hat{i} - 9.1\hat{j}}{\sqrt{(5.4)^2 + (-9.1)^2}} = \boxed{0.51\hat{i} - 0.86\hat{j}}$$

The unit vector in the direction opposite that of $\vec{C}$ is given by:

$$-\hat{C} = \boxed{-0.51\hat{i} + 0.86\hat{j}}$$

60 •• Unit vectors $\hat{i}$ and $\hat{j}$ are directed east and north, respectively. Calculate the unit vector (in terms of $\hat{i}$ and $\hat{j}$) in the following directions. (*a*) northeast, (*b*) 70° clockwise from the $-y$ axis, (*c*) southwest.

Picture the Problem The unit vector in a given direction is a vector pointing in that direction whose magnitude is 1.

(*a*) The unit vector in the northeast direction is given by:

$$\hat{u}_{\text{NE}} = (1)\cos 45°\hat{i} + (1)\sin 45°\hat{j} = \boxed{0.707\hat{i} + 0.707\hat{j}}$$

(*b*) The unit vector 70° clockwise from the $-y$ axis is given by:

$$\hat{u} = (1)\cos 200°\hat{i} + (1)\sin 200°\hat{j} = \boxed{-0.940\hat{i} - 0.342\hat{j}}$$

(*c*) The unit vector in the southwest direction is given by:

$$\hat{\boldsymbol{u}}_{\mathrm{SW}} = (1)\cos 225°\hat{\boldsymbol{i}} + (1)\sin 225°\hat{\boldsymbol{j}}$$
$$= \boxed{-0.707\hat{\boldsymbol{i}} - 0.707\hat{\boldsymbol{j}}}$$

Remarks: One can confirm that a given vector is, in fact, a unit vector by checking its magnitude.

General Problems

61 • [SSM] The Apollo trips to the moon in the 1960's and 1970's typically took 3 days to travel the Earth-moon distance once they left Earth orbit. Estimate the spacecraft's average speed in kilometers per hour, miles per hour, and meters per second.

Picture the Problem Average speed is defined to be the distance traveled divided by the elapsed time. The Earth-moon distance and the distance and time conversion factors can be found on the inside-front cover of the text. We'll assume that 3 days means exactly three days.

Express the average speed of Apollo as it travels to the moon:

$$v_{\mathrm{av}} = \frac{\text{distance traveled}}{\text{elapsed time}}$$

Substitute numerical values to obtain:

$$v_{\mathrm{av}} = \frac{2.39\times10^{5}\ \mathrm{mi}}{3\ \mathrm{d}}$$

Use the fact that there are 24 h in 1 d to convert 3 d into hours:

$$v_{\mathrm{av}} = \frac{2.39\times10^{5}\ \mathrm{mi}}{3\ \mathrm{d}\times\dfrac{24\ \mathrm{h}}{\mathrm{d}}}$$
$$= 3.319\times10^{3}\ \mathrm{mi/h}$$
$$= \boxed{3.32\times10^{3}\ \mathrm{mi/h}}$$

Use the fact that 1 mi is equal to 1.609 km to convert the spacecraft's average speed to km/h:

$$v_{\mathrm{av}} = 3.319\times10^{3}\ \frac{\mathrm{mi}}{\mathrm{h}}\times1.609\,\frac{\mathrm{km}}{\mathrm{mi}} = 5.340\times10^{3}\ \frac{\mathrm{km}}{\mathrm{h}} = \boxed{5.34\times10^{3}\ \mathrm{km/h}}$$

Use the facts that there are 3600 s in 1 h and 1000 m in 1 km to convert the spacecraft's average speed to m/s:

$$v_{\text{av}} = 5.340\times10^{6}\,\frac{\text{km}}{\text{h}}\times\frac{10^{3}\text{ m}}{\text{km}}\times\frac{1\text{ h}}{3600\text{ s}} = 1.485\times10^{3}\text{ m/s} = \boxed{1.49\times10^{3}\text{ m/s}}$$

Remarks: An alternative to multiplying by 10^3 m/km in the last step is to replace the metric prefix ″k″ in ″km″by 10^3.

62 • On many of the roads in Canada the speed limit is 100 km/h. What is this speed limit in miles per hour?

Picture the Problem We can use the conversion factor 1 mi = 1.609 km to convert 100 km/h into mi/h.

Multiply 100 km/h by 1 mi/1.609 km to obtain:

$$100\,\frac{\text{km}}{\text{h}} = 100\,\frac{\text{km}}{\text{h}}\times\frac{1\,\text{mi}}{1.609\,\text{km}}$$
$$= \boxed{62.2\,\text{mi/h}}$$

63 • If you could count \$1.00 per second, how many years would it take to count 1.00 billion dollars?

Picture the Problem We can use a series of conversion factors to convert 1 billion seconds into years.

Multiply 1 billion seconds by the appropriate conversion factors to convert into years:

$$10^{9}\text{ s} = 10^{9}\text{ s}\times\frac{1\text{h}}{3600\text{s}}\times\frac{1\,\text{day}}{24\,\text{h}}\times\frac{1\,\text{y}}{365.24\,\text{days}} = \boxed{31.7\,\text{y}}$$

64 • (*a*) The speed of light in vacuum is 186,000 mi/s = 3.00×10^8 m/s. Use this fact to find the number of kilometers in a mile. (*b*) The weight of 1.00 ft^3 of water is 62.4 lb, and 1.00 ft = 30.5 cm. Use this and the fact that 1.00 cm^3 of water has a mass of 1.00 g to find the weight in pounds of a 1.00-kg mass.

Picture the Problem In both the examples cited we can equate expressions for the physical quantities, expressed in different units, and then divide both sides of the equation by one of the expressions to obtain the desired conversion factor.

(*a*) Divide both sides of the equation expressing the speed of light in the two systems of measurement by 186,000 mi/s to obtain:

$$1 = \frac{3.00\times10^{8}\ \text{m/s}}{1.86\times10^{5}\ \text{mi/h}} = 1.61\times10^{3}\ \text{m/mi}$$
$$= \left(1.61\times10^{3}\ \frac{\text{m}}{\text{mi}}\right)\left(\frac{1\,\text{km}}{10^{3}\ \text{m}}\right)$$
$$= \boxed{1.61\,\text{km/mi}}$$

(*b*) Find the volume of 1.00 kg of water:

Volume of 1.00 kg = 10^3 g is 10^3 cm^3

Express 10^3 cm^3 in ft^3:

$$(10\,\text{cm})^3\left(\frac{1.00\,\text{ft}}{30.5\ \text{cm}}\right)^3 = 0.03525\,\text{ft}^3$$

Relate the weight of 1.00 ft^3 of water to the volume occupied by 1.00 kg of water:

$$\frac{1.00\,\text{kg}}{0.03525\,\text{ft}^3} = 62.4\frac{\text{lb}}{\text{ft}^3}$$

Divide both sides of the equation by the left-hand side to obtain:

$$1 = \frac{62.4\dfrac{\text{lb}}{\text{ft}^3}}{\dfrac{1.00\,\text{kg}}{0.03525\,\text{ft}^3}} = \boxed{2.20\,\text{lb/kg}}$$

65 • The mass of one uranium atom is 4.0×10^{-26} kg. How many uranium atoms are there in 8.0 g of pure uranium?

Picture the Problem We can use the given information to equate the ratios of the number of uranium atoms in 8 g of pure uranium and of 1 atom to its mass.

Express the proportion relating the number of uranium atoms N_U in 8.0 g of pure uranium to the mass of 1 atom:

$$\frac{N_U}{8.0\,\text{g}} = \frac{1\,\text{atom}}{4.0\times10^{-26}\ \text{kg}}$$

Solve for and evaluate N_U:

$$N_U = \left(8.0\,\text{g}\times\frac{1\,\text{kg}}{10^3\ \text{g}}\right)\left(\frac{1\,\text{atom}}{4.0\times10^{-26}\ \text{kg}}\right)$$
$$= \boxed{2.0\times10^{23}}$$

66 •• During a thunderstorm, a total of 1.4 in of rain falls. How much water falls on one acre of land? (1 mi^2 = 640 acres.) Express your answer in (*a*) cubic inches, (*b*) cubic feet, (*c*) cubic meters, and (*d*) kilograms. Note that the density of water is 1000 kg/m^3.

Picture the Problem Assuming that the water is distributed uniformly over the one acre of land, its volume is the product of the area over which it is distributed and its depth. The mass of the water is the product of its density and volume. The required conversion factors can be found in the front material of the text.

(*a*) Express the volume V of water in terms of its depth h and the area A over which it falls:

$$V = Ah$$

Substitute numerical values and evaluate V:

$$V = (1\,\text{acre})\left(\frac{1\,\text{mi}^2}{640\,\text{acres}}\right)\left(\frac{5280\,\text{ft}}{\text{mi}}\right)^2\left(\frac{12\,\text{in}}{\text{ft}}\right)^2(1.4\,\text{in}) = 8.782\times10^6\,\text{in}^3$$

$$= \boxed{8.8\times10^6\,\text{in}^3}$$

(*b*) Convert in^3 into ft^3:

$$V = 8.782\times10^6\,\text{in}^3\times\left(\frac{1\,\text{ft}}{12\,\text{in}}\right)^3$$

$$= 5.082\times10^3\,\text{ft}^3 = \boxed{5.1\times10^3\,\text{ft}^3}$$

(*c*) Convert ft^3 into m^3:

$$V = 5.082\times10^3\,\text{ft}^3\times\left(\frac{12\,\text{in}}{\text{ft}}\right)^3\times\left(\frac{2.540\,\text{cm}}{\text{in}}\right)^3\times\left(\frac{1\,\text{m}}{100\,\text{cm}}\right)^3 = 1.439\times102\,\text{m}^3$$

$$= \boxed{1.4\times10^2\,\text{m}^3}$$

(*d*) The mass of the water is the product of its density ρ and volume V:

$$m = \rho V$$

Substitute numerical values and evaluate m:

$$m = \left(10^3\,\frac{\text{kg}}{\text{m}^3}\right)(1.439\times10^2\,\text{m}^3)$$

$$= \boxed{1.4\times10^5\,\text{kg}}$$

67 •• An iron nucleus has a radius of 5.4×10^{-15} m and a mass of 9.3×10^{-26} kg. (*a*) What is its mass per unit volume in kg/ m^3? (*b*) If Earth had the same mass per unit volume, what would be its radius? (The mass of Earth is 5.98×10^{24} kg.)

Picture the Problem The mass per unit volume of an object is its density.

(*a*) The density ρ of an object is its mass m per unit volume V:

$$\rho = \frac{m}{V}$$

Assuming the iron nucleus to be spherical, its volume as a function of its radius r is given by:

$$V = \frac{4}{3}\pi r^3$$

Substitute for V and simplify to obtain:

$$\rho = \frac{m}{\frac{4}{3}\pi r^3} = \frac{3m}{4\pi r^3} \qquad (1)$$

Substitute numerical values and evaluate ρ:

$$\rho = \frac{3\left(9.3\times10^{-26}\ \text{kg}\right)}{4\pi\left(5.4\times10^{-15}\ \text{m}\right)^3} = 1.410\times10^{17}\ \text{kg/m}^3 = \boxed{1.4\times10^{17}\ \text{kg/m}^3}$$

(*b*) Solve equation (1) for r to obtain:

$$r = \sqrt[3]{\frac{3m}{4\pi\rho}}$$

Substitute numerical values and evaluate r:

$$r = \sqrt[3]{\frac{3\left(5.98\times10^{24}\ \text{kg}\right)}{4\pi\left(1.410\times10^{17}\ \frac{\text{kg}}{\text{m}^3}\right)}} = \boxed{2.2\times10^{2}\ \text{m}}$$

or about 200 m!

68 •• The Canadian Norman Wells Oil Pipeline extends from Norman Wells, Northwest Territories, to Zama, Alberta. The 8.68×10^5-m-long pipeline has an inside diameter of 12 in and can be supplied with oil at 35 L/s. (*a*) What is the volume of oil in the pipeline if it is full at some instant in time? (*b*) How long would it take to fill the pipeline with oil if it is initially empty?

Picture the Problem The volume of a cylinder is the product of its cross-sectional area and its length. The time required to fill the pipeline with oil is the ratio of its volume to the flow rate R of the oil. We'll assume that the pipe has a diameter of exactly 12 in.

(*a*) Express the volume V of the cylindrical pipe in terms of its radius r and its length L:

$$V = \pi r^2 L$$

Substitute numerical values and evaluate V:

$$V = \pi\left(6\,\text{in} \times \frac{2.540\times10^{-2}\,\text{m}}{\text{in}}\right)^2 \left(8.68\times10^5\ \text{m}\right) = \boxed{6.3\times10^4\ \text{m}^3}$$

(*b*) Express the time Δt to fill the pipe in terms of its volume V and the flow rate R of the oil:

$$\Delta t = \frac{V}{R}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{6.3\times10^4\ \text{m}^3}{\left(35\,\frac{\text{L}}{\text{s}}\right)\left(\frac{10^{-3}\ \text{m}^3}{\text{L}}\right)} = \boxed{1.8\times10^6\ \text{s}}$$

or about 21 days!

69 •• The astronomical unit (AU) is defined as the mean center-to-center distance from Earth to the sun, namely 1.496×10^{11} m. The parsec is the radius of a circle for which a central angle of 1 s intercepts an arc of length 1 AU. The light-year is the distance that light travels in 1 y. (*a*) How many parsecs are there in one astronomical unit? (*b*) How many meters are in a parsec? (*c*) How many meters in a light-year? (*d*) How many astronomical units in a light-year? (*e*) How many light-years in a parsec?

Picture the Problem We can use the relationship between an angle θ, measured in radians, subtended at the center of a circle, the radius R of the circle, and the length L of the arc to answer these questions concerning the astronomical units of measure. We'll take the speed of light to be 2.998×10^8 m/s.

(*a*) Relate the angle θ subtended by an arc of length S to the distance R:

$$\theta = \frac{S}{R} \Rightarrow S = R\theta \qquad (1)$$

Substitute numerical values and evaluate S:

$$S = (1\,\text{parsec})(1\,\text{s})\left(\frac{1\,\text{min}}{60\,\text{s}}\right)\left(\frac{1°}{60\,\text{min}}\right)\left(\frac{2\pi\,\text{rad}}{360°}\right) = \boxed{4.848\times 10^{-6}\,\text{parsec}}$$

(b) Solving equation (1) for R yields:

$$R = \frac{S}{\theta}$$

Substitute numerical values and evaluate R:

$$R = \frac{1.496\times 10^{11}\,\text{m}}{(1\,\text{s})\left(\frac{1\,\text{min}}{60\,\text{s}}\right)\left(\frac{1°}{60\,\text{min}}\right)\left(\frac{2\pi\,\text{rad}}{360°}\right)} = \boxed{3.086\times 10^{16}\,\text{m}}$$

(c) The distance D light travels in a given interval of time Δt is given by:

$$D = c\Delta t$$

Substitute numerical values and evaluate D:

$$D = \left(2.998\times 10^{8}\,\frac{\text{m}}{\text{s}}\right)\left(365.24\frac{\text{d}}{\text{y}}\right)\left(24\frac{\text{h}}{\text{d}}\right)\left(60\frac{\text{min}}{\text{h}}\right)\left(60\frac{\text{s}}{\text{min}}\right) = \boxed{9.461\times 10^{15}\,\text{m}}$$

(d) Use the definition of 1 AU and the result from Part (c) to obtain:

$$1\,c\cdot\text{y} = \left(9.461\times 10^{15}\,\text{m}\right)\left(\frac{1\,\text{AU}}{1.496\times 10^{11}\,\text{m}}\right) = \boxed{6.324\times 10^{4}\,\text{AU}}$$

(e) Combine the results of Parts (b) and (c) to obtain:

$$1\,\text{parsec} = \left(3.086\times 10^{16}\,\text{m}\right)\left(\frac{1\,c\cdot\text{y}}{9.461\times 10^{15}\,\text{m}}\right) = \boxed{3.262\,c\cdot\text{y}}$$

70 •• If the average density of the universe is at least 6×10^{-27} kg/m^3, then the universe will eventually stop expanding and begin contracting. (a) How many electrons are needed in each cubic meter to produce the critical density? (b) How many protons per cubic meter would produce the critical density? ($m_e = 9.11 \times 10^{-31}$ kg; $m_p = 1.67 \times 10^{-27}$ kg.)

Picture the Problem Let N_e and N_p represent the number of electrons and the number of protons, respectively and ρ the critical average density of the universe. We can relate these quantities to the masses of the electron and proton using the definition of density.

(*a*) Using its definition, relate the required density ρ to the electron density N_e/V:

$$\rho = \frac{m}{V} = \frac{N_e m_e}{V} \Rightarrow \frac{N_e}{V} = \frac{\rho}{m_e} \quad (1)$$

Substitute numerical values and evaluate N_e/V:

$$\frac{N_e}{V} = \frac{6\times10^{-27}\ \text{kg/m}^3}{9.11\times10^{-31}\ \text{kg/electron}} = 6.586\times10^3\ \text{electrons/m}^3 \approx \boxed{7\times10^3\ \text{electrons/m}^3}$$

(*b*) Express and evaluate the ratio of the masses of an electron and a proton:

$$\frac{m_e}{m_p} = \frac{9.11\times10^{-31}\ \text{kg}}{1.67\times10^{-27}\ \text{kg}} = 5.455\times10^{-4}$$

Rewrite equation (1) in terms of protons:

$$\frac{N_p}{V} = \frac{\rho}{m_p} \quad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{\frac{N_p}{V}}{\frac{N_e}{V}} = \frac{m_e}{m_p} \text{ or } \frac{N_p}{V} = \frac{m_e}{m_p}\left(\frac{N_e}{V}\right)$$

Substitute numerical values and use the result from Part (*a*) to evaluate N_p/V:

$$\frac{N_p}{V} = \left(5.455\times10^{-4}\right)\left(6.586\times10^3\ \text{electrons/m}^3\right) \approx \boxed{4\,\text{protons/m}^3}$$

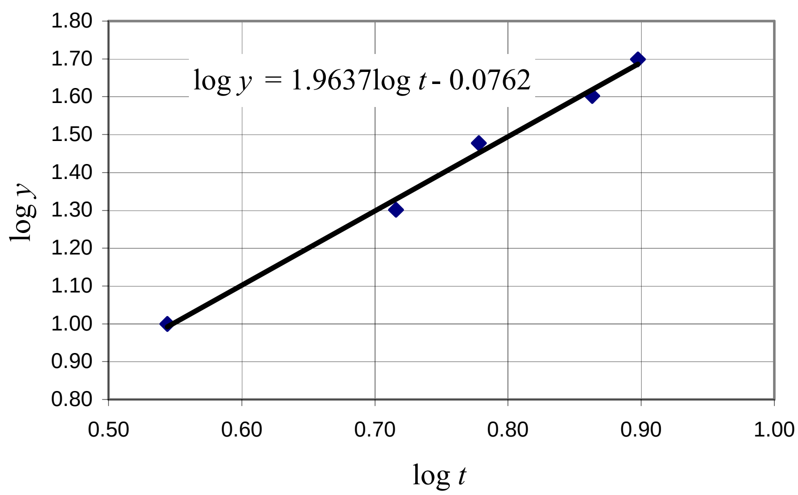
71 ••• You are an astronaut doing physics experiments on the moon. You are interested in the experimental relationship between distance fallen, y, and time elapsed, t, of falling objects dropped from rest. You have taken some data for a falling penny, which is represented in the table below. You expect that a general relationship between distance y and time t is $y = Bt^C$, where B and C are constants to be determined experimentally. To accomplish this, create a *log-log* plot of the data: (*a*) graph log(y) vs. log(t), with log(y) the ordinate variable and log(t) the abscissa variable. (*b*) Show that if you take the log of each side of your equation, you get log(y) = log(B) + Clog(t). (*c*) By comparing this linear relationship to the graph of the data, estimate the values of B and C. (*d*) If you

drop a penny, how long should it take to fall 1.0 m? (*e*) In the next chapter, we will show that the expected relationship between y and t is $y = \frac{1}{2}at^2$, where a is the acceleration of the object. What is the acceleration of objects dropped on the moon?

y (m)	10	20	30	40	50
t (s)	3.5	5.2	6.0	7.3	7.9

Picture the Problem We can plot log y versus log t and find the slope of the best-fit line to determine the exponent C. The value of B can be determined from the intercept of this graph. Once we know C and B, we can solve $y = Bt^C$ for t as a function of y and use this result to determine the time required for an object to fall a given distance on the surface of the moon.

(*a*) The following graph of log y versus log t was created using a spreadsheet program. The equation shown on the graph was obtained using Excel's ″Add Trendline″ function. (Excel's ″Add Trendline″ function uses regression analysis to generate the trendline.)



(*b*) Taking the logarithm of both sides of the equation $y = Bt^C$ yields:

$$\log y = \log\left(Bt^C\right) = \log B + \log t^C$$
$$= \boxed{\log B + C\log t}$$

(*c*) Note that this result is of the form:

$$Y = b + mX$$
where
$Y = \log y$, $b = \log B$, $m = C$, and
$X = \log t$

From the regression analysis (trendline) we have: log B = −0.076

Solving for B yields: $B = 10^{-0.076} = \boxed{0.84\ \text{m/s}^2}$

where we have inferred the units from th given for $y = Bt^C$.

Also, from the regression analysis we have: $C = 1.96 \approx \boxed{2.0}$

(d) Solve $y = Bt^C$ for t to obtain:

$$t = \left(\frac{y}{B}\right)^{\frac{1}{C}}$$

Substitute numerical values and evaluate t to determine how long it would take a penny to fall 1.0 m:

$$t = \left(\frac{1.0\ \text{m}}{0.84\ \dfrac{\text{m}}{\text{s}^2}}\right)^{\frac{1}{2}} \approx \boxed{1.1\ \text{s}}$$

(*e*) Substituting for *B* and *C* in $y = Bt^C$ yields:

$$y = \left(0.84\ \frac{\text{m}}{\text{s}^2}\right)t^2$$

Compare this equation to $y = \frac{1}{2}at^2$ to obtain:

$$\tfrac{1}{2}a = 0.84\ \frac{\text{m}}{\text{s}^2}$$

and

$$a = 2\left(0.84\ \frac{\text{m}}{\text{s}^2}\right) = \boxed{1.7\ \frac{\text{m}}{\text{s}^2}}$$

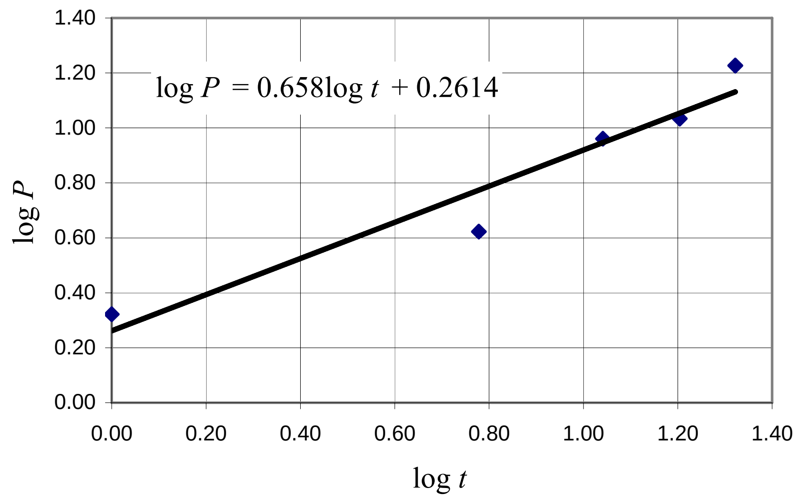
Remarks: One could use a graphing calculator to obtain the results in Parts (*a*) and (*c*).

72 **•••** A particular company's stock prices vary with the market and with the company's type of business, and can be very unpredictable, but people often try to look for mathematical patterns where they may not belong. Corning is a materials-engineering company located in upstate New York. Below is a table of the price of Corning stock on August 3, for every 5 years from 1981 to 2001. Assume that the price follows a power law: price (in \$) = Bt^C where *t* is expressed in years. (*a*) Evaluate the constants *B* and *C*. (*b*) According to the power law, what should the price of Corning stock have been on August 3, 2000? (It was actually \$82.83!)

Price (dollars)	2.10	4.19	9.14	10.82	16.85
Years since 1980	1	6	11	16	21

Picture the Problem We can plot log P versus log t and find the slope of the best-fit line to determine the exponent C. The value of B can be determined from the intercept of this graph. Once we know C and B, we can use $P = Bt^C$ to predict the price of Corning stock as a function of time.

(*a*) The following graph of log P versus log was created using a spreadsheet program. The equation shown on the graph was obtained using Excel's ″Add Trendline″ function. (Excel's ″Add Trendline″ function uses regression analysis to generate the trendline.)



Taking the logarithm of both sides of the equation $P = Bt^C$ yields:

$$\log P = \log\left(Bt^C\right) = \log B + \log t^C$$
$$= \log B + C\log t$$

Note that this result is of the form:

$Y = b + mX$
where
$Y = \log P$, $b = \log B$, $m = C$, and
$X = \log t$

From the regression analysis (trendline) we have:

$$\log B = 0.2614 \Rightarrow B = 10^{0.2614} = \boxed{\$1.83}$$

Also, from the regression analysis we have:

$$C = \boxed{0.658}$$

(*b*) Substituting for B and C in $P = Bt^C$ yields:

$$P = (\$1.83)t^{0.658}$$

Evaluate $P(20\text{ y})$ to obtain: $P(20\text{ y}) = (\$1.83)(20)^{0.658} = \boxed{\$13.14}$

Remarks: One could use a graphing calculator to obtain these results.

73 ••• [SSM] The Super-Kamiokande neutrino detector in Japan is a large transparent cylinder filled with ultra pure water. The height of the cylinder is 41.4 m and the diameter is 39.3 m. Calculate the mass of the water in the cylinder. Does this match the claim posted on the official Super-K Web site that the detector uses 50000 tons of water?

Picture the Problem We can use the definition of density to relate the mass of the water in the cylinder to its volume and the formula for the volume of a cylinder to express the volume of water used in the detector's cylinder. To convert our answer in kg to lb, we can use the fact that 1 kg weighs about 2.205 lb.

Relate the mass of water contained in the cylinder to its density and volume:

$$m = \rho V$$

Express the volume of a cylinder in terms of its diameter d and height h:

$$V = A_{\text{base}}h = \frac{\pi}{4}d^2h$$

Substitute in the expression for m to obtain:

$$m = \rho\frac{\pi}{4}d^2h$$

Substitute numerical values and evaluate m:

$$m = \left(10^3\text{ kg/m}^3\right)\left(\frac{\pi}{4}\right)(39.3\,\text{m})^2(41.4\,\text{m}) = 5.022\times10^7\text{ kg}$$

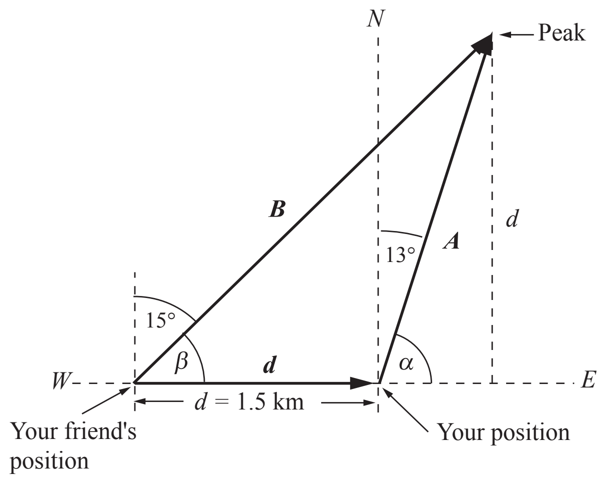
Convert 5.02×10^7 kg to tons:

$$m = 5.022\times10^7\text{ kg}\times\frac{2.205\,\text{lb}}{\text{kg}}\times\frac{1\,\text{ton}}{2000\,\text{lb}} = 55.4\times10^3\text{ ton}$$

The 50,000-ton claim is conservative. The actual weight is closer to 55,000 tons.

74 ••• You and a friend are out hiking across a large flat plain and decide to determine the height of a distant mountain peak, and also the horizontal distance from you to the peak Figure 1-19). In order to do this, you stand in one spot and determine that the sightline to the top of the peak is inclined at 7.5° above the horizontal. You also make note of the heading to the peak at that point: 13° east of north. You stand at the original position, and your friend hikes due west for 1.5 km. He then sights the peak and determines that its sightline has a heading of 15° east of north. How far is the mountain from your position, and how high is its summit above your position?

Picture the Problem Vector $\vec{A}$ lies in the plane of the plain and locates the base or the peak relative to you. Vector $\vec{B}$ also lies in the plane of the plain and locates the base of the peak relative to your friend when he/she has walked 1.5 km to the west. We can use the geometry of the diagram and the *E-W* components of the vectors $\vec{d}$, $\vec{B}$ and $\vec{A}$ to find the distance to the mountain from your position. Once we know the distance *A*, we can use a trigonometric relationship to find the height of the peak above your position.



Referring to the diagram, note that:

$$B\sin\beta = h$$
and
$$A\sin\alpha = h$$

Equating these expressions for *h* gives:

$$B\sin\beta = A\sin\alpha \Rightarrow B = \frac{\sin\alpha}{\sin\beta}A$$

Adding the *E-W* components of the vectors $\vec{d}$, $\vec{B}$ and $\vec{A}$ yields:

$$1.5\text{ km} = B\cos\beta - A\cos\alpha$$

Substitute for *B* and simplify to obtain:

$$1.5\text{ km} = A\frac{\sin\alpha}{\sin\beta}\cos\beta - A\cos\alpha$$
$$= A\left(\frac{\sin\alpha}{\tan\beta} - \cos\alpha\right)$$

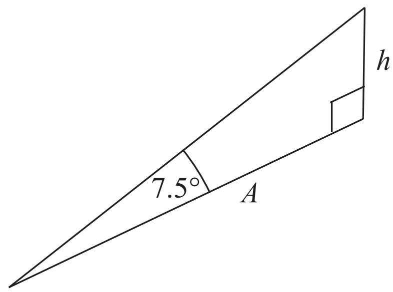
Solving for *A* yields:

$$A = \frac{1.5\text{ km}}{\dfrac{\sin\alpha}{\tan\beta} - \cos\alpha}$$

Substitute numerical values and evaluate A:

$$A = \frac{1.5\text{ km}}{\dfrac{\sin 77°}{\tan 75°} - \cos 77°} = 41.52\text{ km}$$
$$= \boxed{42\text{ km}}$$

Referring to the following diagram, we note that:



$$h = A\tan 7.5°$$
$$= (41.52\text{ km})\tan 7.5°$$
$$= \boxed{5.5\text{ km}}$$

Remarks: One can also solve this problem using the law of sines.

75 ••• The table below gives the periods T and orbit radii r for the motions of four satellites orbiting a dense, heavy asteroid. (a) These data can be fitted by the formula $T = Cr^n$. Find the values of the constants C and n. (b) A fifth satellite is discovered to have a period of 6.20 y. Find the radius for the orbit of this satellite, which fits the same formula.

Period T, y	0.44	1.61	3.88	7.89
Radius r, Gm	0.088	0.208	0.374	0.600

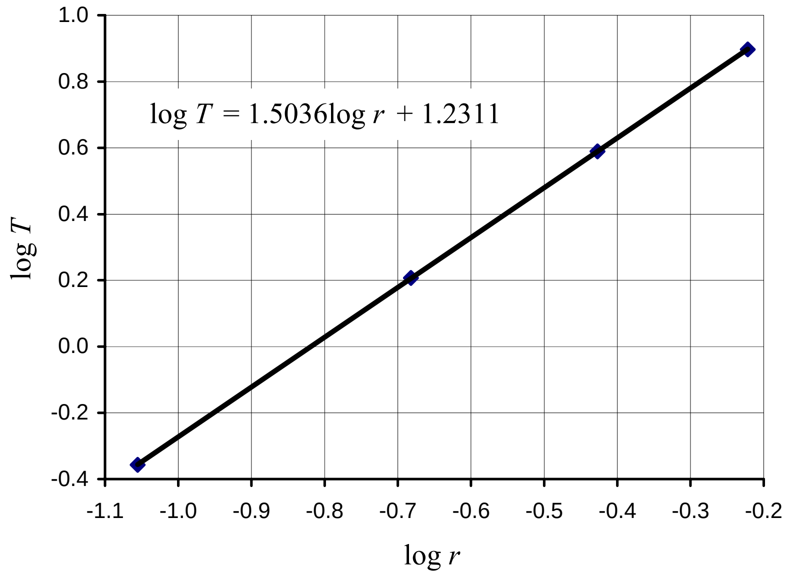
Picture the Problem We can plot log T versus log r and find the slope of the best-fit line to determine the exponent n. We can then use any of the ordered pairs to evaluate C. Once we know n and C, we can solve $T = Cr^n$ for r as a function of T.

(a) Take the logarithm (we'll arbitrarily use base 10) of both sides of $T = Cr^n$ and simplify to obtain:

$$\log(T) = \log(Cr^n) = \log C + \log r^n$$
$$= n\log r + \log C$$

Note that this equation is of the form $y = mx + b$. Hence a graph of log T vs. log r should be linear with a slope of n and a log T-intercept log C.

The following graph of log T versus log r was created using a spreadsheet program. The equation shown on the graph was obtained using Excel's ″Add Trendline″ function. (Excel's ″Add Trendline″ function uses regression analysis to generate the trendline.)



From the regression analysis we note that:

$$n = \boxed{1.50},$$

$$C = 10^{1.2311} = \boxed{17.0\,\text{y}/(\text{Gm})^{3/2}},$$

and

$$T = \boxed{\left(17.0\,\text{y}/(\text{Gm})^{3/2}\right)r^{1.50}} \qquad (1)$$

(*b*) Solve equation (1) for the radius of the planet's orbit:

$$r = \left(\frac{T}{17.0\,\text{y}/(\text{Gm})^{3/2}}\right)^{2/3}$$

Substitute numerical values and evaluate r:

$$r = \left(\frac{6.20\,\text{y}}{17.0\,\text{y}/(\text{Gm})^{3/2}}\right)^{2/3} = \boxed{0.510\text{ Gm}}$$

76 ••• The period T of a simple pendulum depends on the length L of the pendulum and the acceleration of gravity g (dimensions L/T^2). (*a*) Find a simple combination of L and g that has the dimensions of time. (*b*) Check the dependence of the period T on the length L by measuring the period (time for a complete swing back and forth) of a pendulum for two different values of L. (*c*) The correct formula relating T to L and g involves a constant that is a multiple of π, and cannot be obtained by the dimensional analysis of Part (*a*). It can be found by

experiment as in Part (*b*) if g is known. Using the value $g = 9.81$ m/s^2 and your experimental results from Part (*b*), find the formula relating T to L and g.

Picture the Problem We can express the relationship between the period T of the pendulum, its length L, and the acceleration of gravity g as $T = CL^a g^b$ and perform dimensional analysis to find the values of a and b and, hence, the function relating these variables. Once we've performed the experiment called for in Part (*b*), we can determine an experimental value for C.

(*a*) Express T as the product of L and g raised to powers a and b:

$$T = CL^a g^b \qquad (1)$$

where C is a dimensionless constant.

Write this equation in dimensional form:

$$[T] = [L]^a [g]^b$$

Substituting the dimensions of the physical quantities yields:

$$\mathrm{T} = \mathrm{L}^a \left(\frac{\mathrm{L}}{\mathrm{T}^2}\right)^b$$

Because L does not appear on the left-hand side of the equation, we can write this equation as:

$$\mathrm{L}^0\mathrm{T}^1 = \mathrm{L}^{a+b}\mathrm{T}^{-2b}$$

Equate the exponents to obtain:

$$a + b = 0 \text{ and } -2b = 1$$

Solve these equations simultaneously to find a and b:

$$a = \tfrac{1}{2} \text{ and } b = -\tfrac{1}{2}$$

Substitute in equation (1) to obtain:

$$T = CL^{1/2} g^{-1/2} = \boxed{C\sqrt{\frac{L}{g}}} \qquad (2)$$

(*b*) If you use pendulums of lengths 1.0 m and 0.50 m; the periods should be about:

$$T(1.0\,\mathrm{m}) = \boxed{2.0\,\mathrm{s}}$$

and

$$T(0.50\,\mathrm{m}) = \boxed{1.4\,\mathrm{s}}$$

(*c*) Solving equation (2) for C yields:

$$C = T\sqrt{\frac{g}{L}}$$

Evaluate C with L = 1.0 m and T = 2.0 s:

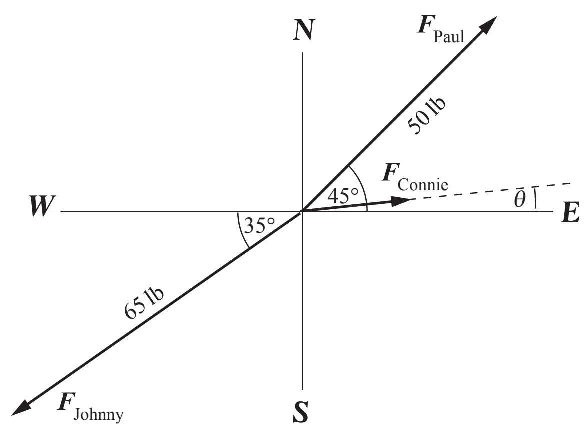
$$C=(2.0\,\text{s})\sqrt{\frac{9.81\,\text{m/s}^2}{1.0\,\text{m}}}=6.26\approx 2\pi$$

Substitute in equation (2) to obtain:

$$T=\boxed{2\pi\sqrt{\frac{L}{g}}}$$

77 ••• A sled at rest is suddenly pulled in three horizontal directions at the same time but it goes nowhere. Paul pulls to the northeast with a force of 50 lb. Johnny pulls at an angle of 35° south of due west with a force of 65 lb. Connie pulls with a force to be determined. (*a*) Express the boys' two forces in terms of the usual unit vectors (*b*) Determine the third force (from Connie), expressing it first in component form and then as a magnitude and angle (direction).

Picture the Problem A diagram showing the forces exerted by Paul, Johnny, and Connie is shown below. Once we've expressed the forces exerted by Paul and Johnny in vector form we can use them to find the force exerted by Connie.



(*a*) The force that Paul exerts is:

$$\vec{F}_{\text{Paul}}=[(50\,\text{lb})\cos 45°]\hat{i}+[(50\,\text{lb})\sin 45°]\hat{j}=(35.4\,\text{lb})\hat{i}+(35.4\,\text{lb})\hat{j}$$
$$=\boxed{(35\,\text{lb})\hat{i}+(35\,\text{lb})\hat{j}}$$

The force that Johnny exerts is:

$$\vec{F}_{\text{Johnny}}=[(65\,\text{lb})\cos 215°]\hat{i}+[(65\,\text{lb})\sin 215°]\hat{j}=(-53.2\,\text{lb})\hat{i}-(37.3\,\text{lb})\hat{j}$$
$$=\boxed{(-53\,\text{lb})\hat{i}+(-37\,\text{lb})\hat{j}}$$

The sum of the forces exerted by Paul and Johnny is:

$$\begin{aligned}\vec{F}_{\text{Paul}}+\vec{F}_{\text{Johnny}}&=(35.4\text{ lb})\hat{i}+(35.4\text{ lb})\hat{j}-(53.2\text{ lb})\hat{i}-(37.3\text{ lb})\hat{j}\\&=(-17.8\text{ lb})\hat{i}-(1.9\text{ lb})\hat{j}\end{aligned}$$

(*b*) The condition that the three forces must satisfy is:

$$\vec{F}_{\text{Paul}}+\vec{F}_{\text{Johnny}}+\vec{F}_{\text{Connie}}=0$$

Solving for $\vec{F}_{\text{Connie}}$ yields:

$$\vec{F}_{\text{Connie}}=-\left(\vec{F}_{\text{Paul}}+\vec{F}_{\text{Johnny}}\right)$$

Substitute for $\vec{F}_{\text{Paul}}+\vec{F}_{\text{Johnny}}$ to obtain:

$$\begin{aligned}\vec{F}_{\text{Connie}}&=-\left[(-17.8\text{ lb})\hat{i}-(1.9\text{ lb})\hat{j}\right]\\&=\boxed{(18\text{ lb})\hat{i}+(1.9\text{ lb})\hat{j}}\end{aligned}$$

The magnitude of $\vec{F}_{\text{Connie}}$ is:

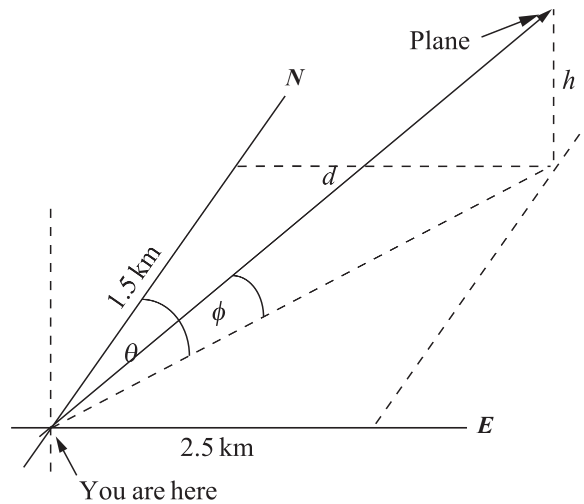
$$F_{\text{Connie}}=\sqrt{(17.8\text{ lb})^2+(1.9\text{ lb})^2}=\boxed{18\text{ lb}}$$

The direction that the force exerted by Connie acts is given by:

$$\theta=\tan^{-1}\left(\frac{1.9\text{ lb}}{17.8\text{ lb}}\right)=\boxed{6.1^\circ\text{ N of E}}$$

78 ••• You spot a plane that is 1.50 km North, 2.5 km East and at an altitude of 5.0 km above your position. (*a*) How far from you is the plane? (*b*) At what angle from due north (in the horizontal plane) are you looking? (*c*) Determine the plane's position vector (from your location) in terms of the unit vectors, letting $\hat{i}$ be toward the east direction, $\hat{j}$ be toward the north direction, and $\hat{k}$ be vertically upward. (*d*) At what elevation angle (above the horizontal plane of Earth) is the airplane?

Picture the Problem A diagram showing the given information is shown below. We can use the Pythagorean Theorem, trigonometry, and vector algebra to find the distance, angles, and expression called for in the problem statement.



(a) Use the Pythagorean Theorem to express d in terms of h and ℓ:

$$d = \sqrt{\ell^2 + h^2}$$

Substitute numerical values and evaluate d:

$$d = \sqrt{(2.5\text{ km})^2 + (1.5\text{ km})^2 + (5.0\text{ km})^2} = \boxed{5.8\text{ km}}$$

(b) Use trigonometry to evaluate the angle from due north at which you are looking at the plane:

$$\theta = \tan^{-1}\left(\frac{2.5\text{ km}}{1.5\text{ km}}\right) = \boxed{59^\circ\text{ E of N}}$$

(c) We can use the coordinates of the plane relative to your position to express the vector $\vec{\boldsymbol{d}}$:

$$\vec{\boldsymbol{d}} = \boxed{(2.5\text{ km})\hat{\boldsymbol{i}} + (1.5\text{ km})\hat{\boldsymbol{j}} + (5.0\text{ km})\hat{\boldsymbol{k}}}$$

(d) Express the elevation angle ϕ in terms of h and ℓ:

$$\phi = \tan^{-1}\left(\frac{h}{\ell}\right)$$

Substitute numerical values and evaluate ϕ:

$$\phi = \tan^{-1}\left(\frac{5.0\text{ km}}{\sqrt{(2.5\text{ km})^2 + (1.5\text{ km})^2}}\right) = \boxed{60^\circ\text{ above the horizon}}$$

Chapter 2
Motion in One Dimension

Conceptual Problems

1 • What is the average velocity over the ″round trip″ of an object that is launched straight up from the ground and falls straight back down to the ground?

Determine the Concept The "average velocity" is being requested as opposed to "average speed".

The average velocity is defined as the change in position or displacement divided by the change in time.

$$v_{av} = \frac{\Delta y}{\Delta t}$$

The change in position for any "round trip" is zero by definition. So the ***average velocity*** for any round trip must also be zero.

$$v_{av} = \frac{\Delta y}{\Delta t} = \frac{0}{\Delta t} = \boxed{0}$$

2 • An object thrown straight up falls back and is caught at the same place it is launched from. Its time of flight is T, its maximum height is H. Neglect air resistance. The correct expression for its average speed for the entire flight is (*a*) H/T, (*b*) 0, (*c*) $H/(2T)$, and (*d*) $2H/T$.

Determine the Concept The important concept here is that "average speed" is being requested as opposed to "average velocity".

Under all circumstances, including **constant acceleration**, the definition of the average speed is the ratio of the total distance traveled ($H + H$) to the elapsed time, in this case $2H/T$. $\boxed{(d)}$ is correct.

Remarks: **Because this motion involves a round trip, if the question asked for "average velocity," the answer would be zero.**

3 • Using the information in the previous question, what is its average speed just for the first half of the trip? What is its average velocity for the second half of the trip? (Answer in terms of H and T.)

Determine the Concept Under all circumstances, including ***constant acceleration***, the definition of the average speed is the ratio of the total distance traveled to the elapsed time. The average velocity, on the other hand, is the ratio of the displacement to the elapsed time.

The average speed for the first half of the trip is the height to which the object rises divided by one-half its time of flight:

$$v_{\text{av, 1st half}} = \frac{H}{\frac{1}{2}T} = \boxed{\frac{2H}{T}}$$

The average velocity for the second half of the trip is the distance the object falls divided by one-half its time of flight:

$$\text{vel}_{\text{av, 2nd half}} = \frac{-H}{\frac{1}{2}T} = \boxed{-\frac{2H}{T}}$$

Remarks: We could also say that the average velocity for the second half of the trip is –2*H*/*T*.

4 • Give an everyday example of one-dimensional motion where (*a*) the velocity is westward and the acceleration is eastward, and (*b*) the velocity is northward and the acceleration is northward.

Determine the Concept The important concept here is that $a = dv/dt$, where a is the acceleration and v is the velocity. Thus, the acceleration is positive if dv is positive; the acceleration is negative if dv is negative.

(*a*) An example of one-dimensional motion where the velocity is westward and acceleration is eastward is a car traveling westward and slowing down.

(*b*)An example of one-dimensional motion where the velocity is northward and the acceleration is northward is a car traveling northward and speeding up.

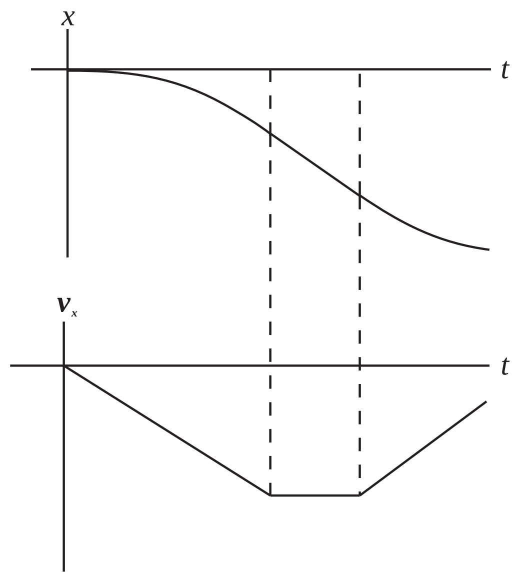
5 • **[SSM]** Stand in the center of a large room. Call the direction to your right ″positive,″ and the direction to your left ″negative.″ Walk across the room along a straight line, using a constant acceleration to quickly reach a steady speed along a straight line in the negative direction. After reaching this steady speed, keep your velocity negative but make your acceleration positive. (*a*) Describe how your speed varied as you walked. (*b*) Sketch a graph of x versus t for your motion. Assume you started at $x = 0$. (*c*) Directly under the graph of Part (*b*), sketch a graph of v_x versus t.

Determine the Concept The important concept is that when both the acceleration and the velocity are in the same direction, the speed increases. On the other hand, when the acceleration and the velocity are in opposite directions, the speed decreases.

(*a*) Your speed increased from zero, stayed constant for a while, and then decreased.

(*b*) A graph of your position as a function of time is shown to the right. Note that the slope starts out equal to zero, becomes more negative as the speed increases, remains constant while your speed is constant, and becomes less negative as your speed decreases.

(*c*) The graph of $v(t)$ consists of a straight line with negative slope (your acceleration is constant and negative) starting at (0,0), then a flat line for a while (your acceleration is zero), and finally an approximately straight line with a positive slope heading to $v = 0$.



6 • True/false: The displacement *always* equals the product of the average velocity and the time interval. Explain your choice.

Determine the Concept True. We can use the definition of average velocity to express the displacement Δx as $\Delta x = v_{av}\Delta t$. Note that, if the acceleration is constant, the average velocity is also given by $v_{av} = (v_i + v_f)/2$.

7 • Is the statement "for an object's velocity to remain constant, its acceleration must remain zero" true or false? Explain your choice.

Determine the Concept True. Acceleration is the slope of the velocity versus time curve, $a = dv/dt$; while velocity is the slope of the position versus time curve, $v = dx/dt$. The speed of an object is the magnitude of its velocity. Zero acceleration implies that the velocity is constant. If the velocity is constant (including zero), the speed must also be constant.

8 • Draw careful graphs of the position and velocity and acceleration over the time period $0 \lesssim t \lesssim 30$ s for a cart that, in succession, has the following motion. The cart is moving at the constant speed of 5.0 m/s in the $+x$ direction. It passes by the origin at $t = 0.0$ s. It continues on at 5.0 m/s for 5.0 s, after which it gains speed at the constant rate of 0.50 m/s each second for 10.0 s. After gaining speed for 10.0 s, the cart loses speed at the constant rate of 0.50 m/s for the next 15.0 s.

Determine the Concept Velocity is the slope of the position versus time curve and acceleration is the slope of the velocity versus time curve. The following graphs were plotted using a spreadsheet program.

9 • True/false; Average velocity *always* equals one-half the sum of the initial and final velocities. Explain your choice.

Determine the Concept False. The average velocity is defined (for any acceleration) as the change in position (the displacement) divided by the change in time $v_{av} = \Delta x/\Delta t$. It is always valid. If the acceleration remains constant the average velocity is also given by

$$v_{av} = \frac{v_i + v_f}{2}$$

Consider an engine piston moving up and down as an example of non-constant velocity. For one complete cycle, $v_f = v_i$ and $x_i = x_f$ so $v_{av} = \Delta x/\Delta t$ is zero. The formula involving the mean of v_f and v_i cannot be applied because the acceleration is not constant, and yields an incorrect nonzero value of v_i.

10 • Identical twin brothers standing on a horizontal bridge each throw a rock straight down into the water below. They throw rocks at exactly the same time, but one hits the water before the other. How can this be? Explain what they did differently. Ignore any effects due to air resistance.

Determine the Concept This can occur if the rocks have different initial speeds. Ignoring air resistance, the acceleration is constant. Choose a coordinate system in which the origin is at the point of release and upward is the positive direction. From the constant-acceleration equation $y = y_0 + v_0 t + \frac{1}{2}at^2$ we see that the only way two objects can have the same acceleration ($-g$ in this case) and cover the same distance, $\Delta y = y - y_0$, in different times would be if the initial velocities of the two rocks were different. Actually, the answer would be the same whether or not the acceleration is constant. It is just easier to see for the special case of constant acceleration.

11 •• [SSM] Dr. Josiah S. Carberry stands at the top of the Sears Tower in Chicago. Wanting to emulate Galileo, and ignoring the safety of the pedestrians below, he drops a bowling ball from the top of the tower. One second later, he drops a second bowling ball. While the balls are in the air, does their separation (*a*) increase over time, (*b*) decrease, (*c*) stay the same? Ignore any effects due to air resistance.

Determine the Concept Neglecting air resistance, the balls are in free fall, each with the same free-fall acceleration, which is a constant.

At the time the second ball is released, the first ball is already moving. Thus, during any time interval their velocities will increase by exactly the same amount. What can be said about the speeds of the two balls? *The first ball will always be moving faster than the second ball.* This being the case, what happens to the separation of the two balls while they are both falling? *Their separation increases.* $\boxed{(a)}$ is correct.

12 •• Which of the position-versus-time curves in Figure 2-28 best shows the motion of an object (*a*) with positive acceleration, (*b*) with constant positive velocity, (*c*) that is always at rest, and (*d*) with negative acceleration? (There may be more than one correct answer for each part of the problem.)

Determine the Concept The slope of an $x(t)$ curve at any point in time represents the speed at that instant. The way the slope changes as time increases gives the sign of the acceleration. If the slope becomes less negative or more positive as time increases (as you move to the right on the time axis), then the acceleration is positive. If the slope becomes less positive or more negative, then the acceleration is negative. The slope of the slope of an $x(t)$ curve at any point in time represents the acceleration at that instant.

(*a*) The correct answer is $\boxed{(d)}$. The slope of curve (*d*) is positive and increasing. Therefore the velocity and acceleration are positive. We would need more information to conclude that *a* is constant.

(*b)* The correct answer is $\boxed{(b)}$. The slope of curve (*b*) is positive and constant. Therefore the velocity is positive and constant.

(*c*) The correct answer is $\boxed{(e)}$. The slope of curve (*e*) is zero. Therefore, the velocity and acceleration are zero and the object remains at the same position.

(*d*) The correct answers are $\boxed{(a)\text{ and }(c)}$. The slope of curve (*a*) is negative and becomes more negative as time increases. Therefore the velocity is negative and the acceleration is negative. The slope of curve (*c*) is positive and decreasing. Therefore the velocity is positive and the acceleration is negative.

13 •• [SSM] Which of the velocity-versus-time curves in figure 2-29 best describes the motion of an object (*a*) with constant positive acceleration, (*b*) with positive acceleration that is decreasing with time, (*c*) with positive acceleration that is increasing with time, and (*d*) with no acceleration? (There may be more than one correct answer for each part of the problem.)

Determine the Concept The slope of a $v(t)$ curve at any point in time represents the acceleration at that instant.

(*a*) The correct answer is $\boxed{(b)}$. The slope of curve (*b*) is constant and positive. Therefore the acceleration is constant and positive.

(*b*) The correct answer is $\boxed{(c)}$. The slope of curve (*c*) is positive and decreasing with time. Therefore the acceleration is positive and decreasing with time.

(*c*) The correct answer is $\boxed{(d)}$. The slope of curve (*d*) is positive and increasing with time. Therefore the acceleration is positive and increasing with time.

(*d*) The correct answer is $\boxed{(e)}$. The slope of curve (*e*) is zero. Therefore the velocity is constant and the acceleration is zero.

14 •• The diagram in Figure 2-30 tracks the location of an object moving in a straight line along the *x* axis. Assume that the object is at the origin at $t = 0$. Of the five times shown, which time (or times) represents when the object is (*a*) farthest from the origin, (*b*) at rest for an instant, (*c*) in the midst of being at rest for awhile, and (*d*) moving away from the origin?

Determine the Concept Because this graph is of distance-versus-time we can use its displacement from the time axis to draw conclusions about how far the object is from the origin. We can also use the instantaneous slope of the graph to decide whether the object is at rest and whether it is moving toward or away from the origin.

(*a*) The correct answer is $\boxed{\text{B}.}$ Because the object's initial position is at $x = 0$, point B represents the instant that the object is farthest from $x = 0$.

(*b*) The correct answers are $\boxed{\text{B and D.}}$ Because the slope of the graph is zero at points B and D, the velocity of the object is zero and it is momentarily at rest at these points.

(*c*) The correct answer is $\boxed{E}$. Because the graph is a horizontal line with zero slope, the object remains at rest at the same position (its velocity is zero).

(*d*) The correct answer is $\boxed{\text{A.}}$ Because the slope of the graph is positive at point A, the velocity of the object is positive and it is moving away from the origin.

15 •• **[SSM]** An object moves along a straight line. Its position versus time graph is shown in Figure 2-30. At which time or times is its (*a*) speed at a minimum, (*b*) acceleration positive, and (*c*) velocity negative?

Determine the Concept Because this graph is of distance-versus-time we can use its instantaneous slope to describe the object's speed, velocity, and acceleration.

(*a*) The minimum speed is at $\boxed{\text{B, D, and E}}$, where it is zero. In the one-dimensional motion shown in the figure, the velocity is a minimum when the slope of a position-versus-time plot goes to zero (i.e., the curve becomes horizontal). At these points the velocity is zero and, therefore, the speed is zero.

(*b*) The acceleration is positive at points $\boxed{\text{A and D.}}$ Because the slope of the graph is increasing at these points, the velocity of the object is increasing and its acceleration is positive.

(*c*) The velocity is negative at point $\boxed{\text{C.}}$ Because the slope of the graph is negative at point C, the velocity of the object is negative.

16 •• For each of the four graphs of x versus t in Figure 2-31 answer the following questions. (*a*) Is the velocity at time t_2 greater than, less than, or equal to the velocity at time t_1? (*b*) Is the speed at time t_2 greater than, less than, or equal to the speed at time t_1?

Determine the Concept In one-dimensional motion, the velocity is the slope of a position-versus-time plot and can be either positive or negative. On the other hand, the speed is the magnitude of the velocity and can only be positive. We'll use v to denote velocity and the word "speed" for how fast the object is moving.

(*a*)
curve a: $v(t_2) < v(t_1)$
curve b: $v(t_2) = v(t_1)$
curve c: $v(t_2) > v(t_1)$
curve d: $v(t_2) < v(t_1)$

(*b*)
curve a: $\text{speed}(t_2) < \text{speed}(t_1)$
curve b: $\text{speed}(t_2) = \text{speed}(t_1)$
curve c: $\text{speed}(t_2) < \text{speed}(t_1)$
curve d: $\text{speed}(t_2) > \text{speed}(t_1)$

17 •• True/false: Explain your reasoning for each answer. If the answer is true, give an example.

(*a*) If the acceleration of an object is always zero, then it cannot be moving.
(*b*) If the acceleration of an object is always zero, then its *x*-versus-*t* curve must be a straight line.
(*c*) If the acceleration of an object is nonzero at an instant, it may be momentarily at rest at that instant.

Explain your reasoning for each answer. If an answer is true, give an example.

(*a*) False. An object moving in a straight line with constant speed has zero acceleration.

(*b*) True. If the acceleration of the object is zero, then its speed must be constant. The graph of *x*-versus-*t* for an object moving with constant speed is a straight line.

(c) True. A ball thrown upward is momentarily at rest when it is at the top of its trajectory. Its acceleration, however, is non-zero at this instant. Its value is the same as it was just before it came to rest and after it has started its descent.

18 •• A hard-thrown tennis ball is moving horizontally when it bangs into a vertical concrete wall at perpendicular incidence. The ball rebounds straight back off the wall. Neglect any effects due to gravity for the small time interval described here. Assume that towards the wall is the $+x$ direction. What are the directions of its velocity and acceleration (a) just before hitting the wall, (b) at maximum impact, and (c) just after leaving the wall.

Determine the Concept The tennis ball will be moving with constant velocity immediately before and after its collision with the concrete wall. It will be accelerated during the duration of its collision with the wall.

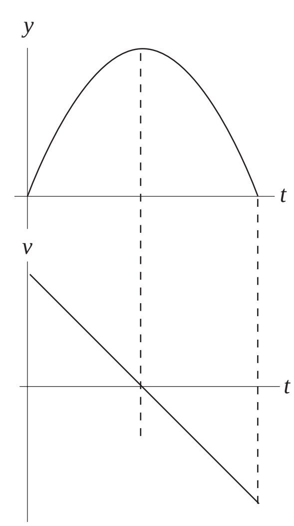
(a) Just before hitting the wall the velocity of the ball is in the $+x$ direction and, because its velocity is constant, its acceleration is zero.

(b) At maximum impact, the ball is reversing direction and its velocity is zero. Its acceleration is in the $-x$ direction.

(c) Just after leaving the wall, the velocity of the ball is in the $-x$ direction and constant. Because its velocity is constant, its acceleration is zero.

19 •• **[SSM]** A ball is thrown straight up. Neglect any effects due to air resistance. (a) What is the velocity of the ball at the top of its flight? (b) What is its acceleration at that point? (c) What is different about the velocity and acceleration at the top of the flight if instead the ball impacts a horizontal ceiling very hard and then returns.

Determine the Concept In the absence of air resistance, the ball will experience a constant acceleration and the graph of its position as a function of time will be parabolic. In the graphs to the right, a coordinate system was chosen in which the origin is at the point of release and the upward direction is the $+y$ direction. The top graph shows the position of the ball as a function of time and the bottom graph shows the velocity of a ball as a function of time.



(a) $v_{\text{top of flight}} = \boxed{0}$

(b) The acceleration of the ball is the same at every point of its trajectory, including the point at which $v = 0$ (at the top of its flight). Hence $a_{\substack{\text{top of}\\ \text{flight}}} = \boxed{-g}$.

(*c*) If the ball impacts a horizontal ceiling very hard and then returns, its velocity at the top of its flight is still zero and its acceleration is still downward but greater than g in magnitude.

20 •• An object that is launched straight up from the ground, reaches a maximum height H, and falls straight back down to the ground, hitting it T seconds after launch. Neglect any effects due to air resistance. (*a*) Express the average speed for the entire trip as a function of H and T. (*b*) Express the average speed for the same interval of time as a function of the initial launch speed v_0.

Picture the Problem The average speed is being requested as opposed to average velocity. We can use the definition of average speed as distance traveled divided by the elapsed time and the expression for the average speed of an object when it is experiencing constant acceleration to express v_{av} in terms of v_0.

(*a*) The average speed is defined as the total distance traveled divided by the change in time:

$$v_{av} = \frac{\text{total distance traveled}}{\text{total time}}$$

Substitute for the total distance traveled and the total time and simplify to obtain:

$$v_{av} = \frac{H+H}{T} = \boxed{\frac{2H}{T}}$$

(*b*) The average speed for the upward flight of the object is given by:

$$v_{av,\,up} = \frac{v_0+0}{2} = \frac{H}{\frac{1}{2}T} \Rightarrow \frac{H}{T} = \tfrac{1}{4}v_0$$

The average speed for the same interval of time as a function of the initial launch speed v_0 is twice the average speed during the upward portion of the flight:

$$v_{av} = 2v_{av,\,up} = 2\left(\tfrac{1}{4}v_0\right) = \boxed{\tfrac{1}{2}v_0}$$

Because $v_0 \neq 0$, the average speed is not zero.

Remarks: 1) Because this motion involves a roundtrip, if the question asked for "average velocity", the answer would be zero. 2) Another easy way to obtain this result is take the absolute value of the velocity of the object to obtain a graph of its speed as a function of time. A simple geometric argument leads to the result we obtained above.

21 •• A small lead ball is thrown directly upward. Neglect any effects due to air resistance. True or false: (*a*) The magnitude of its acceleration decreases on the way up. (*b*) The direction of its acceleration on its way down is opposite to the direction of its acceleration on its way up. (*c*) The direction of its velocity on its way down is opposite to the direction of its velocity on its way up.

Determine the Concept For free fall, the acceleration is the same (g) throughout the entire flight.

(*a*) False. The velocity of the ball decreases at a steady rate. This means that the acceleration of the ball is constant.

(*b*) False. The velocity of the ball decreases at a steady rate (g) throughout its entire flight.

(*c*) True. On the way up the velocity vector points upward and on the way down it points downward.

22 •• At $t = 0$, object A is dropped from the roof of a building. At the same instant, object B is dropped from a window 10 m below the roof. Air resistance is negligible. During the descent of B to the ground, the distance between the two objects (*a*) is proportional to t, (*b*) is proportional to t^2, (*c*) decreases, (*d*) remains 10 m throughout.

Determine the Concept Both objects experience the same constant acceleration. Choose a coordinate system in which downward is the positive direction and use a constant-acceleration equation to express the position of each object as a function of time.

Using constant-acceleration equations, express the positions of both objects as functions of time:

$$x_A = x_{0,A} + v_0 t + \tfrac{1}{2} g t^2$$

and

$$x_B = x_{0,B} + v_0 t + \tfrac{1}{2} g t^2$$

where $v_0 = 0$.

Express the separation of the two objects by evaluating $x_B - x_A$:

$$x_B - x_A = x_{0,B} - x_{0,A} = 10\,\text{m}$$

$\boxed{(d)}$ is correct.

23 •• You are driving a Porsche that accelerates uniformly from 80.5 km/h (50 mi/h) at $t = 0.00$ to 113 km/h (70 mi/h) at $t = 9.00$ s. (*a*) Which graph in Figure 2-32 best describes the velocity of your car? (*b*) Sketch a position-versus-time graph showing the location of your car during these nine seconds, assuming we let its position x be zero at $t = 0$.

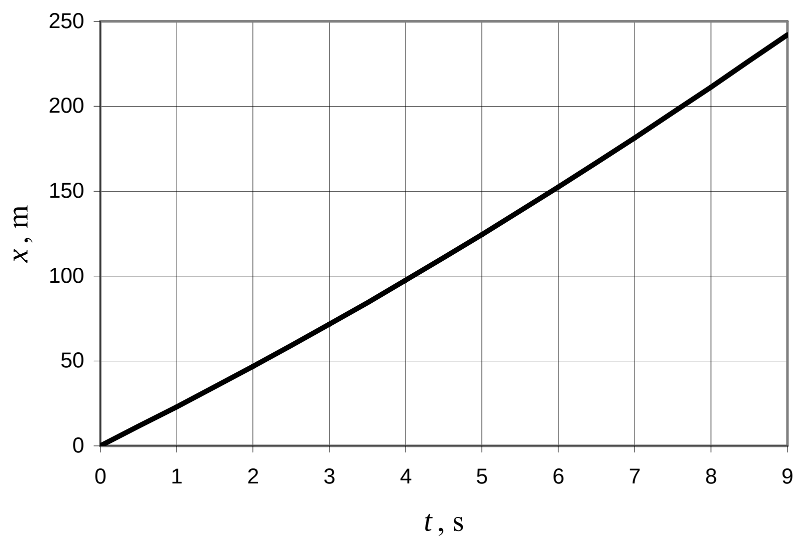
Determine the Concept Because the Porsche accelerates uniformly, we need to look for a graph that represents constant acceleration.

(*a*) Because the Porsche has a constant acceleration that is positive (the velocity is increasing), we must look for a velocity-versus-time curve with a positive constant slope and a nonzero intercept. Such a graph is shown in $\boxed{(c).}$

(*b*) Use the data given in the problem statement to determine that the acceleration of the Porsche is 1.00 m/s^2 and that its initial speed is 22.4 m/s. The equation describing the position of the car as a function of time is

$$x = \left(22.4\ \text{m/s}^2\right)t + \tfrac{1}{2}\left(1.00\ \text{m/s}^2\right)t^2.$$

The following graph of this equation was plotted using a spreadsheet program.



24 •• A small heavy object is dropped from rest and falls a distance *D* in a time *T*. After it has fallen for a time 2*T*, what will be its (*a*) fall distance from its initial location in terms of *D*, (*b*) its speed in terms of *D* and *t*, and (*c*) its acceleration? (Neglect air resistance.)

Picture the Problem In the absence of air resistance, the object experiences constant acceleration. Choose a coordinate system in which the downward direction is positive and use the constant-acceleration equation to describe its motion.

(*a*) Relate the distance *D* that the object, released from rest, falls in time *t*:

$$x(t) = D = \tfrac{1}{2}gt^2 \qquad (1)$$

Evaluate *x*(2*t*) to obtain:

$$x(2t) = \tfrac{1}{2}g(2t)^2 = 2gt^2 \qquad (2)$$

Dividing equation (2) by equation (1) and simplifying yields:

$$\frac{x(2t)}{D} = \frac{2gt^2}{\frac{1}{2}gt^2} = 4 \Rightarrow x(2t) = \boxed{4D}$$

(*b*) Express the speed of the object as a function of time:

$$v = v_0 + gt$$

or, because $v_0 = 0$,

$$v = gt \qquad (3)$$

Solving equation (1) for g yields:

$$g = \frac{2x}{t^2}$$

Substitute for g in equation (3) to obtain:

$$v = \frac{2x}{t^2}t = \frac{2x}{t} \qquad (4)$$

Evaluating equation (4) at time $2t$ and simplifying yields:

$$v(2t) = \frac{2x(2t)}{2t} = \boxed{\frac{4D}{t}}$$

(*c*) The acceleration of the object is independent of time (that is, it is constant) and is equal to $\boxed{g.}$

25 •• In a race, at an instant when two horses are running right next to each other and in the same direction (the $+x$ direction), horse A's instantaneous velocity and acceleration are $+10$ m/s and $+2.0$ m/s^2 respectively, and horse B's instantaneous velocity and acceleration are $+12$ m/s and -1.0 m/s^2 respectively. Which horse is passing the other at this instant? Explain.

Determine the Concept The information about the horses' accelerations is irrelevant to the determination of which horse is passing the other at this instant. The horse running with the greater instantaneous velocity will by passing the slower horse. Hence $\boxed{\text{B is passing A.}}$ The accelerations are relevant to the determination of which horse will be in the lead at some later time.

26 •• True or false: (*a*) The equation $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ is always valid for all particle motion in one dimension. (*b*) If the velocity at a given instant is zero, the acceleration at that instant must also be zero. (*c*) The equation $\Delta x = v_{av}\Delta t$ holds for all particle motion in one dimension.

Determine the Concept As long as the acceleration remains constant the following constant-acceleration equations hold. If the acceleration is not constant, they do not, in general, give correct results except by coincidence.

$$x = x_0 + v_0 t + \tfrac{1}{2}at^2 \qquad v = v_0 + at \qquad v^2 = v_0^2 + 2a\Delta x \qquad v_{av} = \frac{v_i + v_f}{2}$$

(*a*) False. This statement is true if and only if the acceleration is constant.

(*b*) False. Consider a rock thrown straight up into the air. At the "top" of its flight, the velocity is zero but it is changing (otherwise the velocity would remain zero and the rock would hover); therefore the acceleration is not zero.

(*c*) True. The definition of average velocity, $v_{\text{av}} = \Delta x/\Delta t$, requires that this always be true.

27 •• If an object is moving in a straight line at constant acceleration, its instantaneous velocity halfway through any time interval is (*a*) greater than its average velocity, (*b*) less than its average velocity, (*c*) equal to its average velocity, (*d*) half its average velocity, (*e*) twice its average velocity.

Determine the Concept Because the acceleration of the object is constant, the constant-acceleration equations can be used to describe its motion. The special expression for average velocity for constant acceleration is $v_{\text{av}} = \dfrac{v_{\text{i}} + v_{\text{f}}}{2}$. $\boxed{(c)}$ is correct.

28 •• A turtle, seeing his owner put some fresh lettuce on the opposite side of his terrarium, begins to accelerate (at a constant rate) from rest at time $t = 0$, heading directly toward the food. Let t_1 be the time at which the turtle has covered half the distance to his lunch. Derive an expression for the ratio of t_2 to t_1, where t_2 is the time at which the turtle reaches the lettuce.

Picture the Problem We are asked, essentially, to determine the time t_2, at which a displacement, Δx, is twice what it was at an earlier time, t_1. The turtle is crawling with constant acceleration so we can use the constant-acceleration equation $\Delta x = v_{0x}\Delta t + \frac{1}{2}a_x(\Delta t)^2$ to describe the turtle's displacement as a function of time.

Express the displacement Δt of the turtle at the end of a time interval Δt:	$\Delta x = v_{0x}\Delta t + \frac{1}{2}a_x(\Delta t)^2$ or, because $v_{0x} = 0$, $\Delta x = \frac{1}{2}a_x(\Delta t)^2$
For the two time intervals:	$\Delta x_1 = \frac{1}{2}a_x t_1^2$ and $\Delta x_2 = \frac{1}{2}a_x t_2^2$
Express the ratio of Δx_2 to Δx_1 to obtain:	$\dfrac{\Delta x_2}{\Delta x_1} = \dfrac{\frac{1}{2}a_x t_2^2}{\frac{1}{2}a_x t_1^2} = \dfrac{t_2^2}{t_1^2}$ (1)
We're given that:	$\dfrac{\Delta x_2}{\Delta x_1} = 2$

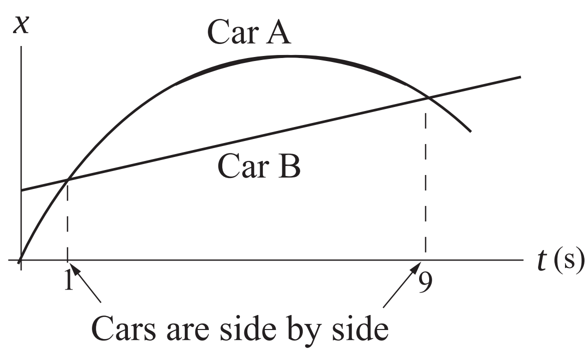
Substitute in equation (1) and simplify to obtain:

$$\frac{t_2^2}{t_1^2}=2\Rightarrow\frac{t_2}{t_1}=\boxed{\sqrt{2}}$$

29 •• [SSM] The positions of two cars in parallel lanes of a straight stretch of highway are plotted as functions of time in the Figure 2-33.Take positive values of *x* as being to the right of the origin. Qualitatively answer the following: (*a*) Are the two cars ever side by side? If so, indicate that time (those times) on the axis. (*b*) Are they always traveling in the same direction, or are they moving in opposite directions for some of the time? If so, when? (*c*) Are they ever traveling at the same velocity? If so, when? (*d*) When are the two cars the farthest apart? (*e*) Sketch (no numbers) the velocity versus time curve for each car.

Determine the Concept Given the positions of the two cars as a function of time, we can use the intersections of the curves and their slopes to answer these questions.

(*a*) The positions of cars A and B are the same at two places where the graphs cross.

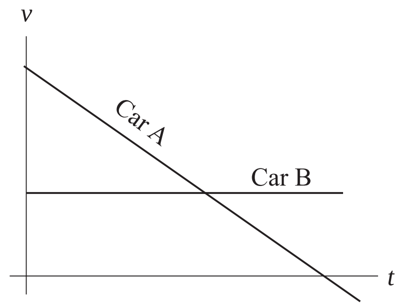


(*b*) When the slopes of the curves have opposite signs, the velocities of the cars are oppositely directed. Thus, after approximately 7 s, car A is moving leftward while car B is moving rightward. Before t = 7 s, the two cars are traveling in the same direction.

(*c*) The two cars have the same velocity when their curves have the same slopes. This occurs at about 6 s.

(*d*) The time at which the two cars are farthest apart is roughly 6 s as indicated by the place at which, vertically, the two curves are farthest part.

(*e*)



30 •• A car driving at constant velocity passes the origin at time $t = 0$. At that instant, a truck, at rest at the origin, begins to accelerate uniformly from rest. Figure 2-34 shows a qualitative plot of the velocities of truck and car as functions of time. Compare their displacements (from the origin), velocities, and accelerations at the instant that their curves intersect.

Determine the Concept The graph is a plot of velocity versus time. Thus, where the two curves cross, the truck and car are, at that instant, moving with equal velocities. The slope of a velocity versus time curve is equal to the instantaneous acceleration – thus, since the curve that represents the truck's velocity has a positive slope, and the car's curve has zero slope, the truck is accelerating at a higher rate than the car. Finally, the displacements of the two cars are determined by calculating the areas under the curves. In this instance, the curve representing the truck's velocity as a function of time encloses a triangular area that is exactly half that of the curve representing the car's velocity. Thus, at the instant represented by the point where the curves intersect, the truck has gone half as far as has the car.

31 •• Reginald is out for a morning jog, and during the course of his run on a straight track, has a velocity that depends upon time as shown in Figure 2-35. That is, he begins at rest, and ends at rest, peaking at a maximum velocity v_{max} at an arbitrary time t_{max}. A second runner, Josie, runs throughout the time interval $t = 0$ to $t = t_f$ at a constant speed v_R, so that each has the same displacement during the time interval. Note: t_f is NOT twice t_{max}, but represents an arbitrary time. What is the relationship between v_J and v_{max}?

Determine the Concept In this problem we are presented with curves representing the velocity as a function of time for both runners. The area under each curve represents the displacement for each runner and we are told that Josie and Reginald each have the same displacement during the time interval of length t_f. Since this is the case, we can find the relationship between v_R and v_{max} by equating the areas under the two curves.

Express the condition on the displacement of the two runners:

$$\Delta x_R = \Delta x_J \quad (1)$$

Josie runs at a constant velocity v for the whole of the time interval. Express her displacement Δx_J:

$$\Delta x_J = v_J t_f$$

Reginald has a different velocity profile, one which results in a triangle of height v_{max} and length t_f. Express his displacement Δx_J:

$$\Delta x_R = \tfrac{1}{2} v_{max} t_f$$

Substitute for Δx_R and Δx_J in equation (1) and simplify to obtain:

$$\tfrac{1}{2} v_{max} t_f = v_J t_f \Rightarrow v_J = \boxed{\tfrac{1}{2} v_{max}}$$

32 •• Which graph (or graphs), if any, of v versus t in Figure 2-36 best describes the motion of a particle with (*a*) positive velocity and increasing speed, (*b*) positive velocity and zero acceleration, (*c*) constant non-zero acceleration, and (*d*) a speed decrease?

Determine the Concept The velocity of the particle is positive if the curve is above the $v = 0$ line (the t axis), and the acceleration is positive if the curve has a positive slope. The speed of the particle is the magnitude of its velocity.

(*a*) Graph $\boxed{(c)}$ describes the motion of a particle with positive velocity and increasing speed because $v(t)$ is above the t axis and has a positive slope.

(*b*) Graph $\boxed{(a)}$ describes the motion of a particle with positive velocity and zero acceleration because $v(t)$ is above the t axis and its slope is zero.

(*c*) Graphs $\boxed{(c), (d) \text{ and } (e)}$ describe the motion of a particle with constant non-zero acceleration because $v(t)$ is linear and has a non-zero slope.

(*d*) Graph $\boxed{(e)}$ describes the motion of a particle with a speed decrease because it shows the speed of the particle decreasing with time.

33 •• Which graph (or graphs), if any, of v_x versus t in Figure 2-36 best describes the motion of a particle with (*a*) negative velocity and increasing speed, (*b*) negative velocity and zero acceleration, (*c*) variable acceleration, and (*d*) increasing speed?

Determine the Concept The velocity of the particle is positive if the curve is above the $v = 0$ line (the t axis), and the acceleration is positive if the curve has a positive slope. The speed of the particle is the magnitude of its velocity.

(*a*) Graph $\boxed{(d)}$ describes the motion of a particle with negative velocity and increasing speed because *v*(*t*) is below the *t* axis and has a negative slope.

(*b*) Graph $\boxed{(b)}$ describes the motion of a particle with negative velocity and zero acceleration because *v*(*t*) is below the *t* axis and its slope is zero.

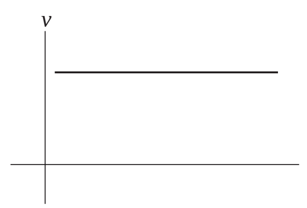
(*c*) None of these graphs describe the motion of a particle with a variable acceleration because *v*(*t*) is linear.

(*d*) Graphs $\boxed{(c)\text{ and }(d)}$ describe the motion of a particle with an increasing speed because they show the speed of the particle increasing with time.

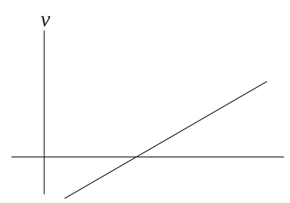
34 •• Sketch a *v*-versus-*t* curve for each of the following conditions: (*a*) Acceleration is zero and constant while velocity is not zero. (*b*) Acceleration is constant but not zero. (*c*) Velocity and acceleration are both positive. (*d*) Velocity and acceleration are both negative. (*e*) Velocity is positive and acceleration is negative. (*f*) Velocity is negative and acceleration is positive. (*g*) Velocity is momentarily zero but the acceleration is not zero.

Determine the Concept Acceleration is the slope of a velocity-versus-time curve.

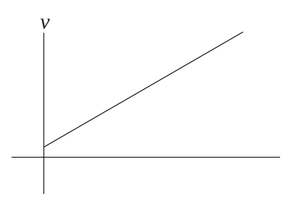
(*a*) Acceleration is zero and constant while velocity is not zero.



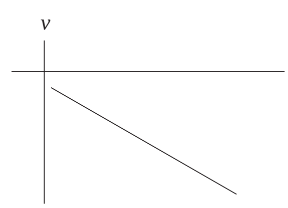
(*b*) Acceleration is constant but not zero.



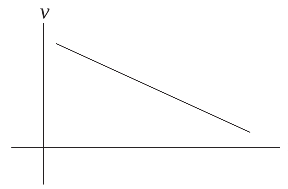
(*c*) Velocity and acceleration are both positive.



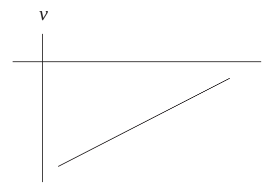
(*d*) Velocity and acceleration are both negative.



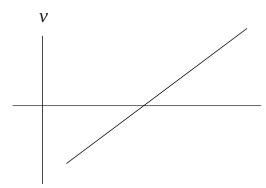
(*e*) Velocity is positive and acceleration is negative.



(*f*) Velocity is negative and acceleration is positive.



(*g*) Velocity is momentarily zero but the acceleration is not zero.



35 •• Figure 2-37 shows nine graphs of position, velocity, and acceleration for objects in motion along a straight line. Indicate the graphs that meet the following conditions: (*a*) Velocity is constant, (*b*) velocity reverses its direction, (*c*) acceleration is constant, and (*d*) acceleration is not constant. (*e*) Which graphs of position, velocity, and acceleration are mutually consistent?

Determine the Concept Velocity is the slope and acceleration is the slope of the slope of a position-versus-time curve. Acceleration is the slope of a velocity-versus-time curve.

(*a*) Graphs $\boxed{(a), (f), \text{and } (i)}$ describe motion at constant velocity. For constant velocity, *x* versus *t* must be a straight line; *v*-versus-*t* must be a horizontal straight line; and *a* versus *t* must be a straight horizontal line at $a = 0$.

(*b*) Graphs $\boxed{(c) \text{ and } (d)}$ describe motion in which the velocity reverses its direction. For velocity to reverse its direction *x*-versus-*t* must have a slope that changes sign and *v* versus *t* must cross the time axis. The acceleration cannot remain zero at all times.

(*c*) Graphs $\boxed{(a), (d), (e), (f), (h), \text{and } (i)}$ describe motion with constant acceleration. For constant acceleration, *x* versus *t* must be a straight horizontal line or a parabola, *v* versus *t* must be a straight line, and *a* versus *t* must be a horizontal straight line.

(*d*) Graphs $\boxed{(b),(c),\text{ and }(g)}$ describe motion with non-constant acceleration. For non-constant acceleration, *x* versus *t* must not be a straight line or a parabola; *v* versus *t* must not be a straight line, or *a* versus *t* must not be a horizontal straight line.

(*e*) The following pairs of graphs are mutually consistent: $\boxed{(a)\text{ and }(i),}$ $\boxed{(d)\text{ and }(h),}$ and $\boxed{(f)\text{ and }(i).}$ For two graphs to be mutually consistent, the curves must be consistent with the definitions of velocity and acceleration.

Estimation and Approximation

36 • While engrossed in thought about the scintillating lecture just delivered by your physics professor you mistakenly walk directly into the wall (rather than through the open lecture hall door). Estimate the magnitude of your average acceleration as you rapidly come to a halt.

Picture the Problem The speed of one's walk varies from person to person, but 1.0 m/s is reasonable. We also need to estimate a distance within which you would stop in such a case. We'll assume a fairly short stopping distance of 1.5 cm. We'll also assume (unrealistically) that you experience constant acceleration and choose a coordinate system in which the direction you are walking is the +*x* direction.

Using a constant-acceleration equation, relate your final speed to your initial speed, acceleration, and displacement while stopping:

$$v_{\text{f}}^2 = v_{\text{i}}^2 + 2a_x\Delta x \Rightarrow a_x = \frac{v_{\text{f}}^2 - v_{\text{i}}^2}{2\Delta x}$$

Substitute numerical values and evaluate the magnitude of your acceleration:

$$a_x = \left|\frac{(0)^2 - \left(1.0\,\frac{\text{m}}{\text{s}}\right)^2}{2\left(1.5\times10^{-2}\,\text{m}\right)}\right| = \boxed{33\ \text{m/s}^2}$$

37 • **[SSM]** Occasionally, people can survive falling large distances if the surface they land on is soft enough. During a traverse of the Eiger's infamous Nordvand, mountaineer Carlos Ragone's rock anchor gave way and he plummeted 500 feet to land in snow. Amazingly, he suffered only a few bruises and a wrenched shoulder. Assuming that his impact left a hole in the snow 4.0 ft deep, estimate his average acceleration as he slowed to a stop (that is, while he was impacting the snow).

Picture the Problem In the absence of air resistance, Carlos' acceleration is constant. Because all the motion is downward, let's use a coordinate system in which downward is the positive direction and the origin is at the point at which the fall began.

Using a constant-acceleration equation, relate Carlos' final velocity v_2 to his velocity v_1 just before his impact, his stopping acceleration a_s upon impact, and his stopping distance Δy:

$$v_2^2 = v_1^2 + 2a_s\Delta y \Rightarrow a_s = \frac{v_2^2 - v_1^2}{2\Delta y}$$

or, because $v_2 = 0$,

$$a_s = -\frac{v_1^2}{2\Delta y} \qquad (1)$$

Using a constant-acceleration equation, relate Carlos' speed just before impact to his acceleration during free-fall and the distance he fell h:

$$v_1^2 = v_0^2 + 2a_{\text{free-fall}}h$$

or, because $v_0 = 0$ and $a_{\text{free-fall}} = g$,

$$v_1^2 = 2gh$$

Substituting for v_1^2 in equation (1) yields:

$$a_s = -\frac{2gh}{2\Delta y}$$

Substitute numerical values and evaluate a_s:

$$a = -\frac{2(9.81\,\text{m/s}^2)(500\,\text{ft})}{2(4.0\,\text{ft})} = \boxed{-1.2\times10^3\,\text{m/s}^2}$$

Remarks: The magnitude of this acceleration is about 125*g*!

38 •• When we solve free-fall problems near Earth, it's important to remember that air resistance may play a significant role. If its effects are significant, we may get answers that are wrong by orders of magnitude if we ignore it. How can we tell when it is valid to ignore the affects of air resistance? One way is to realize that air resistance increases with increasing speed. Thus, as an object falls and its speed *increases,* its downward acceleration *decreases.* Under these circumstances, the object's speed will approach, as a limit, a value called its *terminal speed.* This terminal speed depends upon such things as the mass and cross-sectional area of the body. Upon reaching its terminal speed, its acceleration is zero. For a "typical" skydiver falling through the air, a typical the terminal speed is about 50 m/s (roughly 120 mph). At half its terminal speed, the skydiver's acceleration will be about $\frac{3}{4}g$. Let's take half the terminal speed as a reasonable "upper bound" beyond which we shouldn't use our constant acceleration free-fall relationships. Assuming the skydiver started from rest, (*a*) estimate how far, and for how long, the skydiver falls before we can no longer neglect air resistance. (*b*) Repeat the analysis for a ping-pong ball, which has a terminal speed of about 5.0 m/s. (*c*) What can you conclude by comparing your answers for Parts (*a*) and (*b*)?

Picture the Problem Because we're assuming that the accelerations of the skydiver and a ping-pong ball are constant to one-half their terminal velocities, we can use constant-acceleration equations to find the times required for them to reach their ″upper-bound″ velocities and their distances of fall. Let's use a coordinate system in which downward is the +*y* direction.

(*a*) Using a constant-acceleration equation, relate the upper-bound velocity to the free-fall acceleration and the time required to reach this velocity:

$$v_{\text{upper bound}} = v_0 + g\Delta t$$

or, because $v_0 = 0$,

$$v_{\text{upper bound}} = g\Delta t \Rightarrow \Delta t = \frac{v_{\text{upper bound}}}{g}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{25\,\text{m/s}}{9.81\,\text{m/s}^2} = 2.55\text{ s} \approx \boxed{2.6\,\text{s}}$$

Using a constant-acceleration equation, relate the skydiver's terminal speed to his/her acceleration and distance of fall:

$$\left(\tfrac{1}{2}v_t\right)^2 = v_0^2 + 2g\Delta y$$

or, because $v_0 = 0$,

$$\left(\tfrac{1}{2}v_t\right)^2 = 2g\Delta y \Rightarrow \Delta y = \frac{\left(\tfrac{1}{2}v_t\right)^2}{2g}$$

Substitute numerical values and evaluate Δy:

$$\Delta y = \frac{\left[\tfrac{1}{2}(50\text{ m/s})\right]^2}{2\left(9.81\text{ m/s}^2\right)} \approx \boxed{32\text{ m}}$$

(*b*) Proceed as in (*a*) with $v_{\text{upper bound}} = 5.0\text{ m/s}$ to obtain:

$$\Delta t = \frac{\tfrac{1}{2}(5.0\,\text{m/s})}{9.81\,\text{m/s}^2} = 0.255\text{ s} \approx \boxed{0.26\,\text{s}}$$

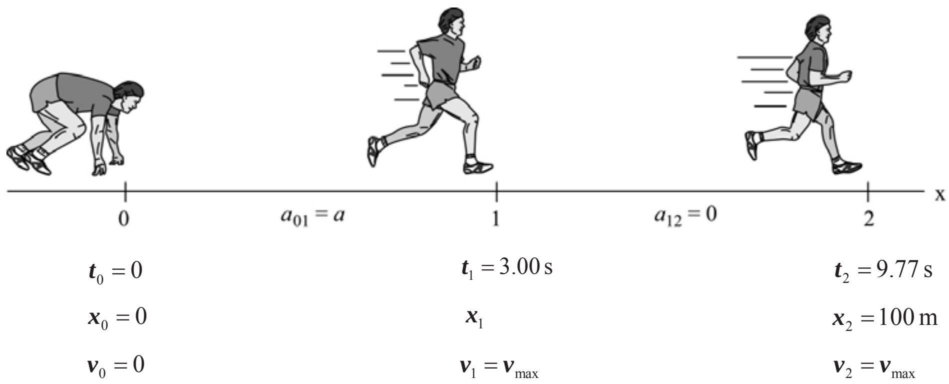
and

$$\Delta y = \frac{\left[\tfrac{1}{2}(5\text{ m/s})\right]^2}{2\left(9.81\text{ m/s}^2\right)} \approx \boxed{32\text{ cm}}$$

(*c*) The analysis of the motion of a ping-pong ball requires the inclusion of air resistance for almost any situation, whereas the analysis of the motion of the sky diver doesn't require it until the fall distances and times are considerably longer.

39 •• On June 14, 2005 Asafa Powell of the Jamaica set a world's record for the 100-m dash with a time $t = 9.77$ s. Assuming he reached his maximum speed in 3.00 s, and then maintained that speed until the finish, estimate his acceleration during the first 3.00 s.

Picture the Problem This is a constant-acceleration problem. Choose a coordinate system in which the direction Powell is running is the +*x* direction. During the first 3 s of the race his acceleration is positive and during the rest of the race it is zero. The pictorial representation summarizes what we know about Powell's race.



Express the total distance covered by Powell in terms of the distances covered in the two phases of his race:

$$100\,\text{m} = \Delta x_{01} + \Delta x_{12} \qquad (1)$$

Express the distance he runs getting to his maximum velocity:

$$\Delta x_{01} = v_0 \Delta t_{01} + \tfrac{1}{2} a_{01} (\Delta t_{01})^2 = \tfrac{1}{2} a (3\,\text{s})^2$$

The distance covered during the rest of the race at the constant maximum velocity is given by:

$$\begin{aligned}\Delta x_{12} &= v_{max} \Delta t_{12} + \tfrac{1}{2} a_{12} (\Delta t_{12})^2 \\ &= (a \Delta t_{01}) \Delta t_{12} \\ &= a(3.00\,\text{s})(6.77\,\text{s})\end{aligned}$$

Substitute for these displacements in equation (1) to obtain:

$$100\,\text{m} = \tfrac{1}{2} a (3.00\,\text{s})^2 + a(3.00\,\text{s})(6.77\,\text{s})$$

Solving for a yields:

$$a = \frac{100\,\text{m}}{\tfrac{1}{2}(3.00\,\text{s})^2 + (3.00\,\text{s})(6.77\,\text{s})} = \boxed{4.03\,\text{m/s}^2}$$

40 •• The photograph in Figure 2-38 is a short-time exposure (1/30 s) of a juggler with two tennis balls in the air. (*a*) The tennis ball near the top of its trajectory is less blurred than the lower one. Why is that? (*b*) Estimate the speed of the ball that he is just releasing from his right hand. (*c*) Determine how high the ball should have gone above the launch point and compare it to an estimate from the picture. (*Hint: You have a built-in distance scale if you assume some reasonable value for the height of the juggler*.)

Determine the Concept This is a constant-acceleration problem with $a = -g$ if we take upward to be the positive direction. At the maximum height the ball will reach, its speed will be near zero and when the ball has just been tossed in the air its speed is near its maximum value.

(*a*) Because the ball is moving slowly its blur is relatively short (i.e., there is less blurring).

(*b*) The average speed of the ball is given by:

$$v_{av} = \frac{\text{distance traveled}}{\text{elapsed time}}$$

Estimating how far the ball has traveled in 1/30 s yields:

$$v_{av} = \frac{2\text{ ball diameters}}{\frac{1}{30}\text{ s}}$$

The diameter of a tennis ball is 6.5 cm:

$$v_{av} = \frac{2(6.5\text{ cm})}{\frac{1}{30}\text{ s}} \approx \boxed{3.9\text{ m/s}}$$

(*c*) Use a constant-acceleration equation to relate the initial and final speeds of the ball to its maximum height *h*:

$$v^2 = v_0^2 + 2a_y h \Rightarrow h = \frac{v^2 - v_0^2}{2a_y}$$

or, because $v = 0$ and $a_y = g$,

$$h = -\frac{v_0^2}{2g}$$

Substitute numerical values and evaluate *h*:

$$h = -\frac{(3.9\text{ m/s})^2}{2(-9.81\text{ m/s}^2)} \approx \boxed{78\text{ cm}}$$

If we assume that the juggler is approximately 6 ft (1.8 m) tall, then our calculated value for *h* seems to be a good approximation to the height shown in the photograph.

41 •• A rough rule of thumb for determining the distance between you and a lightning strike is to start counting the seconds that elapse ("one-Mississippi, two-Mississippi, …") until you hear the thunder (sound emitted by the lightning as it rapidly heats the air around it). Assuming the speed of sound is about 750 mi/h, (*a*) estimate how far away is a lightning strike if you counted about 5 s until you heard the thunder. (*b*) Estimate the uncertainty in the distance to the strike in Part (*a*). Be sure to explain your assumptions and reasoning. (*Hint: The speed of sound depends on the air temperature and your counting is far from exact!*)

Picture the Problem We can use the relationship between distance, speed, and time to estimate the distance to the lightning strike.

(*a*) Relate the distance Δd to the lightning strike to the speed of sound in air *v* and the elapsed time Δt:

$$\Delta d = v\Delta t$$

Substitute numerical values and evaluate Δd:

$$\Delta d = \left(750\,\frac{\text{mi}}{\text{h}}\right)\left(\frac{0.3048\,\frac{\text{m}}{\text{s}}}{0.6818\,\frac{\text{mi}}{\text{h}}}\right)(5\,\text{s})$$

$$\approx \boxed{1.7\,\text{km}} \approx \boxed{1\,\text{mi}}$$

(*b*) You are probably lucky if the uncertainty in your time estimate is less than 1 s (±20%), so the uncertainty in the distance estimate is about 20% of 1.7 km or approximately 300 m. This is probably much greater than the error made by assuming *v* is constant.

Speed, Displacement, and Velocity

42 • (*a*) An electron in a television tube travels the 16-cm distance from the grid to the screen at an average speed of 4.0×10^7 m/s. How long does the trip take? (*b*) An electron in a current-carrying wire travels at an average speed of 4.0×10^{-5} m/s. How long does it take to travel 16 cm?

Picture the Problem Think of the electron as traveling in a straight line at constant speed and use the definition of average speed.

(*a*) Using its definition, express the average speed of the electron:

$$\text{Average speed} = \frac{\text{distance traveled}}{\text{time of flight}} = \frac{\Delta s}{\Delta t}$$

Solve for and evaluate the time of flight:

$$\Delta t = \frac{\Delta s}{\text{Average speed}} = \frac{0.16\ \text{m}}{4.0 \times 10^7\ \text{m/s}}$$

$$= 4.0 \times 10^{-9}\,\text{s} = \boxed{4.0\ \text{ns}}$$

(*b*) Calculate the time of flight for an electron in a 16-cm long current carrying wire similarly.

$$\Delta t = \frac{\Delta s}{\text{Average speed}} = \frac{0.16\ \text{m}}{4.0 \times 10^{-5}\ \text{m/s}}$$

$$= 4.0 \times 10^3\,\text{s} \times \frac{1\,\text{min}}{60\,\text{s}} = \boxed{67\ \text{min}}$$

43 • [SSM] A runner runs 2.5 km, in a straight line, in 9.0 min and then takes 30 min to walk back to the starting point. (*a*) What is the runner's average velocity for the first 9.0 min? (*b*) What is the average velocity for the time spent walking? (*c*) What is the average velocity for the whole trip? (*d*) What is the average speed for the whole trip?

Picture the Problem In this problem the runner is traveling in a straight line but not at constant speed - first she runs, then she walks. Let's choose a coordinate system in which her initial direction of motion is taken as the +*x* direction.

(*a*) Using the definition of average velocity, calculate the average velocity for the first 9 min:

$$v_{\text{av}} = \frac{\Delta x}{\Delta t} = \frac{2.5\ \text{km}}{9.0\ \text{min}} = \boxed{0.28\ \text{km/min}}$$

(*b*) Using the definition of average velocity, calculate her average velocity for the 30 min spent walking:

$$v_{\text{av}} = \frac{\Delta x}{\Delta t} = \frac{-2.5\ \text{km}}{30\ \text{min}}$$
$$= \boxed{-83\ \text{m/min}}$$

(*c*) Express her average velocity for the whole trip:

$$v_{\text{av}} = \frac{\Delta x_{\text{round trip}}}{\Delta t} = \frac{0}{\Delta t} = \boxed{0}$$

(*d*) Finally, express her average speed for the whole trip:

$$\text{speed}_{\text{av}} = \frac{\text{distance traveled}}{\text{elapsed time}}$$
$$= \frac{2(2.5\ \text{km})}{30\ \text{min} + 9.0\ \text{min}}$$
$$= \boxed{0.13\ \text{km/min}}$$

44 • A car travels in a straight line with an average velocity of 80 km/h for 2.5 h and then with an average velocity of 40 km/h for 1.5 h. (*a*) What is the total displacement for the 4.0-h trip? (*b*) What is the average velocity for the total trip?

Picture the Problem The car is traveling in a straight line but not at constant speed. Let the direction of motion be the +*x* direction.

(*a*) The total displacement of the car for the entire trip is the sum of the displacements for the two legs of the trip:

$$\Delta x_{\text{total}} = \Delta x_1 + \Delta x_2$$

Find the displacement for each leg of the trip:

$$\Delta x_1 = v_{av,1}\Delta t_1 = (80\ \text{km/h})(2.5\ \text{h})$$
$$= 200\,\text{km}$$

and

$$\Delta x_2 = v_{av,2}\Delta t_2 = (40\ \text{km/h})(1.5\ \text{h})$$
$$= 60.0\,\text{km}$$

Add the individual displacements to get the total displacement:

$$\Delta x_{\text{total}} = \Delta x_1 + \Delta x_2 = 200\,\text{km} + 60.0\,\text{km}$$
$$= \boxed{2.6\times10^5\,\text{m}}$$

(*b*) As long as the car continues to move in the same direction, the average velocity for the total trip is given by:

$$v_{av} = \frac{\Delta x_{total}}{\Delta t_{total}}$$

Substitute numerical values and evaluate v_{av}:

$$v_{av} = \frac{2.6\times10^5\ \text{m}}{2.5\ \text{h} + 1.5\ \text{h}} = \boxed{65\,\text{km/h}}$$

45 • One busy air route across the Atlantic Ocean is about 5500 km. The now-retired Concord, a supersonic jet capable of flying at twice the speed of sound was used to travel such routes. (*a*) Roughly how long did it take for a one-way flight? (Use 343 m/s for the speed of sound.) (*b*) Compare this time to the time taken by a subsonic jet flying at 0.90 times the speed of sound.

Picture the Problem However unlikely it may seem, imagine that both jets are flying in a straight line at constant speed and use the definition of average speed to find the flight times.

(*a*) The time of flight is the ratio of the distance traveled to the speed of the supersonic jet.

$$t_{supersonic} = \frac{s_{Atlantic}}{v_{supersonic}} = \frac{5500\ \text{km}}{2(343\,\text{m/s})(3600\,\text{s/h})} = 2.23\,\text{h} = \boxed{2.2\ \text{h}}$$

(*b*) Express the ratio of the time for the trip at supersonic speed to the time for the trip at subsonic speed and simplify to obtain:

$$\frac{t_{supersonic}}{t_{subsonic}} = \frac{\dfrac{s_{Atlantic}}{v_{supersonic}}}{\dfrac{s_{Atlantic}}{v_{subsonic}}} = \frac{v_{subsonic}}{v_{supersonic}}$$

Substitute numerical values and evaluate the ratio of the flight times:

$$\frac{t_{supersonic}}{t_{subsonic}} = \frac{(0.90)(343\,\text{m/s})}{(2)(343\,\text{m/s})} = \boxed{0.45}$$

46 •• The speed of light, designated by the universally recognized symbol *c*, has a value, to two significant figures, of 3.0×10^8 m/s. (*a*) How long does it take for light to travel from the Sun to Earth, a distance of 1.5×10^{11} m? (*b*) How long does it take light to travel from the Moon to Earth, a distance of 3.8×10^8 m?

Picture the Problem In free space, light travels in a straight line at constant speed, *c*.

(*a*) Using the definition of average speed, express the time Δt required for light to travel from the Sun to Earth:

$$\Delta t = \frac{\Delta s}{\text{average speed}}$$

where Δs is the distance from the Sun to Earth.

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{1.5\times10^{11}\ \text{m}}{3.0\times10^{8}\ \text{m/s}} = 5.0\times10^{2}\ \text{s}$$

$$\approx \boxed{8.3\,\text{min}}$$

(*b*) Proceed as in (*a*) this time using the Moon-Earth distance:

$$\Delta t = \frac{3.8\times10^{8}\ \text{m}}{3.0\times10^{8}\ \text{m/s}} \approx \boxed{1.3\,\text{s}}$$

47 • [SSM] Proxima Centauri, the closest star to us besides our own sun, is 4.1×10^{13} km from Earth. From Zorg, a planet orbiting this star, a Gregor places an order at Tony's Pizza in Hoboken, New Jersey, communicating via light signals. Tony's fastest delivery craft travels at $1.00 \times 10^{-4}c$ (see Problem 46). (*a*) How long does it take Gregor's order to reach Tony's Pizza? (*b*) How long does Gregor wait between sending the signal and receiving the pizza? If Tony's has a "1000-years-or-it's-free" delivery policy, does Gregor have to pay for the pizza?

Picture the Problem In free space, light travels in a straight line at constant speed, *c*. We can use the definition of average speed to find the elapsed times called for in this problem.

(*a*) Using the definition of average speed (equal here to the assumed constant speed of light), solve for the time Δt required to travel the distance to Proxima Centauri:

$$\Delta t = \frac{\text{distance traveled}}{\text{speed of light}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{4.1\times10^{16}\ \text{m}}{3.0\times10^{8}\ \text{m/s}} = 1.37\times10^{8}\ \text{s}$$

$$= \boxed{4.3\,\text{y}}$$

(b) The delivery time (Δt_{total}) is the sum of the time for the order to reach Hoboken and the travel time for the delivery craft to travel to Proxima Centauri:

$$\begin{aligned}\Delta t_{\text{total}} &= \Delta t_{\substack{\text{order to be}\\ \text{sent to Hoboken}}} + \Delta t_{\substack{\text{order to}\\ \text{be delivered}}}\\ &= 4.33\,y + \frac{4.1\times10^{13}\ \text{km}}{(1.00\times10^{-4})(3.0\times10^{8}\ \text{m/s})}\left(\frac{1\ \text{y}}{3.156\times10^{7}\ \text{s}}\right)\\ &= 4.3\ \text{y} + 4.3\times10^{4}\ \text{y} \approx 4.3\times10^{4}\ \text{y}\end{aligned}$$

Because 4.3×10^4 y >> 1000 y, Gregor does not have to pay.

48 • A car making a 100-km journey travels 40 km/h for the first 50 km. How fast must it go during the second 50 km to average 50 km/h?

Picture the Problem The time for the second 50 km is equal to the time for the entire journey less the time for the first 50 km. We can use this time to determine the average speed for the second 50 km interval from the definition of average speed.

Using the definition of average speed, find the time required for the total journey:

$$\Delta t_{\text{total}} = \frac{\Delta x}{v_{\text{av}}} = \frac{100\,\text{km}}{50\,\text{km/h}} = 2.0\,\text{h}$$

Find the time required for the first 50 km:

$$\Delta t_{\text{1st 50 km}} = \frac{50\,\text{km}}{40\,\text{km/h}} = 1.25\,\text{h}$$

Find the time remaining to travel the last 50 km:

$$\begin{aligned}\Delta t_{\text{2nd 50 km}} &= t_{\text{total}} - t_{\text{1st 50 km}} = 2.0\,\text{h} - 1.25\,\text{h}\\ &= 0.75\,\text{h}\end{aligned}$$

Finally, use the time remaining to travel the last 50 km to determine the average speed over this distance:

$$\begin{aligned}v_{\text{av, 2nd 50 km}} &= \frac{\Delta x_{\text{2nd 50 km}}}{\Delta t_{\text{2nd 50 km}}} = \frac{50\,\text{km}}{0.75\,\text{h}}\\ &= \boxed{67\,\text{km/h}}\end{aligned}$$

49 •• Late in ice hockey games, the team that is losing sometimes "pulls" their goalkeeper off the ice to add an additional offensive player and increase their chances of scoring. In such cases, the goalie on the opposing team might have an opportunity to score into the unguarded net that is 55.0 m away. Suppose you are the goaltender for your university team and are in just such a situation. You launch a shot (in hopes of getting your first career goal) on the frictionless ice. You hear a disappointing "clang" as the puck strikes a goalpost (instead of going in!) exactly 2.50 s later. In this case, how fast did the puck travel? You should assume 343 m/s for the speed of sound.

Picture the Problem The distance over which both the puck and the sound from the puck hitting the goalpost must travel is 55.0 m. The time between the shot being released and the sound reaching the goalie's ear can be found by expressing the total elapsed time as the sum of the elapsed times for the shot to travel 55.0 m and for the sound to travel back to you.

The total elapsed time as the sum of the elapsed times for the shot and for the sound to travel back to you :

$$\Delta t_{total} = \Delta t_{shot} + \Delta t_{sound}$$

Express the time for the shot to travel to the other net a distance Δx away:

$$\Delta t_{shot} = \frac{\Delta x}{v_{shot}}$$

Express the time for the sound to travel a distance Δx back to you:

$$\Delta t_{sound} = \frac{\Delta x}{v_{sound}}$$

Substitute in the expression for Δt_{total} to obtain:

$$\Delta t_{total} = \frac{\Delta x}{v_{shot}} + \frac{\Delta x}{v_{sound}}$$

Solving this equation for v_{shot} yields:

$$v_{shot} = \frac{v_{sound}\Delta x}{v_{sound}\Delta t_{total} - \Delta x}$$

Substitute numerical values and evaluate v_{shot} :

$$v_{shot} = \frac{(343\text{ m/s})(55.0\text{ m})}{(343\text{ m/s})(2.50\text{ s}) - 55.0\text{ m}} = \boxed{23.5\text{ m/s}}$$

50 •• Cosmonaut Andrei, your co-worker at the International Space Station, tosses a banana at you with a speed of 15 m/s. At exactly the same instant, you fling a scoop of ice cream at Andrei along exactly the same path. The collision between banana and ice cream produces a banana split 7.2 m from your location 1.2 s after the banana and ice cream were launched. (*a*) How fast did you toss the ice cream? (*b*) How far were you from Andrei when you tossed the ice cream? (Neglect any effects due to gravity.)

Picture the Problem Let the subscript b refer to the banana and the subscript ic refer to the ice cream. Then the distance covered by the ice cream before collision is given by $\Delta x_{ic} = v_{ic}\Delta t$ and the distance covered by the banana is $\Delta x_b = v_b\Delta t$. The distance between you and Andrei is then the sum of these distances: $\Delta x_{tot} = \Delta x_{ic} + \Delta x_b$.

(*a*) The speed of the ice cream is given by:

$$v_{ic} = \frac{\Delta x_{ic}}{\Delta t}$$

where Δt is the time-to-collision.

Substitute numerical values and evaluate v_{ic}:

$$v_{ic} = \frac{7.2\text{ m}}{1.2\text{ s}} = \boxed{6.0\text{ m/s}}$$

(*b*) Express the distance between yourself and Andrei as the sum of the distances the ice cream and the banana travel:

$$\Delta \boldsymbol{x}_{\text{total}} = \Delta \boldsymbol{x}_{\text{ic}} + \Delta \boldsymbol{x}_{\text{b}}$$

Because $\Delta x_{\text{b}} = v_{\text{b}} \Delta t$:

$$\Delta x_{\text{total}} = \Delta x_{\text{ic}} + v_{\text{b}} \Delta t$$

Substitute numerical values and evaluate Δx_{total}:

$$\Delta x_{\text{total}} = 7.2\text{ m} + (15\text{ m/s})(1.2\text{ s}) = \boxed{25\text{ m}}$$

51 •• Figure 2-39 shows the position of a particle as a function of time. Find the average velocities for the time intervals *a*, *b*, *c*, and *d* indicated in the figure.

Picture the Problem The average velocity in a time interval is defined as the displacement divided by the time elapsed; that is $v_{\text{av}} = \Delta x / \Delta t$.

(*a*) $\Delta x_a = 0$

$$v_{\text{av}} = \boxed{0}$$

(*b*) $\Delta x_b = 1$ m and $\Delta t_b = 3$ s

$$v_{\text{av}} = \boxed{0.3\text{ m/s}}$$

(*c*) $\Delta x_c = -6$ m and $\Delta t_c = 3$ s

$$v_{\text{av}} = \boxed{-2\text{ m/s}}$$

(*d*) $\Delta x_d = 3$ m and $\Delta t_d = 3$ s

$$v_{\text{av}} = \boxed{1\text{ m/s}}$$

52 •• It has been found that, on average, galaxies are moving away from Earth at a speed that is proportional to their distance from Earth. This discovery is known as Hubble's law, named for its discoverer, astrophysicist Sir Edwin Hubble. He found that the recessional speed v of a galaxy a distance r from Earth is given by $v = Hr$, where $H = 1.58 \times 10^{-18}\text{ s}^{-1}$ is called the Hubble constant. What are the expected recessional speeds of galaxies (*a*) 5.00×10^{22} m from Earth and (*b*) 2.00×10^{25} m from Earth? (*c*) If the galaxies at each of these distances had traveled at their expected recessional speeds, how long ago would they have been at our location?

Picture the Problem In free space, light travels in a straight line at constant speed *c*. We can use Hubble's law to find the speed of the two planets.

(*a*) Using Hubble's law, calculate the speed of the first galaxy:

$$v_{\text{a}} = (5.00 \times 10^{22}\text{ m})(1.58 \times 10^{-18}\text{ s}^{-1}) = \boxed{7.90 \times 10^{4}\text{ m/s}}$$

(*b*) Using Hubble's law, calculate the speed of the second galaxy:

$$v_b = (2.00\times10^{25}\text{ m})(1.58\times10^{-18}\text{ s}^{-1}) = \boxed{3.16\times10^{7}\text{ m/s}}$$

(*c*) Using the relationship between distance, speed, and time for both galaxies, express how long ago Δt they were both located at the same place as Earth:

$$\Delta t = \frac{r}{v} = \frac{r}{rH} = \frac{1}{H}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = 6.33\times10^{17}\text{ s} \approx \boxed{20\times10^{9}\text{ y}}$$

53 •• [SSM] The cheetah can run as fast as 113 km/h, the falcon can fly as fast as 161 km/h, and the sailfish can swim as fast as 105 km/h. The three of them run a relay with each covering a distance *L* at maximum speed. What is the average speed of this relay team for the entire relay? Compare this average speed with the numerical average of the three individual speeds. Explain carefully why the average speed of the relay team is *not* equal to the numerical average of the three individual speeds.

Picture the Problem We can find the average speed of the relay team from the definition of average speed.

Using its definition, relate the average speed to the total distance traveled and the elapsed time:

$$v_{av} = \frac{\text{distance traveled}}{\text{elapsed time}}$$

Express the time required for each animal to travel a distance L:

$$t_{cheetah} = \frac{L}{v_{cheetah}},\ t_{falcon} = \frac{L}{v_{falcon}}$$

and

$$t_{sailfish} = \frac{L}{v_{sailfish}}$$

Express the total time Δt:

$$\Delta t = L\left(\frac{1}{v_{cheetah}} + \frac{1}{v_{falcon}} + \frac{1}{v_{sailfish}}\right)$$

Use the total distance traveled by the relay team and the elapsed time to calculate the average speed:

$$v_{av} = \frac{3L}{L\left(\frac{1}{113\,\text{km/h}} + \frac{1}{161\,\text{km/h}} + \frac{1}{105\,\text{km/h}}\right)} = 122.03\,\text{km/h} = \boxed{122\,\text{km/h}}$$

Calculating the average of the three speeds yields:

$$\text{Average}_{\text{three speeds}} = \frac{113\,\text{km/h} + 161\,\text{km/h} + 105\,\text{km/h}}{3} = 126.33\,\text{km/h} = 126\,\text{km/h}$$
$$= \boxed{1.04 v_{\text{av}}}$$

The average speed of the relay team is *not* equal to the numerical average of the three individual speeds because the ″runners″ did not run for the same interval of time. The average speed would be equal to one-third the sum of the three speeds if the three speeds were each maintained for the same length of time instead of for the same distance.

54 •• Two cars are traveling along a straight road. Car A maintains a constant speed of 80 km/h and car B maintains a constant speed of 110 km/h. At $t = 0$, car B is 45 km behind car A. (*a*) How much farther will car A travel before car B overtakes it? (*b*) How much ahead of A will B be 30 s after it overtakes A?

Picture the Problem Let the position of car A at $t = 0$ be the origin of our coordinate system. Then we can use a constant-acceleration equation to express the positions of both cars as functions of time and equate these expressions to determine the time at which car A is overtaken by car B.

(*a*) Car B overtakes car A when their *x* coordinates are the same:

$$x_A(t) = x_B(t) \qquad (1)$$

Using a constant-acceleration equation with $a = 0$, express the position of car A as a function of time:

$$x_A(t) = x_{0A} + v_A t$$

where x_{0A} is the position of car A at $t = 0$.

Because we've let car A be at the origin at $t = 0$:

$$x_A(t) = v_A t \qquad (2)$$

Using a constant-acceleration equation, express the position of car B as a function of time:

$$x_B(t) = x_{0B} + v_B t$$

where x_{0B} is the position of car B at $t = 0$.

Substitute for $x_A(t)$ and $x_B(t)$ in equation (1) to obtain:

$$v_A t = x_{0B} + v_B t \Rightarrow t = \frac{x_{0B}}{v_A - v_B}$$

Substitute numerical values and evaluate the time *t* at which car B overtakes car A:

$$t = \frac{-45\,\text{km}}{80\,\text{km/h} - 110\,\text{km/h}} = 1.50\,\text{h}$$

Now we can evaluate equation (2) at $t = 1.50$ h to obtain:

$$x_A(1.50\text{ h}) = \left(80\,\frac{\text{km}}{\text{h}}\right)(1.50\text{ h}) = 120\text{ km}$$
$$= \boxed{1.2\times10^5\text{ m}}$$

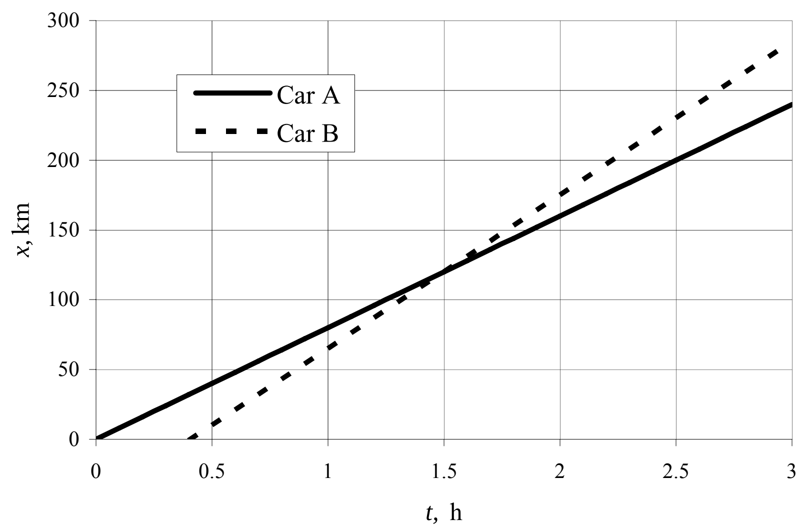
(*b*) The separation of the cars as a function of time is given by:

$$\Delta x(t) = x_B(t) - x_A(t) = x_{0B} - v_B t - v_A t$$

Substitute numerical values and evaluate $\Delta x(1.50\text{ h} + 30\text{ s}) = \Delta x\left(1.50\text{ h} + \tfrac{1}{120}\text{ h}\right)$ to obtain:

$$\Delta x\left(1.50\text{ h} + \tfrac{1}{120}\text{ h}\right) = -45\text{ km} + \left(110\,\frac{\text{km}}{\text{h}} - 80\,\frac{\text{km}}{\text{h}}\right)\left(1.50\text{ h} + \tfrac{1}{120}\text{ h}\right) = \boxed{0.25\text{ km}}$$

Remarks: One can use a graphing calculator or a spreadsheet program to solve this problem. A spreadsheet program was used to plot the following graph:



Note that this graph confirms our result that the cars are at the same location at t = 1.5 h.

55 •• **[SSM]** A car traveling at a constant speed of 20 m/s passes an intersection at time $t = 0$. A second car traveling at a constant speed of 30 m/s in the same direction passes the same intersection 5.0 s later. (*a*) Sketch the position functions $x_1(t)$ and $x_2(t)$ for the two cars for the interval $0 \le t \le 20$ s. (*b*) Determine when the second car will overtake the first. (*c*) How far from the intersection will the two cars be when they pull even? (*d*) Where is the first car when the second car passes the intersection?

Picture the Problem One way to solve this problem is by using a graphing calculator to plot the positions of each car as a function of time. Plotting these positions as functions of time allows us to visualize the motion of the two cars

relative to the (fixed) ground. More importantly, it allows us to see the motion of the two cars relative to each other. We can, for example, tell how far apart the cars are at any given time by determining the length of a vertical line segment from one curve to the other.

(*a*) Letting the origin of our coordinate system be at the intersection, the position of the slower car, $x_1(t)$, is given by:

$x_1(t) = 20t$
where x_1 is in meters if t is in seconds.

Because the faster car is also moving at a constant speed, we know that the position of this car is given by a function of the form:

$x_2(t) = 30t + b$

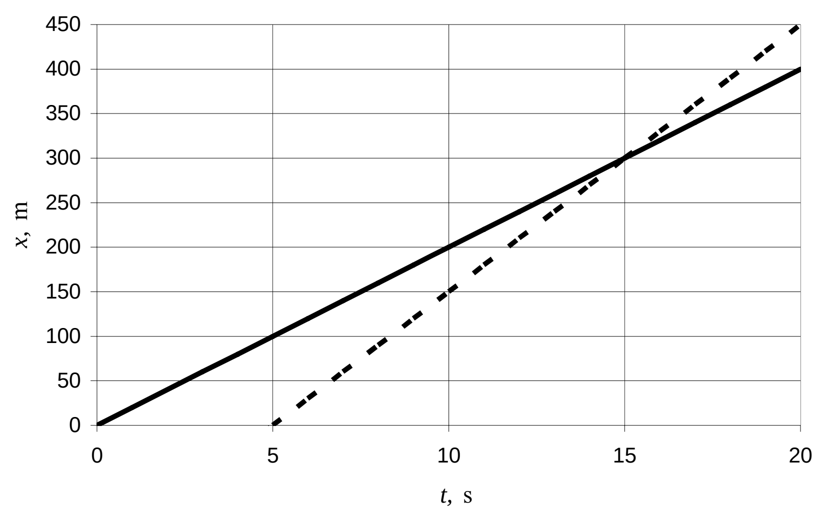
We know that when $t = 5.0$ s, this second car is at the intersection (that is, $x_2(5.0\text{ s}) = 0$). Using this information, you can convince yourself that:

$b = -150$ m

Thus, the position of the faster car is given by:

$x_2(t) = 30t - 150$

One can use a graphing calculator, graphing paper, or a spreadsheet to obtain the following graphs of $x_1(t)$ (the solid line) and $x_2(t)$ (the dashed line):



(*b*) Use the time coordinate of the intersection of the two lines to determine the time at which the second car overtakes the first:

From the intersection of the two lines, one can see that the second car will "overtake" (catch up to) the first car at $\boxed{t = 15\text{ s.}}$

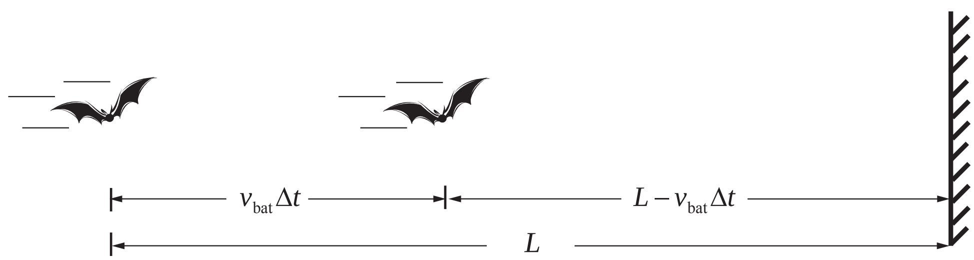
(*c*) Use the position coordinate of the intersection of the two lines to determine the distance from the intersection at which the second car catches up to the first car:

From the intersection of the two lines, one can see that the distance from the intersection is $\boxed{300\text{ m.}}$

(*d*) Draw a vertical line from $t = 5$ s to the solid line and then read the position coordinate of the intersection of the vertical line and the solid line to determine the position of the first car when the second car went through the intersection. From the graph, when the second car passes the intersection, the first car was $\boxed{100\text{ m ahead.}}$

56 •• Bats use echolocation to determine their distance from objects they cannot easily see in the dark. The time between the emission of high-frequency sound pulse (a click) and the detection of its echo is used to determine such distances. A bat, flying at a constant speed of 19.5 m/s in a straight line toward a vertical cave wall, makes a single clicking noise and hears the echo 0.15 s later. Assuming that she continued flying at her original speed, how close was she to the wall when she received the echo? Assume a speed of 343 m/s for the speed of sound.

Picture the Problem The sound emitted by the bat travels at v_{sound} and during the time interval Δt during which the sound travels to the wall (a distance L from the bat's initial position) and back to the bat, the bat travels a distance of $\Delta x_{\text{bat}} = v_{\text{bat}}\Delta t$, where v_{bat} is the bat's flying speed. The distance of the bat from the wall when she received the echo of her click is $\Delta x_{\text{away}} = L - v_{\text{bat}}\Delta t$ where $\Delta t = \Delta t_{\text{to wall}} + \Delta t_{\substack{\text{back}\\\text{to bat}}}$.



Express the distance of the bat from the wall of the cave when it hears the echo of its click:

$$\Delta x_{\text{away}} = L - v_{\text{bat}}\Delta t \qquad (1)$$

The elapsed time between the bat clicking and hearing the sound is:

$$\Delta t = \Delta t_{\text{to wall}} + \Delta t_{\substack{\text{back}\\\text{to bat}}}$$

Substituting for $\Delta t_{\text{to wall}}$ and $\Delta t_{\substack{\text{back}\\ \text{to bat}}}$ gives:

$$\Delta t = \frac{L}{v_{\text{sound}}} + \frac{L - v_{\text{bat}}\Delta t}{v_{\text{sound}}}$$

Solving for L yields:

$$L = \tfrac{1}{2}\left(v_{\text{sound}} + v_{\text{bat}}\right)\Delta t$$

Substitute for L in equation (1) and simplify to obtain:

$$\Delta x_{\text{away}} = \tfrac{1}{2}\left(v_{\text{sound}} + v_{\text{bat}}\right)\Delta t - v_{\text{bat}}\Delta t = \tfrac{1}{2}\left(v_{\text{sound}} - v_{\text{bat}}\right)\Delta t$$

Substitute numerical values and evaluate Δx_{away}:

$$\Delta x_{\text{away}} = \tfrac{1}{2}\left(343\ \text{m/s} - 19.5\ \text{m/s}\right)\left(0.15\ \text{s}\right) = \boxed{24\ \text{m}}$$

57 ••• A submarine can use *sonar* (sound traveling through water) to determine its distance from other objects. The time between the emission of a sound pulse (a ″ping″) and the detection of its echo can be used to determine such distances. Alternatively, by measuring the time between *successive* echo receptions of a *regularly timed set* of pings, the submarine's *speed* may be determined by comparing the time between echoes to the time between pings. Assume you are the sonar operator in a submarine traveling at a constant velocity underwater. Your boat is in the eastern Mediterranean Sea, where the speed of sound is known to be 1522 m/s. If you send out pings every 2.000 s, and your apparatus receives echoes reflected from an undersea cliff every 1.980 s, how fast is your submarine traveling?

Picture the Problem Both the pulses sent out by the submarine and the pulses returning from the sea-wall are traveling at 1522 m/s. Consequently, we can determine the distance in water between two successive echo (or emitted) pulses of sound which were emitted with a time interval $\Delta t_{\text{emitted}}$ between them. The actual distance in the seawater between the echoed pulses is given by $\Delta x = v_{\text{sound}}\Delta t_{\text{emitted}}$. We need to find the time $\Delta t_{\text{received}}$ between successive pulses received by the submarine. We start our ″clock″, as it were, when the submarine passes one of two successive pulses that approach it, separated by the distance Δx. After passing the first pulse, the next sound pulse moves toward the submarine at v_{sound} and the submarine moves toward the pulse at speed v_{sub}. The distance between successive pulses Δx may be divided into Δx_{sub} and Δx_{sound}, which are equal to $v_{\text{sub}}\Delta t_{\text{received}}$ and $v_{\text{sub}}\Delta t_{\text{received}}$, respectively.

The distance between successive pulses is given by:

$$\Delta x = \Delta x_{\text{sub}} + \Delta x_{\text{received}}$$

Substituting for all three terms in this equation yields:

$$v_{\text{sound}}\Delta t_{\text{emitted}} = v_{\text{sub}}\Delta t_{\text{received}} + v_{\text{sound}}\Delta t_{\text{received}}$$

Solve for v_{sub} to obtain:

$$v_{sub} = \frac{v_{sound}\left(\Delta t_{emitted} - \Delta t_{received}\right)}{\Delta t_{received}}$$

Substitute numerical values and evaluate v_{sub}:

$$v_{sub} = \frac{(1522\text{ m/s})(2.000\text{ s} - 1.980\text{ s})}{2.000\text{ s}} = \boxed{15\text{ m/s}}$$

Acceleration

58 • A sports car accelerates in third gear from 48.3 km/h (about 30 mi/h) to 80.5 km/h (about 50 mi/h) in 3.70 s. (*a*) What is the average acceleration of this car in m/s^2? (*b*) If the car maintained this acceleration, how fast would it be moving one second later?

Picture the Problem In Part (*a*), we can apply the definition of average acceleration to find a_{av}. In Part (*b*), we can find the change in the car's velocity in one second and add this change to its velocity at the beginning of the interval to find its speed one second later.

(*a*) The definition of average acceleration is:

$$a_{av} = \frac{\Delta v}{\Delta t}$$

Substitute numerical values and evaluate a_{av}:

$$a_{av} = \frac{80.5\text{ km/h} - 48.3\text{ km/h}}{3.70\text{ s}} = 8.70\frac{\text{km}}{\text{h}\cdot\text{s}}$$

Convert a_{av} to m/s^2:

$$a_{av} = \left(8.70\times 10^3\frac{\text{m}}{\text{h}\cdot\text{s}}\right)\left(\frac{1\text{ h}}{3600\text{ s}}\right) = \boxed{2.42\text{ m/s}^2}$$

(*b*) Express the speed of the car at the end of 4.7 s:

$$v(4.7\text{ s}) = v(3.70\text{ s}) + \Delta v_{1\text{s}} = 80.5\text{ km/h} + \Delta v_{1\text{s}}$$

Find the change in the speed of the car in 1.00 s:

$$\Delta v = a_{av}\Delta t = \left(8.70\frac{\text{km}}{\text{h}\cdot\text{s}}\right)(1.00\text{ s}) = 8.70\text{ km/h}$$

Substitute and evaluate $v(4.7\text{ s})$:

$$v(4.7\text{ s}) = 80.5\text{ km/h} + 8.7\text{ km/h} = \boxed{89.2\text{ km/h}}$$

59 • **[SSM]** An object is moving along the x axis. At $t = 5.0$ s, the object is at $x = +3.0$ m and has a velocity of +5.0 m/s. At $t = 8.0$ s, it is at $x = +9.0$ m and its velocity is –1.0 m/s. Find its average acceleration during the time interval $5.0\text{ s} \le t \le 8.0\text{ s}$.

Picture the Problem We can find the change in velocity and the elapsed time from the given information and then use the definition of average acceleration.

The average acceleration is defined as the change in velocity divided by the change in time:

$$a_{\text{av}} = \frac{\Delta v}{\Delta t}$$

Substitute numerical values and evaluate a_{av}:

$$a_{\text{av}} = \frac{(-1.0\text{ m/s}) - (5.0\text{ m/s})}{(8.0\text{ s}) - (5.0\text{ s})} = \boxed{-2.0\text{ m/s}^2}$$

60 •• A particle moves along the x axis with velocity $v_x = (8.0\text{ m/s}^2)\,t - 7.0\text{ m/s}$. (*a*) Find the average acceleration for two different one-second intervals, one beginning at $t = 3.0$ s and the other beginning at $t = 4.0$ s. (*b*) Sketch v_x versus t over the interval $0 < t < 10$ s. (*c*) How do the instantaneous accelerations at the middle of each of the two time intervals specified in Part (*a*) compare to the average accelerations found in Part (*a*)? Explain.

Picture the Problem The important concept here is the difference between average acceleration and instantaneous acceleration.

(*a*) The average acceleration is defined as the change in velocity divided by the change in time:

$$a_{\text{av}} = \frac{\Delta v}{\Delta t}$$

Determine v_x at $t = 3.0$ s, $t = 4.0$ s, and $t = 5.0$ s:

$$v_x(3.0\text{ s}) = (8.0\text{ m/s}^2)(3.0\text{ s}) - 7.0\text{ m/s} = 17\text{ m/s}$$

$$v_x(4.0\text{ s}) = (8.0\text{ m/s}^2)(4.0\text{ s}) - 7.0\text{ m/s} = 25\text{ m/s}$$

$$v_x(5.0\text{ s}) = (8.0\text{ m/s}^2)(5.0\text{ s}) - 7.0\text{ m/s} = 33\text{ m/s}$$

Find a_{av} for the two 1-s intervals:

$$a_{\text{av, 3.0 s to 4.0 s}} = \frac{25\text{ m/s} - 17\text{ m/s}}{1.0\text{ s}} = 8.0\text{ m/s}^2$$

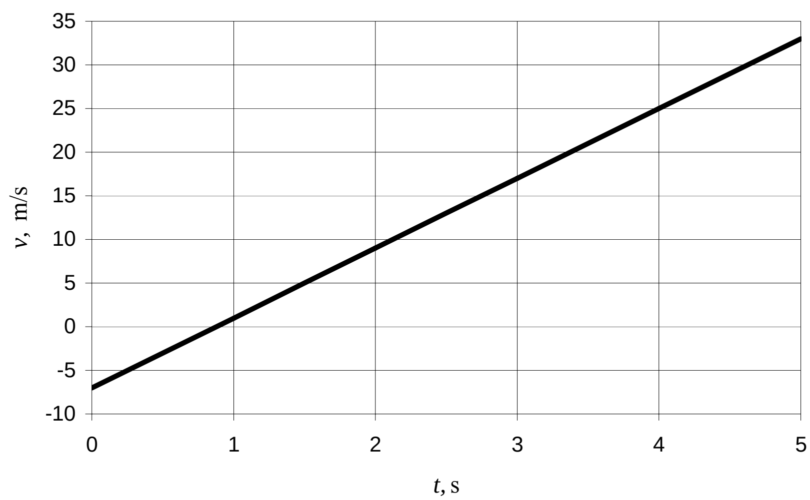
and

$$a_{\text{av, 4.0 s to 5.0 s}} = \frac{33\text{ m/s} - 25\text{ m/s}}{1.0\text{ s}} = 8.0\text{ m/s}^2$$

The instantaneous acceleration is defined as the time derivative of the velocity or the slope of the velocity- versus-time curve:

$$a_x = \frac{dv_x}{dt} = \frac{d}{dt}\left[\left(8.0\text{ m/s}^2\right)t - 7.0\text{ m/s}\right] = \boxed{8.0\text{ m/s}^2}$$

(b) The given function and a spreadsheet program were used to plot the following graph of v-versus-t:



(c) Because the particle's speed varies linearly with time, these accelerations are the same.

61 •• [SSM] The position of a certain particle depends on time according to the equation $x(t) = t^2 - 5.0t + 1.0$, where x is in meters if t is in seconds. (a) Find the displacement and average velocity for the interval $3.0\text{ s} \le t \le 4.0\text{ s}$. ($b$) Find the general formula for the displacement for the time interval from t to $t + \Delta t$. (c) Use the limiting process to obtain the instantaneous velocity for any time t.

Picture the Problem We can closely approximate the instantaneous velocity by the average velocity in the limit as the time interval of the average becomes small. This is important because all we can ever obtain from any measurement is the average velocity, v_{av}, which we use to approximate the instantaneous velocity v.

(*a*) The displacement of the particle during the interval 3.0 s ≤ t ≤ 4.0 s is given by:

$$\Delta x = x(4.0\ \text{s}) - x(3.0\ \text{s}) \qquad (1)$$

The average velocity is given by:

$$v_{\text{av}} = \frac{\Delta x}{\Delta t} \qquad (2)$$

Find $x(4.0\ \text{s})$ and $x(3.0\ \text{s})$:

$x(4.0\ \text{s}) = (4.0)^2 - 5(4.0) + 1 = -3.0\ \text{m}$
and
$x(3.0\ \text{s}) = (3.0)^2 - 5(3.0) + 1 = -5.0\ \text{m}$

Substitute numerical values in equation (1) and evaluate Δx:

$$\Delta x = (-3.0\ \text{m}) - (-5.0\ \text{m}) = \boxed{2.0\ \text{m}}$$

Substitute numerical values in equation (2) and evaluate v_{av}:

$$v_{\text{av}} = \frac{2.0\ \text{m}}{1.0\ \text{s}} = \boxed{2.0\ \text{m/s}}$$

(*b*) Find $x(t + \Delta t)$:

$$\begin{aligned} x(t+\Delta t) &= (t+\Delta t)^2 - 5(t+\Delta t) + 1 \\ &= (t^2 + 2t\Delta t + (\Delta t)^2) \\ &\quad - 5(t+\Delta t) + 1 \end{aligned}$$

Express $x(t + \Delta t) - x(t) = \Delta x$:

$$\Delta x = \boxed{(2t-5)\Delta t + (\Delta t)^2}$$

where Δx is in meters if t is in seconds.

(*c*) From (*b*) find $\Delta x/\Delta t$ as $\Delta t \to 0$:

$$\begin{aligned} \frac{\Delta x}{\Delta t} &= \frac{(2t-5)\Delta t + (\Delta t)^2}{\Delta t} \\ &= 2t - 5 + \Delta t \end{aligned}$$

and

$$v = \lim_{\Delta t \to 0}(\Delta x/\Delta t) = \boxed{2t-5}$$

where v is in m/s if t is in seconds.

Alternatively, we can take the derivative of $x(t)$ with respect to time to obtain the instantaneous velocity.

$$\begin{aligned} v(t) &= \frac{dx(t)}{dt} = \frac{d}{dt}\left(at^2 + bt + 1\right) \\ &= 2at + b \\ &= \boxed{2t - 5} \end{aligned}$$

62 •• The position of an object as a function of time is given by $x = At^2 - Bt + C$, where $A = 8.0\ \text{m/s}^2$, $B = 6.0\ \text{m/s}$, and $C = 4.0\ \text{m}$. Find the instantaneous velocity and acceleration as functions of time.

Picture the Problem The instantaneous velocity is dx/dt and the acceleration is dv/dt.

Using the definitions of instantaneous velocity and acceleration, determine v and a:

$$v = \frac{dx}{dt} = \frac{d}{dt}\left[At^2 - Bt + C\right] = 2At - B$$

and

$$a = \frac{dv}{dt} = \frac{d}{dt}\left[2At - B\right] = 2A$$

Substitute numerical values for A and B and evaluate v and a:

$$v = 2\left(8.0\ \text{m/s}^2\right)t - 6.0\ \text{m/s}$$
$$= \boxed{\left(16\ \text{m/s}^2\right)t - 6.0\ \text{m/s}}$$

and

$$a = 2\left(8.0\ \text{m/s}^2\right) = \boxed{16\ \text{m/s}^2}$$

63 ••• The one-dimensional motion of a particle is plotted in Figure 2-40. (*a*) What is the average acceleration in each of the intervals *AB*, *BC*, and *CE*? (*b*) How far is the particle from its starting point after 10 s? (*c*) Sketch the displacement of the particle as a function of time; label the instants A, B, C, D, and E on your graph. (*d*) At what time is the particle traveling most slowly?

Picture the Problem We can use the definition of average acceleration ($a_{av} = \Delta v/\Delta t$) to find a_{av} for the three intervals of constant acceleration shown on the graph.

(*a*) Using the definition of average acceleration, find a_{av} for the interval AB:

$$a_{\text{av, AB}} = \frac{15.0\ \text{m/s} - 5.0\ \text{m/s}}{3.0\ \text{s}} = \boxed{3.3\ \text{m/s}^2}$$

Find a_{av} for the interval BC:

$$a_{\text{av, BC}} = \frac{15.0\ \text{m/s} - 15.0\ \text{m/s}}{3.0\ \text{s}} = \boxed{0}$$

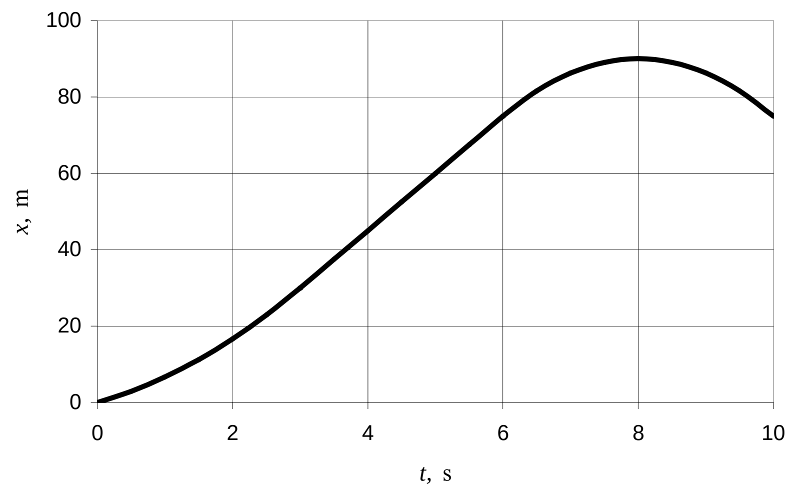
Find a_{av} for the interval CE:

$$a_{\text{av, CE}} = \frac{-15.0\ \text{m/s} - 15.0\ \text{m/s}}{4.0\ \text{s}}$$
$$= \boxed{-7.5\ \text{m/s}^2}$$

(*b*) Use the formulas for the areas of trapezoids and triangles to find the area under the graph of v as a function of t.

$$\begin{aligned}\Delta x &= (\Delta x)_{\text{A}\to\text{B}} + (\Delta x)_{\text{B}\to\text{C}} + (\Delta x)_{\text{C}\to\text{D}} + (\Delta x)_{\text{D}\to\text{E}}\\ &= \tfrac{1}{2}(5.0\ \text{m/s} + 15.0\ \text{m/s})(3.0\ \text{s}) + (15.0\ \text{m/s})(3.0\ \text{s}) + \tfrac{1}{2}(15.0\ \text{m/s})(2.0\ \text{s})\\ &\qquad + \tfrac{1}{2}(-15.0\ \text{m/s})(2.0\ \text{s})\\ &= \boxed{75\ \text{m}}\end{aligned}$$

(*c*) The graph of displacement, *x*, as a function of time, *t*, is shown in the following figure. In the region from B to C the velocity is constant so the *x*- versus-*t* curve is a straight line.



(*d*) Reading directly from the figure, we can find the time when the particle is moving the slowest. At point D, $t = 8$ s, the graph crosses the time axis; therefore $v = 0$.

Constant Acceleration and Free-Fall

64 • An object projected vertically upward with initial speed v_0 attains a maximum height h above its launch point. Another object projected up with initial speed $2v_0$ from the same height will attain a maximum height of (*a*) $4h$, (*b*) $3h$, (*c*) $2h$, (*d*) h. (Air resistance is negligible.)

Picture the Problem Because the acceleration is constant ($-g$) we can use a constant-acceleration equation to find the height of the projectile.

Using a constant-acceleration equation, express the height of the object as a function of its initial speed, the acceleration due to gravity, and its displacement:

$$v^2 = v_0^2 - 2g\Delta y$$

or, because $v(h) = 0$,

$$0 = v_0^2 - 2gh \Rightarrow h = \frac{v_0^2}{2g}$$

Express the ratio of the maximum height of the second object to that of the first object and simplify to obtain:

$$\frac{h_{\text{2nd object}}}{h_{\text{1st object}}} = \frac{\dfrac{(2v_0)^2}{2g}}{\dfrac{(v_0)^2}{2g}} = 4$$

Solving for $h_{\text{2nd object}}$ yields: $h_{\text{2nd object}} = 4h \Rightarrow (a)$ is correct.

65 •• A car traveling along the x axis starts from rest at x = 50 m and accelerates at a constant rate of 8.0 m/s^2. (a) How fast is it going after 10 s? (b) How far has it gone after 10 s? (c) What is its average velocity for the interval $0 \le t \le 10$ s?

Picture the Problem Because the acceleration of the car is constant we can use constant-acceleration equations to describe its motion.

(a) Using a constant-acceleration equation, relate the velocity to the acceleration and the time:

$$v = v_0 + at$$

Substitute numerical values and evaluate v:

$$v = 0 + \left(8.0\,\frac{\text{m}}{\text{s}^2}\right)(10\,\text{s}) = \boxed{80\,\text{m/s}}$$

(b) Using a constant-acceleration equation, relate the displacement to the acceleration and the time:

$$\Delta x = x - x_0 = v_0 t + \frac{a}{2}t^2$$

Substitute numerical values and evaluate Δx:

$$\Delta \boldsymbol{x} = \frac{1}{2}\left(8.0\,\frac{\text{m}}{\text{s}^2}\right)(10\,\text{s})^2 = \boxed{0.40\,\text{km}}$$

(c) Use the definition of v_{av} :

$$v_{\text{av}} = \frac{\Delta x}{\Delta t} = \frac{400\,\text{m}}{10\,\text{s}} = \boxed{40\,\text{m/s}}$$

Remarks: Because the area under a velocity-versus-time graph is the displacement of the object, we could solve this problem graphically.

66 • An object traveling along the x axis with an initial velocity of +5.0 m/s has a constant acceleration of +2.0 m/s^2. When its speed is 15 m/s, how far has it traveled?

Picture the Problem Because the acceleration of the object is constant we can use constant-acceleration equations to describe its motion.

Using a constant-acceleration equation, relate the speed of the object to its acceleration and displacement:

$$v^2 = v_0^2 + 2a\,\Delta x \Rightarrow \Delta x = \frac{v^2 - v_0^2}{2a}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{\left(15^2 - 5.0^2\right)\text{m}^2/\text{s}^2}{2\left(2.0\,\text{m/s}^2\right)} = \boxed{50\,\text{m}}$$

67 • **[SSM]** An object traveling along the x axis at constant acceleration has a velocity of +10 m/s when it is at $x = 6.0$ m and of +15 m/s when it is at $x = 10$ m. What is its acceleration?

Picture the Problem Because the acceleration of the object is constant we can use constant-acceleration equations to describe its motion.

Using a constant-acceleration equation, relate the velocity to the acceleration and the displacement:

$$v^2 = v_0^2 + 2a\Delta x \Rightarrow a = \frac{v^2 - v_0^2}{2\Delta x}$$

Substitute numerical values and evaluate a:

$$a = \frac{\left(15^2 - 10^2\right)\mathrm{m^2/s^2}}{2\left(10\,\mathrm{m} - 6.0\,\mathrm{m}\right)} = \boxed{16\,\mathrm{m/s^2}}$$

68 • The speed of an object traveling along the x axis increases at the constant rate of +4.0 m/s each second. At $t = 0.0$ s, its velocity is +1.0 m/s and its position is +7.0 m. How fast is it moving when its position is +8.0 m, and how much time has elapsed from the start at $t = 0.0$ s?

Picture the Problem Because the acceleration of the object is constant we can use constant-acceleration equations to describe its motion.

Using a constant-acceleration equation, relate the velocity to the acceleration and the displacement:

$$v^2 = v_0^2 + 2a\Delta x \Rightarrow v = \sqrt{v_0^2 + 2a\Delta x}$$

Substitute numerical values and evaluate v to obtain:

$$v = \sqrt{\left(1.0\,\mathrm{m/s}\right)^2 + 2\left(4.0\,\mathrm{m/s^2}\right)\left(8.0\,\mathrm{m} - 7.0\,\mathrm{m}\right)} = \boxed{3.0\,\mathrm{m/s}}$$

From the definition of average acceleration we have:

$$\Delta t = \frac{\Delta v}{a_{\mathrm{av}}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{3.0\,\mathrm{m/s} - 1.0\,\mathrm{m/s}}{4.0\,\mathrm{m/s^2}} = \boxed{0.50\,\mathrm{s}}$$

69 •• A ball is launched directly upward from ground level with an initial speed of 20 m/s. (Air resistance is negligible.) (*a*) How long is the ball in the air? (*b*) What is the greatest height reached by the ball? (*c*) How many seconds after launch is the ball 15 m above the release point?

Picture the Problem In the absence of air resistance, the ball experiences constant acceleration. Choose a coordinate system with the origin at the point of release and the positive direction upward.

(*a*) Using a constant-acceleration equation, relate the displacement of the ball to the acceleration and the time:

$$\Delta y = v_0 t + \tfrac{1}{2}at^2$$

Setting $\Delta y = 0$ (the displacement for a round trip), solve for the time required for the ball to return to its starting position:

$$0 = v_0 t_{\text{roundtrip}} + \tfrac{1}{2}at^2_{\substack{\text{round}\\\text{trip}}}$$

and

$$t_{\substack{\text{round}\\\text{trip}}} = \frac{2v_0}{g}$$

Substitute numerical values and evaluate $t_{\substack{\text{round}\\\text{trip}}}$:

$$t_{\substack{\text{round}\\\text{trip}}} = \frac{2(20\,\text{m/s})}{9.81\,\text{m/s}^2} = \boxed{4.1\,\text{s}}$$

(*b*) Using a constant-acceleration equation, relate the final speed of the ball to its initial speed, the acceleration, and its displacement:

$$v_{\text{top}}^2 = v_0^2 + 2a\Delta y$$

or, because $v_{\text{top}} = 0$ and $a = -g$,

$$0 = v_0^2 + 2(-g)H \Rightarrow H = \frac{v_0^2}{2g}$$

Substitute numerical values and evaluate *H*:

$$H = \frac{(20\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)} = \boxed{20\,\text{m}}$$

(*c*) Using the same constant-acceleration equation with which we began part (*a*), express the displacement as a function of time:

$$\Delta y = v_0 t + \tfrac{1}{2}at^2$$

Substitute numerical values to obtain:

$$15\,\text{m} = (20\,\text{m/s})t - \left(\frac{9.81\,\text{m/s}^2}{2}\right)t^2$$

Use your graphing calculator or the quadratic formula to solve this equation for the times at which the displacement of the ball is 15 m:

The solutions are $t = \boxed{0.99\,\text{s}}$ (this corresponds to passing 15 m on the way up) and $t = \boxed{3.1\,\text{s}}$ (this corresponds to passing 15 m on the way down).

70 •• In the Blackhawk landslide in California, a mass of rock and mud fell 460 m down a mountain and then traveled 8.00 km across a level plain. It has been theorized that the rock and mud moved on a cushion of water vapor. Assume that the mass dropped with the free-fall acceleration and then slid horizontally, losing speed at a constant rate. (*a*) How long did the mud take to drop the 460 m? (*b*) How fast was it traveling when it reached the bottom? (*c*) How long did the mud take to slide the 8.00 km horizontally?

Picture the Problem This is a multipart constant-acceleration problem using two different constant accelerations. We'll choose a coordinate system in which downward is the positive direction and apply constant-acceleration equations to find the required times.

(*a*) Using a constant-acceleration equation, relate the time for the slide to the distance of fall and the acceleration:

$$\Delta y = y - y_0 = h - 0 = v_0 t_1 + \tfrac{1}{2} a t_1^2$$

or, because $v_0 = 0$,

$$h = \tfrac{1}{2} a t_1^2 \Rightarrow t_1 = \sqrt{\frac{2h}{g}}$$

Substitute numerical values and evaluate t_1:

$$t_1 = \sqrt{\frac{2(460\,\text{m})}{9.81\,\text{m/s}^2}} = 9.684\,\text{s} = \boxed{9.68\,\text{s}}$$

(*b*) Using a constant-acceleration equation, relate the velocity at the bottom of the mountain to the acceleration and time:

$$v_1 = v_0 + a_1 t_1$$

or, because $v_0 = 0$ and $a_1 = g$,

$$v_1 = g t_1$$

Substitute numerical values and evaluate v_1:

$$v_1 = (9.81\,\text{m/s}^2)(9.684\,\text{s}) = \boxed{95.0\,\text{m/s}}$$

(*c*) Using a constant-acceleration equation, relate the time required to stop the mass of rock and mud to its average speed and the distance it slides:

$$\Delta t = \frac{\Delta x}{v_{\text{av}}}$$

Because the acceleration is constant:

$$v_{\text{av}} = \frac{v_1 + v_{\text{f}}}{2} = \frac{v_1 + 0}{2} = \frac{v_1}{2}$$

Substitute for v_{av} to obtain:

$$\Delta t = \frac{2\Delta x}{v_1}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2(8000\,\text{m})}{95.0\,\text{m/s}} = \boxed{168\,\text{s}}$$

71 •• [SSM] A load of bricks is lifted by a crane at a steady velocity of 5.0 m/s when one brick falls off 6.0 m above the ground. (*a*) Sketch the position of the brick $y(t)$ versus time from the moment it leaves the pallet until it hits the ground. (*b*) What is the greatest height the brick reaches above the ground? (*c*) How long does it take to reach the ground? (*d*) What is its speed just before it hits the ground?

Picture the Problem In the absence of air resistance, the brick experiences constant acceleration and we can use constant-acceleration equations to describe its motion. Constant acceleration implies a parabolic position-versus-time curve.

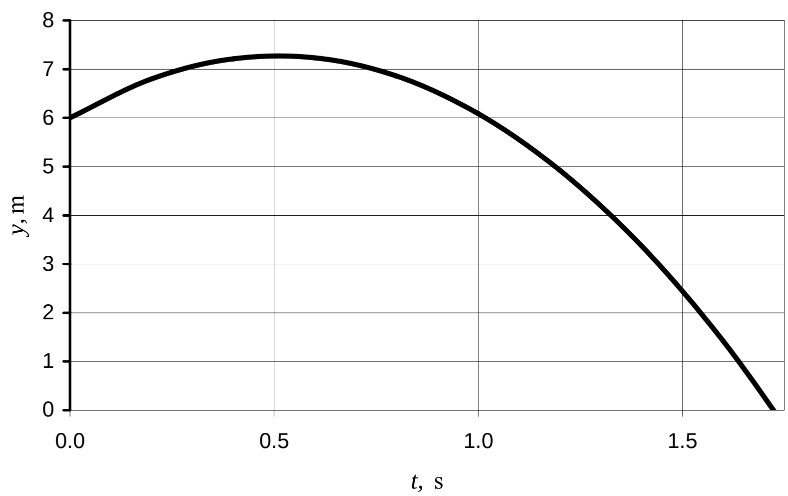
(*a*) Using a constant-acceleration equation, relate the position of the brick to its initial position, initial velocity, acceleration, and time into its fall:

$$y = y_0 + v_0 t + \tfrac{1}{2}(-g)t^2$$

Substitute numerical values to obtain:

$$y = 6.0\,\text{m} + (5.0\,\text{m/s})t - (4.91\,\text{m/s}^2)t^2 \qquad (1)$$

The following graph of $y = 6.0\,\text{m} + (5.0\,\text{m/s})t - (4.91\,\text{m/s}^2)t^2$ was plotted using a spreadsheet program:



(*b*) Relate the greatest height reached by the brick to its height when it falls off the load and the additional height it rises Δy_{max}:

$$h = y_0 + \Delta y_{max} \qquad (2)$$

Using a constant-acceleration equation, relate the height reached by the brick to its acceleration and initial velocity:

$$v_{top}^2 = v_0^2 + 2(-g)\Delta y_{max}$$

or, because $v_{top} = 0$,

$$0 = v_0^2 + 2(-g)\Delta y_{max} \Rightarrow \Delta y_{max} = \frac{v_0^2}{2g}$$

Substitute numerical values and evaluate Δy_{max}:

$$\Delta y_{max} = \frac{(5.0\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)} = 1.3\,\text{m}$$

Substitute numerical values in equation (2) and evaluate *h*:

$$h = 6.0\,\text{m} + 1.3\,\text{m} = \boxed{7.3\,\text{m}}$$

The graph shown above confirms this result.

(*c*) Setting $y = 0$ in equation (1) yields:

$$0 = 6.0\,\text{m} + (5.0\,\text{m/s})t - (4.91\,\text{m/s}^2)t^2$$

Use the quadratic equation or your graphing calculator to obtain:

$t = \boxed{1.7\,\text{s}}$ and $t = -0.71$ s. The negative value for *t* yields (from $v = v_0 - gt$) $v = -12$ m/s and so has no physical meaning.

(*d*) Using a constant-acceleration equation, relate the speed of the brick on impact to its acceleration and displacement:

$$v^2 = v_0^2 + 2gh$$

or, because $v_0 = 0$,

$$v^2 = 2gh \Rightarrow v = \sqrt{2gh}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{2(9.81\,\text{m/s}^2)(7.3\,\text{m})} = \boxed{12\,\text{m/s}}$$

72 •• A bolt comes loose from underneath an elevator that is moving upward at a speed of 6.0 m/s. The bolt reaches the bottom of the elevator shaft in 3.0 s. (*a*) How high above the bottom of the shaft was the elevator when the bolt came loose? (*b*) What is the speed of the bolt when it hits the bottom of the shaft?

Picture the Problem In the absence of air resistance, the acceleration of the bolt is constant. Choose a coordinate system in which upward is positive and the origin is at the bottom of the shaft ($y = 0$).

(*a*) Using a constant-acceleration equation, relate the position of the bolt to its initial position, initial velocity, and fall time:

$$y_{\text{bottom}} = 0 = y_0 + v_0 t + \tfrac{1}{2}(-g)t^2$$

Solve for the position of the bolt when it came loose:

$$y_0 = -v_0 t + \tfrac{1}{2}gt^2$$

Substitute numerical values and evaluate y_0:

$$y_0 = -\left(6.0\,\frac{\text{m}}{\text{s}}\right)(3.0\,\text{s}) + \tfrac{1}{2}\left(9.81\,\frac{\text{m}}{\text{s}^2}\right)(3.0\,\text{s})^2 = \boxed{26\,\text{m}}$$

(*b*) Using a constant-acceleration equation, relate the speed of the bolt to its initial speed, acceleration, and fall time:

$$v = v_0 + at$$

Substitute numerical values and evaluate $|v|$:

$$v = 6.0\,\frac{\text{m}}{\text{s}} - \left(9.81\,\frac{\text{m}}{\text{s}^2}\right)(3.0\text{ s}) = -23\text{ m/s}$$

and

$$|v| = \boxed{23\text{ m/s}}$$

73 •• An object is dropped from rest at a height of 120 m. Find the distance it falls during its final second in the air.

Picture the Problem In the absence of air resistance, the object's acceleration is constant. Choose a coordinate system in which downward is the +*y* direction and the origin is at the point of release. In this coordinate system, $a = g$ and $y = 120$ m at the bottom of the fall.

Express the distance fallen in the last second in terms of the object's position at impact and its position 1 s before impact:

$$\Delta y_{\substack{\text{last}\\\text{second}}} = y - \tfrac{1}{2}gt^2 \qquad (1)$$

where *t* is the time the object has been falling.

Using a constant-acceleration equation, relate the object's position upon impact to its initial position, initial velocity, and fall time:

$$y = y_0 + v_0 t + \tfrac{1}{2}gt^2$$

or, because $y_0 = 0$ and $v_0 = 0$,

$$y = \tfrac{1}{2}gt_{\text{fall}}^2 \Rightarrow t_{\text{fall}} = \sqrt{\frac{2y}{g}}$$

Substitute numerical values and evaluate t_{fall}:

$$t_{\text{fall}} = \sqrt{\frac{2(120\text{ m})}{9.81\text{ m/s}^2}} = 4.95\text{ s}$$

Evaluating equation (1) for $t = 3.95$ s gives:

$$\Delta y_{\substack{\text{last}\\\text{second}}} = 120\text{ m} - \tfrac{1}{2}(9.81\text{ m/s}^2)(3.95\text{ s})^2 = \boxed{44\text{ m}}$$

74 •• An object is released from rest at a height *h*. During the final second of its fall, it traverses a distance of 38 m. Determine *h*.

Picture the Problem In the absence of air resistance, the acceleration of the object is constant. Choose a coordinate system with the origin at the point of release and downward as the positive direction.

Using a constant-acceleration equation, relate the height h of the object to its initial and final velocities and acceleration:

$$v_{\rm f}^2 = v_0^2 + 2a\Delta y$$

or, because $v_0 = 0$, $a = g$, and $\Delta y = h$,

$$v_{\rm f}^2 = 2gh \Rightarrow h = \frac{v_{\rm f}^2}{2g} \qquad (1)$$

Using the definition of average velocity, find the average velocity of the object during its final second of fall:

$$v_{\rm av} = \frac{v_{\rm f\text{-}1s} + v_{\rm f}}{2} = \frac{\Delta y}{\Delta t} = \frac{38\,{\rm m}}{1\,{\rm s}} = 38\,{\rm m/s}$$

Express the sum of the final velocity and the velocity 1 s before impact:

$$v_{\rm f\text{-}1s} + v_{\rm f} = 2(38\,{\rm m/s}) = 76\,{\rm m/s}$$

From the definition of acceleration, we know that the change in velocity of the object, during 1 s of fall, is 9.81 m/s:

$$\Delta v = v_{\rm f} - v_{\rm f\text{-}1s} = 9.81\ {\rm m/s}$$

Add the equations that express the sum and difference of $v_{\rm f\text{-}1s}$ and $v_{\rm f}$ to obtain:

$$v_{\rm f\text{-}1s} + v_{\rm f} + v_{\rm f} - v_{\rm f\text{-}1s} = 76\,{\rm m/s} + 9.81\ {\rm m/s}$$

Solving for $v_{\rm f}$ yields:

$$v_{\rm f} = \frac{76\,{\rm m/s} + 9.81\,{\rm m/s}}{2} = 43\,{\rm m/s}$$

Substitute numerical values in equation (1) and evaluate h:

$$h = \frac{(43\,{\rm m/s})^2}{2(9.81\,{\rm m/s^2})} = \boxed{94\,{\rm m}}$$

75 •• [SSM] A stone is thrown vertically downward from the top of a 200-m cliff. During the last half second of its flight, the stone travels a distance of 45 m. Find the initial speed of the stone.

Picture the Problem In the absence of air resistance, the acceleration of the stone is constant. Choose a coordinate system with the origin at the bottom of the trajectory and the upward direction positive. Let $v_{\rm f\text{-}1/2}$ be the speed one-half second before impact and $v_{\rm f}$ the speed at impact.

Using a constant-acceleration equation, express the final speed of the stone in terms of its initial speed, acceleration, and displacement:

$$v_{\rm f}^2 = v_0^2 + 2a\Delta y \Rightarrow v_0 = \sqrt{v_{\rm f}^2 + 2g\Delta y} \quad (1)$$

Find the average speed in the last half second:

$$v_{\text{av}} = \frac{v_{\text{f-1/2}} + v_{\text{f}}}{2} = \frac{\Delta x_{\text{last half second}}}{\Delta t} = \frac{45\,\text{m}}{0.5\,\text{s}}$$
$$= 90\,\text{m/s}$$

and

$$v_{\text{f-1/2}} + v_{\text{f}} = 2(90\,\text{m/s}) = 180\,\text{m/s}$$

Using a constant-acceleration equation, express the change in speed of the stone in the last half second in terms of the acceleration and the elapsed time and solve for the change in its speed:

$$\Delta v = v_{\text{f}} - v_{\text{f-1/2}} = g\Delta t$$
$$= (9.81\,\text{m/s}^2)(0.5\,\text{s})$$
$$= 4.91\,\text{m/s}$$

Add the equations that express the sum and difference of $v_{\text{f}-½}$ and v_{f} and solve for v_{f}:

$$v_{\text{f}} = \frac{180\,\text{m/s} + 4.91\,\text{m/s}}{2} = 92.5\,\text{m/s}$$

Substitute numerical values in equation (1) and evaluate v_0:

$$v_0 = \sqrt{(92.5\text{ m/s})^2 + 2(9.81\text{ m/s}^2)(-200\text{m})}$$
$$= \boxed{68\,\text{m/s}}$$

Remarks: The stone may be thrown either up or down from the cliff and the results after it passes the cliff on the way down are the same.

76 •• An object is released from rest at a height *h*. It travels 0.4*h* during the first second of its descent. Determine the average velocity of the object during its entire descent.

Picture the Problem In the absence of air resistance, the acceleration of the object is constant. Choose a coordinate system in which downward is the positive direction and the object starts from rest. Apply constant-acceleration equations to find the average velocity of the object during its descent.

Express the average velocity of the falling object in terms of its initial and final velocities:

$$v_{\text{av}} = \frac{v_0 + v_{\text{f}}}{2}$$

Using a constant-acceleration equation, express the displacement of the object during the 1st second in terms of its acceleration and the elapsed time:

$$\Delta y_{\text{1st second}} = \frac{gt^2}{2} = 4.91\,\text{m} = 0.4\,h$$

Solving for the displacement *h* gives: $h = 12.3$ m

Using a constant-acceleration equation, express the final velocity of the object in terms of its initial velocity, acceleration, and displacement:

$$v_f^2 = v_0^2 + 2g\Delta y$$

or, because $v_0 = 0$,

$$v_f = \sqrt{2g\Delta y}$$

Substitute numerical values and evaluate the final velocity of the object:

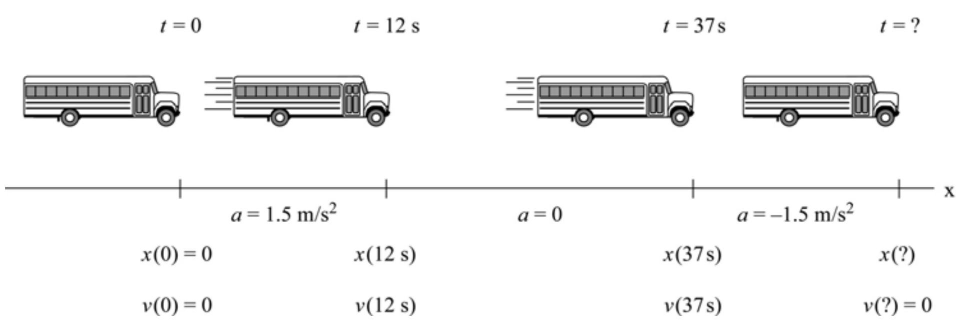
$$v_f = \sqrt{2\left(9.81\,\text{m/s}^2\right)\left(12.3\,\text{m}\right)} = 15.5\,\text{m/s}$$

Substitute in the equation for the average velocity to obtain:

$$v_{av} = \frac{0 + 15.5\,\text{m/s}}{2} = \boxed{7.77\,\text{m/s}}$$

77 •• A bus accelerates from rest at 1.5 m/s^2 for 12 s. It then travels at constant velocity for 25 s, after which it slows to a stop with an acceleration of 1.5 m/s^2. (*a*) What is the total distance that the bus travels? (*b*) What is its average velocity?

Picture the Problem This is a three-part constant-acceleration problem. The bus starts from rest and accelerates for a given period of time, and then it travels at a constant velocity for another period of time, and, finally, decelerates uniformly to a stop. The pictorial representation will help us organize the information in the problem and develop our solution strategy.



(*a*) Express the total displacement of the bus during the three intervals of time:

$$\Delta x_{total} = \Delta x(0 \to 12\,\text{s}) + \Delta x(12\,\text{s} \to 37\,\text{s}) + \Delta x(37\,\text{s} \to \text{end})$$

Using a constant-acceleration equation, express the displacement of the bus during its first 12 s of motion in terms of its initial velocity, acceleration, and the elapsed time; solve for its displacement:

$$\Delta x(0 \to 12\,\text{s}) = v_0 t + \tfrac{1}{2}at^2$$

or, because $v_0 = 0$,

$$\Delta x(0 \to 12\,\text{s}) = \tfrac{1}{2}at^2 = 108\,\text{m}$$

Using a constant-acceleration equation, express the velocity of the bus after 12 seconds in terms of its initial velocity, acceleration, and the elapsed time; solve for its velocity at the end of 12 s:

$$v_{12\,\text{s}} = v_0 + a_{0\to 12\,\text{s}}\Delta t = \left(1.5\,\text{m/s}^2\right)\left(12\,\text{s}\right) = 18\,\text{m/s}$$

During the next 25 s, the bus moves with a constant velocity. Using the definition of average velocity, express the displacement of the bus during this interval in terms of its average (constant) velocity and the elapsed time:

$$\Delta x\left(12\,\text{s} \to 37\,\text{s}\right) = v_{12\,\text{s}}\Delta t = \left(18\,\text{m/s}\right)\left(25\,\text{s}\right) = 450\,\text{m}$$

Because the bus slows down at the same rate that its velocity increased during the first 12 s of motion, we can conclude that its displacement during this braking period is the same as during its acceleration period and the time to brake to a stop is equal to the time that was required for the bus to accelerate to its cruising speed of 18 m/s. Hence:

$$\Delta x\left(37\,\text{s} \to 49\text{s}\right) = 108\,\text{m}$$

Add the displacements to find the distance the bus traveled:

$$\Delta x_{\text{total}} = 108\text{ m} + 450\text{ m} + 108\text{ m} = 666\text{ m} = \boxed{0.67\text{ km}}$$

(*b*) Use the definition of average velocity to calculate the average velocity of the bus during this trip:

$$v_{\text{av}} = \frac{\Delta x_{\text{total}}}{\Delta t} = \frac{666\,\text{m}}{49\,\text{s}} = \boxed{14\,\text{m/s}}$$

Remarks: One can also solve this problem graphically. Recall that the area under a velocity as a function-of-time graph equals the displacement of the moving object.

78 •• Al and Bert are jogging side-by-side on a trail in the woods at a speed of 0.75 m/s. Suddenly Al sees the end of the trail 35 m ahead and decides to speed up to reach it. He accelerates at a constant rate of 0.50 m/s^2, while Bert continues on at a constant speed. (*a*) How long does it take Al to reach the end of the trail? (*b*) Once he reaches the end of the trail, he immediately turns around and heads back along the trail with a constant speed of 0.85 m/s. How long does it take him

to meet up with Bert? (*c*) How far are they from the end of the trail when they meet?

Picture the Problem Because the accelerations of both Al and Bert are constant, constant-acceleration equations can be used to describe their motions. Choose the origin of the coordinate system to be where Al decides to begin his sprint.

(*a*) Using a constant-acceleration equation, relate Al's initial velocity, his acceleration, and the time to reach the end of the trail to his displacement in reaching the end of the trail:

$$\Delta x = v_0 t + \tfrac{1}{2}at^2$$

Substitute numerical values to obtain:

$$35\,\text{m} = (0.75\,\text{m/s})t + \tfrac{1}{2}(0.50\,\text{m/s}^2)t^2$$

Use your graphing calculator or the quadratic formula to solve for the time required for Al to reach the end of the trail:

$$t = 10.43\,\text{s} = \boxed{10\,\text{s}}$$

(*b*) Using constant-acceleration equations, express the positions of Bert and Al as functions of time. At the instant Al turns around at the end of the trail, $t = 0$. Also, $x = 0$ at a point 35 m from the end of the trail:

$$\boldsymbol{x}_{\text{Bert}} = \boldsymbol{x}_{\text{Bert,0}} + (0.75\ \text{m/s})\boldsymbol{t}$$

and

$$x_{\text{Al}} = x_{\text{Al,0}} - (0.85\,\text{m/s})t = 35\,\text{m} - (0.85\,\text{m/s})t$$

Calculate Bert's position at $t = 0$. At that time he has been running for 10.4 s:

$$\boldsymbol{x}_{\text{Bert,0}} = (0.75\,\text{m/s})(10.43\,\text{s}) = 7.823\,\text{m}$$

Because Bert and Al will be at the same location when they meet, equate their position functions and solve for t:

$$7.823\,\text{m} + (0.75\,\text{m/s})t = 35\,\text{m} - (0.85\,\text{m/s})t$$

and

$$t = 16.99\ \text{s}$$

To determine the elapsed time from when Al began his accelerated run, we need to add 10.43 s to this time:

$$t_{\text{start}} = 16.99\,\text{s} + 10.43\,\text{s} = 27.42\,\text{s} = \boxed{27\,\text{s}}$$

(*c*) Express Bert's distance from the end of the trail when he and Al meet:

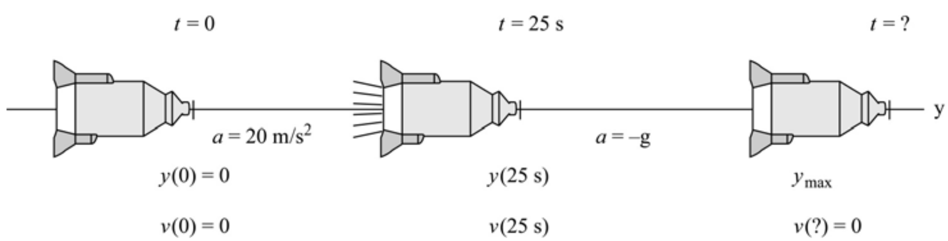
$$d_{\substack{\text{end of}\\ \text{trail}}} = 35\,\text{m} - x_{\text{Bert,0}} - d_{\substack{\text{Bert runs until}\\ \text{he meets Al}}}$$

Substitute numerical values and evaluate $d_{\substack{\text{end of}\\\text{trail}}}$:

$$d_{\substack{\text{end of}\\\text{trail}}} = 35\,\text{m} - 7.823\,\text{m} - (16.99\,\text{s})(0.75\,\text{m/s}) = 14.43\,\text{m} = \boxed{14\,\text{m}}$$

79 •• You have designed a rocket to be used to sample the local atmosphere for pollution. It is fired vertically with a constant upward acceleration of 20 m/s^2. After 25 s, the engine shuts off and the rocket continues rising (in freefall) for a while. (Neglect any effects due to air resistance.) The rocket eventually stops rising and then falls back to the ground. You want to get a sample of air that is 20 km above the ground. (*a*) Did you reach your height goal? If not, what would you change so that the rocket reaches 20 km? (*b*) Determine the total time the rocket is in the air. (*c*) Find the speed of the rocket just before it hits the ground.

Picture the Problem This is a two-part constant-acceleration problem. Choose a coordinate system in which the upward direction is positive and to the right. The pictorial representation will help us organize the information in the problem and develop our solution strategy.



(*a*) Express the highest point the rocket reaches, *h*, as the sum of its displacements during the first two stages of its flight:

$$h = \Delta y_{\text{1st stage}} + \Delta y_{\text{2nd stage}} \qquad (1)$$

Using a constant-acceleration equation, express the altitude reached in the first stage in terms of the rocket's initial velocity, acceleration, and burn time; solve for the first stage altitude:

$$\Delta y_{\text{1st stage}} = v_{0y}t + \tfrac{1}{2}a_{\text{1st stage}}t_{\text{1st stage}}^2$$

or, because $y_{0y} = 0$,

$$\Delta y_{\text{1st stage}} = \tfrac{1}{2}a_{\text{1st stage}}t_{\text{1st stage}}^2$$

Using a constant-acceleration equation, express the speed of the rocket at the end of its first stage in terms of its initial speed, acceleration, and displacement:

$$v_{\text{1st stage}} = v_{0y} + a_{\text{1st stage}}t_{\text{1st stage}}$$

or, because $y_{0y} = 0$,

$$v_{\text{1st stage}} = a_{\text{1st stage}}t_{\text{1st stage}}$$

Using a constant-acceleration equation, express the final speed of the rocket during the remainder of its climb in terms of its shut-off speed, free-fall acceleration, and displacement:

$$v_{\substack{\text{highest}\\\text{point}}}^2 = v_{\text{shutoff}}^2 + 2a_{\text{2nd stage}}\Delta y_{\text{2nd stage}}$$

or, because $v_{\substack{\text{highest}\\\text{point}}} = 0$ and $a_{\text{2nd stage}} = -g$,

$$0 = v_{\text{shutoff}}^2 - 2g\Delta y_{\text{2nd stage}}$$

Solving for $\Delta y_{\text{2nd stage}}$ yields:

$$\Delta y_{\text{2nd stage}} = \frac{v_{\text{shutoff}}^2}{2g}$$

Using a constant-acceleration equation, express the speed of the rocket at the end of its first stage in terms is its initial speed, acceleration, and displacement:

$$v_{\text{1st stage}} = v_0 + a_{\text{1st stage}}t_{\text{1st stage}}$$

or, because $v_0 = 0$ and $v_{\text{1st stage}} = v_{\text{shutoff}}$,

$$v_{\text{shutoff}} = a_{\text{1st stage}}t_{\text{1st stage}}$$

Substituting for v_{shutoff} yields:

$$\Delta y_{\text{2nd stage}} = \frac{(a_{\text{1st stage}}t_{\text{1st stage}})^2}{2g}$$

Substitute for $\Delta y_{\text{1st stage}}$ and $\Delta y_{\text{2nd stage}}$ in equation (1) and simplify to obtain:

$$h = \tfrac{1}{2}a_{\text{1st stage}}t_{\text{1st stage}}^2 + \frac{(a_{\text{1st stage}}t_{\text{1st stage}})^2}{2g}$$

$$= \left(\frac{1}{2} + \frac{a_{\text{1st stage}}}{2g}\right)a_{\text{1st stage}}t_{\text{1st stage}}^2$$

Substitute numerical values and evaluate *h*:

$$h = \left(\frac{1}{2} + \frac{20\,\dfrac{\text{m}}{\text{s}^2}}{2\left(9.81\,\dfrac{\text{m}}{\text{s}^2}\right)}\right)\left(20\,\frac{\text{m}}{\text{s}^2}\right)(25\text{ s})^2$$

$$\approx 19\text{ km}$$

You did not achieve your goal. To go higher, you can increase the acceleration value or the time of acceleration.

(*b*) Express the total time the rocket is in the air in terms of the three segments of its flight:

$$\Delta t_{\text{total}} = \Delta t_{\substack{\text{powered}\\\text{climb}}} + \Delta t_{\substack{\text{2nd}\\\text{segment}}} + \Delta t_{\text{descent}}$$

$$= 25\text{ s} + \Delta t_{\substack{\text{2nd}\\\text{segment}}} + \Delta t_{\text{descent}}$$

Express $\Delta t_{\text{2nd segment}}$ in terms of the rocket's displacement and average speed during the second segment:

$$\Delta t_{\text{2nd segment}} = \frac{\Delta y_{\substack{\text{2nd}\\\text{segment}}}}{v_{\text{av, 2nd segment}}}$$

Substituting for $\Delta y_{\text{2nd segment}}$ and simplifying yields:

$$\Delta t_{\text{2nd segment}} = \frac{\dfrac{\left(a_{\text{1st stage}} t_{\text{1st stage}}\right)^2}{2g}}{v_{\text{av, 2nd segment}}} = \frac{\left(a_{\text{1st stage}} t_{\text{1st stage}}\right)^2}{2g v_{\text{av, 2nd segment}}}$$

Using a constant-acceleration equation, relate the fall distance to the descent time:

$$\Delta y_{\text{descent}} = v_0 t + \tfrac{1}{2} g \left(\Delta t_{\text{descent}}\right)^2$$

or, because $v_0 = 0$,

$$\Delta y_{\text{descent}} = \tfrac{1}{2} g \left(\Delta t_{\text{descent}}\right)^2$$

Solving for $\Delta t_{\text{descent}}$ yields:

$$\Delta t_{\text{descent}} = \sqrt{\frac{2\Delta y_{\text{descent}}}{g}}$$

Substitute for $\Delta t_{\text{2nd segment}}$ and $\Delta t_{\text{descent}}$ in the expression for Δt_{total} to obtain:

$$\Delta t_{\text{total}} = 25\,\text{s} + \frac{\left(a_{\text{1st stage}} \Delta t_{\text{1st stage}}\right)^2}{2g v_{\text{av, 2nd segment}}} + \sqrt{\frac{2\Delta y_{\text{descent}}}{g}}$$

Noting that, because the acceleration is constant, $v_{\text{av, 2nd segment}}$ is the average of the initial and final speeds during the second stage, substitute numerical values and evaluate Δt_{total}:

$$\Delta t_{\text{total}} = 25\,\text{s} + \frac{\left(\left(20\,\dfrac{\text{m}}{\text{s}^2}\right)(25\,\text{s})\right)^2}{2\left(9.81\,\dfrac{\text{m}}{\text{s}^2}\right)\left(\dfrac{0 + 500\,\dfrac{\text{m}}{\text{s}}}{2}\right)} + \sqrt{\frac{2\left(19\times10^3\ \text{m}\right)}{9.81\,\dfrac{\text{m}}{\text{s}^2}}} \approx \boxed{1.4\times10^2\ \text{s}}$$

(*c*) Using a constant-acceleration equation, express the impact velocity of the rocket in terms of its initial downward velocity, acceleration under free-fall, and time of descent; solve for its impact velocity:

$$v_{\text{impact}} = v_0 + g\Delta t_{\text{descent}}$$

and, because $v_0 = 0$,

$$v_{\text{impact}} = g\Delta t_{\text{descent}}$$

Substituting for $\Delta t_{\text{descent}}$ yields:

$$v_{\text{impact}} = g\sqrt{\frac{2\Delta y_{\text{descent}}}{g}} = \sqrt{2g\Delta y_{\text{descent}}}$$

Substitute numerical values and evaluate v_{impact}:

$$v_{\text{impact}} = \sqrt{2\left(9.81\,\text{m/s}^2\right)\left(19\,\text{km}\right)} = \boxed{6.1\times10^2\,\text{m/s}}$$

80 •• A flowerpot falls from a windowsill of an apartment that is on the tenth floor of an apartment building. A person in an apartment below, coincidentally in possession of a high-speed high-precision timing system, notices that it takes 0.20 s for the pot to fall past his window, which is 4.0-m from top to bottom. How far above the top of the window is the windowsill from which the pot fell? (Air resistance is negligible.)

Picture the Problem In the absence of air resistance, the acceleration of the flowerpot is constant. Choose a coordinate system in which downward is positive and the origin is at the point from which the flowerpot fell. Let t = time when the pot is at the top of the window, and $t + \Delta t$ the time when the pot is at the bottom of the window. To find the distance from the ledge to the top of the window, first find the time t_{top} that it takes the pot to fall to the top of the window.

Using a constant-acceleration equation, express the distance y below the ledge from which the pot fell as a function of time:

$$y = y_0 + v_0 t + \tfrac{1}{2}at^2$$

or, because $a = g$ and $v_0 = y_0 = 0$,

$$y = \tfrac{1}{2}gt^2$$

Express the position of the pot as it reaches the top of the window:

$$y_{\text{top}} = \tfrac{1}{2}gt_{\text{top}}^2 \qquad (1)$$

Express the position of the pot as it reaches the bottom of the window:

$$y_{\text{bottom}} = \tfrac{1}{2}g\left(t_{\text{top}} + \Delta t_{\text{window}}\right)^2$$

where $\Delta t_{\text{window}} = t_{\text{top}} - t_{\text{bottom}}$

Subtract y_{bottom} from y_{top} to obtain an expression for the displacement Δy_{window} of the pot as it passes the window:

$$\Delta y_{\text{window}} = \tfrac{1}{2}g\left[\left(t_{\text{top}} + \Delta t_{\text{window}}\right)^2 - t_{\text{top}}^2\right] = \tfrac{1}{2}g\left[2t_{\text{top}}\Delta t_{\text{window}} + \left(\Delta t_{\text{window}}\right)^2\right]$$

Solving for t_{top} yields:

$$t_{\text{top}} = \frac{\dfrac{2\Delta y_{\text{window}}}{g} - \left(\Delta t_{\text{window}}\right)^2}{2\Delta t_{\text{window}}}$$

Substitute for t_{top} in equation (1) to obtain:

$$y_{\text{top}} = \tfrac{1}{2}g\left(\frac{\dfrac{2\Delta y_{\text{window}}}{\text{g}} - \left(\Delta t_{\text{window}}\right)^2}{2\Delta t_{\text{window}}}\right)^2$$

Substitute numerical values and evaluate y_{top}:

$$y_{\text{top}} = \tfrac{1}{2}\left(9.81\ \text{m/s}^2\right)\left(\frac{\dfrac{2(4.0\ \text{m})}{9.81\ \text{m/s}^2} - (0.20\ \text{s})^2}{2(0.20\ \text{s})}\right)^2 = \boxed{18\ \text{m}}$$

81 •• **[SSM]** In a classroom demonstration, a glider moves along an inclined air track with constant acceleration. It is projected from the low end of the track with an initial velocity. After 8.00 s have elapsed, it is 100 cm from the low end and is moving along the track at a velocity of –15 cm/s. Find the initial velocity and the acceleration.

Picture the Problem The acceleration of the glider on the air track is constant. Its average acceleration is equal to the instantaneous (constant) acceleration. Choose a coordinate system in which the initial direction of the glider's motion is the positive direction.

Using the definition of acceleration, express the average acceleration of the glider in terms of the glider's velocity change and the elapsed time:

$$a = a_{\text{av}} = \frac{\Delta v}{\Delta t}$$

Using a constant-acceleration equation, express the average velocity of the glider in terms of the displacement of the glider and the elapsed time:

$$v_{\text{av}} = \frac{\Delta x}{\Delta t} = \frac{v_0 + v}{2} \Rightarrow v_0 = \frac{2\Delta x}{\Delta t} - v$$

Substitute numerical values and evaluate v_0:

$$v_0 = \frac{2(100\ \text{cm})}{8.00\ \text{s}} - (-15\ \text{cm/s}) = \boxed{40\ \text{cm/s}}$$

The average acceleration of the glider is:

$$a = \frac{-15\ \text{cm/s} - (40\ \text{cm/s})}{8.00\ \text{s}} = \boxed{-6.9\ \text{cm/s}^2}$$

82 •• A rock dropped from a cliff covers one-third of its total distance to the ground in the last second of its fall. Air resistance is negligible. How high is the cliff?

Picture the Problem In the absence of air resistance, the acceleration of the rock is constant and its motion can be described using the constant-acceleration equations. Choose a coordinate system in which the downward direction is positive and let the height of the cliff, which equals the displacement of the rock, be represented by *h*.

Using a constant-acceleration equation, express the height *h* of the cliff in terms of the initial velocity of the rock, acceleration, and time of fall:

$$\Delta y = v_0 t + \tfrac{1}{2}at^2$$

or, because $v_0 = 0$, $a = g$, and $\Delta y = h$,

$$h = \tfrac{1}{2}gt^2$$

Using this equation, express the displacement of the rock during the first two-thirds of its fall:

$$\tfrac{2}{3}h = \tfrac{1}{2}gt^2 \qquad (1)$$

Using the same equation, express the displacement of the rock during its complete fall in terms of the time required for it to fall this distance:

$$h = \tfrac{1}{2}g(t + 1\,\text{s})^2 \qquad (2)$$

Substitute equation (2) in equation (1) to obtain:

$$t^2 - (4\text{ s})t - 2\text{ s}^2 = 0$$

Use the quadratic formula or your graphing calculator to solve for the positive root:

$$t = 4.45\,\text{s}$$

Evaluate $\Delta t = t + 1$ s:

$$\Delta t = 4.45\text{ s} + 1\text{ s} = 5.45\text{ s}$$

Substitute numerical values in equation (2) and evaluate *h*:

$$h = \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)(5.45\,\text{s})^2 = \boxed{146\,\text{m}}$$

83 •• [SSM] A typical automobile under hard braking loses speed at a rate of about 7.0 m/s^2; the typical reaction time to engage the brakes is 0.50 s. A local school board sets the speed limit in a school zone such that all cars should be able to stop in 4.0 m. (*a*) What maximum speed does this imply for an automobile in this zone? (*b*) What fraction of the 4.0 m is due to the reaction time?

Picture the Problem Assume that the acceleration of the car is constant. The total distance the car travels while stopping is the sum of the distances it travels during the driver's reaction time and the time it travels while braking. Choose a coordinate system in which the positive direction is the direction of motion of the automobile and apply a constant-acceleration equation to obtain a quadratic equation in the car's initial speed v_0.

(*a*) Using a constant-acceleration equation, relate the speed of the car to its initial speed, acceleration, and displacement during braking:

$$v^2 = v_0^2 + 2a\Delta x_{\text{brk}}$$

or, because the final speed of the car is zero,

$$0 = v_0^2 + 2a\Delta x_{\text{brk}} \Rightarrow \Delta x_{\text{brk}} = -\frac{v_0^2}{2a}$$

Express the total distance traveled by the car as the sum of the distance traveled during the reaction time and the distance traveled while slowing down:

$$\Delta x_{\text{tot}} = \Delta x_{\text{react}} + \Delta x_{\text{brk}} = v_0\Delta t_{\text{react}} - \frac{v_0^2}{2a}$$

Rearrange this quadratic equation to obtain:

$$v_0^2 - 2a\Delta t_{\text{react}}v_0 + 2a\Delta x_{\text{tot}} = 0$$

Substitute numerical values and simplify to obtain:

$$v_0^2 + (7.0\,\text{m/s})v_0 - 56\,\text{m}^2/\text{s}^2 = 0$$

Use your graphing calculator or the quadratic formula to solve the quadratic equation for its positive root:

$$v_0 = 4.76\,\text{m/s}$$

Convert this speed to mi/h:

$$v_0 = (4.76\,\text{m/s})\left(\frac{1\,\text{mi/h}}{0.4470\,\text{m/s}}\right) = \boxed{11\,\text{mi/h}}$$

(*b*) Find the reaction-time distance:

$$\Delta x_{\text{react}} = v_0\Delta t_{\text{react}} = (4.76\,\text{m/s})(0.50\,\text{s}) = 2.38\,\text{m}$$

Express and evaluate the ratio of the reaction distance to the total distance:

$$\frac{\Delta x_{\text{react}}}{\Delta x_{\text{tot}}} = \frac{2.38\,\text{m}}{4.0\,\text{m}} = \boxed{0.60}$$

84 •• Two trains face each other on adjacent tracks. They are initially at rest, and their front ends are 40 m apart. The train on the left accelerates rightward at 1.0 m/s^2. The train on the right accelerates leftward at 1.3 m/s^2. (*a*) How far does the train on the left travel before the front ends of the trains pass? (*b*) If the trains are each 150 m in length, how long after the start are they completely past one another, assuming their accelerations are constant?

Picture the Problem Assume that the accelerations of the trains are constant. Choose a coordinate system in which the direction of the motion of the train on the left is the positive direction. Take $x_0 = 0$ as the position of the train on the left at $t = 0$ and note that the acceleration of the train on the right is negative.

(*a*) Using a constant-acceleration equation, express the position of the front of the train on the left as a function of time:

$$x_L = \tfrac{1}{2}a_L t^2 \quad (1)$$

Using a constant-acceleration equation, express the position of the front of the train on the right as a function of time:

$$x_R = 40\,\text{m} + \tfrac{1}{2}a_R t^2$$

Equate x_L and x_R to obtain:

$$\tfrac{1}{2}a_L t^2 = 40\,\text{m} + \tfrac{1}{2}a_R t^2 \Rightarrow t = \sqrt{\frac{80\,\text{m}}{a_L - a_R}}$$

Substituting for t in equation (1) gives:

$$x_L = \tfrac{1}{2}a_L\left(\frac{80\,\text{m}}{a_L - a_R}\right) = \tfrac{1}{2}\left(\frac{80\,\text{m}}{1 - \dfrac{a_R}{a_L}}\right)$$

The acceleration of the train on the left is 1.0 m/s^2 and the acceleration of the train on the right is −1.3 m/s^2. Substitute numerical values and evaluate x_L:

$$x_L = \tfrac{1}{2}\left(\frac{80\,\text{m}}{1 - \dfrac{-1.3\,\text{m/s}^2}{1.0\,\text{m/s}^2}}\right) = \boxed{17\,\text{m}}$$

(*b*) Let the rear of the left train be at the origin at $t = 0$. Then the initial location of the rear end of the train on the right is at $x = 340$ m (150 m + 40 m + 150 m).

Using a constant-acceleration equation, express the position of the rear of the train on the left as a function of time:

$$x_L = \tfrac{1}{2}a_L t^2$$

Using a constant-acceleration equation, express the position of the rear of the train on the right as a function of time:

$$x_R = 340\,\text{m} + \tfrac{1}{2}a_R t^2$$

The trains will be completely past each other when:

$$x_L = x_R \Rightarrow \tfrac{1}{2}a_L t^2 = 340\,\text{m} + \tfrac{1}{2}a_R\, t^2$$

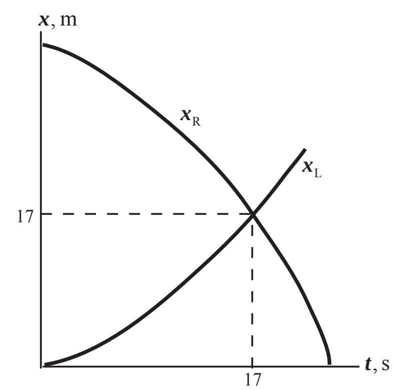
Solving for t yields:

$$t = \sqrt{\frac{680\text{ m}}{a_L - a_R}}$$

Substitute numerical values and evaluate t:

$$t = \sqrt{\frac{680\text{ m}}{1.0\text{ m/s}^2 - \left(-1.3\text{ m/s}^2\right)}} = \boxed{17\text{ s}}$$

Remarks: One can also solve this problem by graphing x_L and x_R as functions of *t*. The coordinates of the intersection of the two curves give one the time-to-passing and the distance traveled by the train on the left for Part (*a*).



85 •• Two stones are dropped from the edge of a 60-m cliff, the second stone 1.6 s after the first. How far below the top of the cliff is the second stone when the separation between the two stones is 36 m?

Picture the Problem In the absence of air resistance, the acceleration of the stones is constant. Choose a coordinate system in which the downward direction is positive and the origin is at the point of release of the stones.

Using constant-acceleration equations, relate the positions of the two stones to their initial positions, accelerations, and time-of-fall:

$$x_1 = \tfrac{1}{2}gt^2$$

and

$$x_2 = \tfrac{1}{2}g(t - 1.6\text{ s})^2$$

Express the difference between x_1 and x_2:

$$x_1 - x_2 = 36\text{ m}$$

Substitute for x_1 and x_2 to obtain:

$$36\text{ m} = \tfrac{1}{2}gt^2 - \tfrac{1}{2}g\left(t - 1.6\text{ s}\right)^2$$

Solve this equation for the time t at which the stones will be separated by 36 m:

$$t = 3.09\text{ s}$$

Substitute this result in the expression for x_2 and solve for x_2:

$$x_2 = \tfrac{1}{2}\left(9.81\text{ m/s}^2\right)\left(3.09\text{ s} - 1.6\text{ s}\right)^2 = \boxed{11\text{ m}}$$

86 •• A motorcycle officer hidden at an intersection observes a car driven by an oblivious driver who ignores a stop sign and continues through the intersection at constant speed. The police officer takes off in pursuit 2.0 s after the car has passed the stop sign. She accelerates at 4.2 m/s^2 until her speed is 110 km/h, and then continues at this speed until she catches the car. At that instant, the car is 1.4 km from the intersection. (*a*) How long did it take for the officer to catch up to the car? (*b*) How fast was the car traveling?

Picture the Problem The acceleration of the police officer's car is positive and constant and the acceleration of the speeder's car is zero. Choose a coordinate system such that the direction of motion of the two vehicles is the positive direction and the origin is at the stop sign.

(*a*) The time traveled by the car is given by:

$$t_{car} = 2.0\text{ s} + t_1 + t_2 \qquad (1)$$

where t_1 is the time during which the motorcycle was accelerating and t_2 is the time during which the motorcycle moved with constant speed.

Convert 110 km/h into m/s:

$$v_1 = 110\,\frac{\text{km}}{\text{h}} \times \frac{10^3\text{ m}}{\text{km}} \times \frac{1\text{ h}}{3600\text{ s}} = 30.56\,\frac{\text{m}}{\text{s}}$$

Express and evaluate t_1:

$$t_1 = \frac{v_1}{a_{motorcycle}} = \frac{30.56\text{ m/s}}{4.2\text{ m/s}^2} = 7.276\text{ s}$$

Express and evaluate d_1:

$$d_1 = \tfrac{1}{2}v_1 t_1 = \tfrac{1}{2}(30.56\text{ m/s})(7.276\text{ s}) = 111.2\text{ m}$$

Determine d_2:

$$d_2 = d_{caught} - d_1 = 1400\text{ m} - 111\text{ m} = 1289\text{ m}$$

Express and evaluate t_2:

$$t_2 = \frac{d_2}{v_1} = \frac{1289\text{ m}}{30.56\text{ m/s}} = 42.18\text{ s}$$

Substitute in equation (1) and evaluate t_{car}:

$$t_{car} = 2.0\text{ s} + 7.3\text{ s} + 42.2\text{ s} = 51.5\text{ s} = \boxed{52\text{ s}}$$

(*b*) The speed of the car when it was overtaken is the ratio of the distance it traveled to the elapsed time:

$$v_{car} = \frac{d_{caught}}{t_{car}}$$

Substitute numerical values and evaluate v_{car}:

$$v_{car} = \left(\frac{1400\text{ m}}{51.5\text{ s}}\right)\left(\frac{1\text{ mi/h}}{0.447\text{ m/s}}\right) = \boxed{61\text{ mi/h}}$$

87 •• At $t = 0$, a stone is dropped from the top of a cliff above a lake. Another stone is thrown downward 1.6 s later from the same point with an initial speed of 32 m/s. Both stones hit the water at the same instant. Find the height of the cliff.

Picture the Problem In the absence of air resistance, the acceleration of the stone is constant. Choose a coordinate system in which downward is positive and the origin is at the point of release of the stone and apply constant-acceleration equations.

Using a constant-acceleration equation, express the height of the cliff in terms of the initial position of the stones, acceleration due to gravity, and time for the first stone to hit the water:

$$h = \tfrac{1}{2}gt_1^2$$

Express the displacement of the second stone when it hits the water in terms of its initial velocity, acceleration, and time required for it to hit the water.

$$d_2 = v_{02}t_2 + \tfrac{1}{2}gt_2^2$$

where $t_2 = t_1 - 1.6$ s.

Because the stones will travel the same distances before hitting the water, equate h and d_2 to obtain:

$$\tfrac{1}{2}gt_1^2 = v_{02}t_2 + \tfrac{1}{2}gt_2^2$$

or, because $t_2 = t_1 - 1.6$ s,

$$\tfrac{1}{2}gt_1^2 = v_{02}t_2 + \tfrac{1}{2}g(t_1 - 1.6\text{ s})^2$$

Substitute numerical values to obtain:

$$\tfrac{1}{2}(9.81\text{ m/s}^2)t_1^2 = (32\text{ m/s})(t_1 - 1.6\text{ s}) + \tfrac{1}{2}(9.81\text{ m/s}^2)(t_1 - 1.6\text{ s})^2$$

Solving this quadratic equation for t_1 yields:

$$t_1 = 2.370\text{ s}$$

Substitute for t_1 and evaluate h:

$$h = \tfrac{1}{2}(9.81\text{ m/s}^2)(2.370\text{ s})^2 = \boxed{28\text{ m}}$$

88 •• A passenger train is traveling at 29 m/s when the engineer sees a freight train 360 m ahead of his train traveling in the same direction on the same track. The freight train is moving at a speed of 6.0 m/s. (*a*) If the reaction time of the engineer is 0.40 s, what is the minimum (constant) rate at which the passenger train must lose speed if a collision is to be avoided? (*b*) If the engineer's reaction

time is 0.80 s and the train loses speed at the minimum rate described in Part (*a*), at what rate is the passenger train approaching the freight train when the two collide? (*c*) How far will the passenger train have traveled in the time between the sighting of the freight train and the collision?

Picture the Problem Assume that the acceleration of the passenger train is constant. Let $x_p = 0$ be the location of the passenger train engine at the moment of sighting the freight train's end; let $t = 0$ be the instant the passenger train begins to slow (0.40 s after the passenger train engineer sees the freight train ahead). Choose a coordinate system in which the direction of motion of the trains is the positive direction and use constant-acceleration equations to express the positions of the trains in terms of their initial positions, speeds, accelerations, and elapsed time.

(*a*) Using constant-acceleration equations, write expressions for the positions of the front of the passenger train and the rear of the freight train, x_p and x_f, respectively:

$$x_p = (29\,\text{m/s})(t + 0.40\,\text{s}) - \tfrac{1}{2}at^2 \quad (1)$$

and

$$\boldsymbol{x}_f = (360\,\text{m}) + (6.0\,\text{m/s})(\boldsymbol{t} + 0.40\,\text{s})$$

where x_p and x_f are in meters if t is in seconds.

Equate x_f and x_p to obtain an equation for t:

$$\tfrac{1}{2}at^2 - (23\,\text{m/s})t + 350.8\,\text{m} = 0$$

Find the discriminant $(D = \text{B}^2 - 4\text{AC})$ of this equation:

$$D = (23\,\text{m/s})^2 - 4\left(\frac{a}{2}\right)(350.8\,\text{m})$$

The equation must have real roots if it is to describe a collision. The necessary condition for real roots is that the discriminant be greater than or equal to zero:

If $(23\text{ m/s})^2 - a\,(701.6\text{ m}) \geq 0$, then $a \leq \boxed{0.75\text{ m/s}^2}$

(*b*) Differentiate equation (1) to express the speed of the passenger train as a function of time:

$$v_p(t) = \frac{dx_p(t)}{dt} = 29\,\text{m/s} - at \qquad (2)$$

Repeat the previous steps with $a = 0.75\text{ m/s}^2$ and a 0.80 s reaction time. The quadratic equation that guarantees real roots with the longer reaction time is:

$$(0.375\,\text{m/s}^2)t^2 - (23\,\text{m/s})t + 341.6\text{m} = 0$$

Use the quadratic formula or your graphing calculator to find the collision times:

$t = 25.23$ s and $t = 36.10$ s

Because, when $t = 36.10$ s, the trains have already collided, this root is not a meaningful solution to our problem.

Note: In the graph shown below, you will see why we keep only the smaller of the two solutions.

Evaluate equation (2) for $t = 25.23$ s and $a = 0.75$ m/s^2:

$$v_p(t) = 29\ \text{m/s} - \left(0.75\ \text{m/s}^2\right)(25.23\ \text{s})$$
$$= \boxed{10\ \text{m/s}}$$

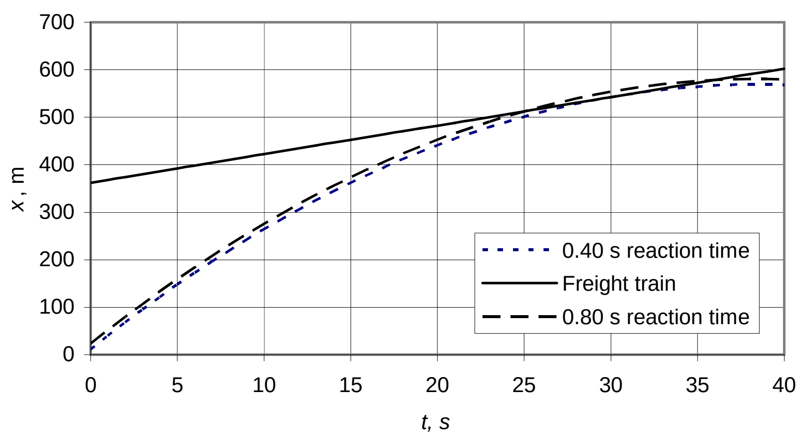
(*c*) The position of the passenger train as a function of time is given by:

$$x_p(t) = (29\ \text{m/s})(t + 0.80\ \text{s}) - \tfrac{1}{2}\left(0.75\ \text{m/s}^2\right)t^2$$

Evaluate $\boldsymbol{x}_p(25.23\ \text{s})$ to obtain:

$$\boldsymbol{x}_p(26\ \text{s}) = (29\ \text{m/s})(25.23\ \text{s} + 0.80\ \text{s}) - \tfrac{1}{2}\left(0.75\ \text{m/s}^2\right)(25.23\ \text{s})^2 = \boxed{0.52\ \text{km}}$$

The following graph shows the positions of the trains as a function of time. The solid straight line is for the constant velocity freight train; the dashed curves are for the passenger train, with reaction times of 0.40 s for the lower curve and 0.80 s for the upper curve.



Remarks: A collision occurs the first time the curve for the passenger train crosses the curve for the freight train. The smaller of the two solutions will always give the time of the collision.

89 •• The click beetle can project itself vertically with an acceleration of about 400*g* (an order of magnitude more than a human could survive!). The beetle jumps by "unfolding" its 0.60-cm long legs. (*a*) How high can the click beetle jump? (*b*) How long is the beetle in the air? (Assume constant acceleration while in contact with the ground and neglect air resistance.)

Picture the Problem Choose a coordinate system in which the upward direction is positive. We can use a constant-acceleration equation to find the beetle's speed as its feet lose contact with the ground and then use this speed to calculate the height of its jump.

(*a*) Using a constant-acceleration equation, relate the beetle's maximum height to its launch speed, speed at the top of its trajectory, and acceleration once it is airborne; solve for its maximum height:

$$v_{\substack{\text{highest}\\\text{point}}}^2 = v_{\text{launch}}^2 + 2a\Delta y_{\text{free fall}} = v_{\text{launch}}^2 + 2(-g)h$$

or, because $v_{\substack{\text{highest}\\\text{point}}} = 0$,

$$0 = v_{\text{launch}}^2 + 2(-g)h \Rightarrow h = \frac{v_{\text{launch}}^2}{2g} \quad (1)$$

Now, in order to determine the beetle's launch speedy, relate its time of contact with the ground to its acceleration and push-off distance:

$$v_{\text{launch}}^2 = v_0^2 + 2a\Delta y_{\text{launch}}$$

or, because $v_0 = 0$,

$$v_{\text{launch}}^2 = 2a\Delta y_{\text{launch}}$$

Substituting for v_{launch}^2 in equation (1) yields:

$$h = \frac{2a\Delta y_{\text{launch}}}{2g}$$

Substitute numerical values in equation (1) to find the height to which the beetle can jump:

$$h = \frac{2(400)(9.81\,\text{m/s}^2)(0.60\times10^{-2}\,\text{m})}{2(9.81\,\text{m/s}^2)} = \boxed{2.4\,\text{m}}$$

(*b*) Using a constant-acceleration equation, relate the speed of the beetle at its maximum height to its launch speed, free-fall acceleration while in the air, and time-to-maximum height:

$$v = v_0 + at$$

or

$$v_{\substack{\text{max.}\\\text{height}}} = v_{\text{launch}} - gt_{\substack{\text{max}\\\text{height}}}$$

and, because $v_{\substack{\text{max}\\\text{height}}} = 0$,

$$0 = v_{\text{launch}} - gt_{\substack{\text{max}\\\text{height}}} \Rightarrow t_{\substack{\text{max}\\\text{height}}} = \frac{v_{\text{launch}}}{g}$$

For zero displacement and constant acceleration, the time-of-flight is twice the time-to-maximum height:

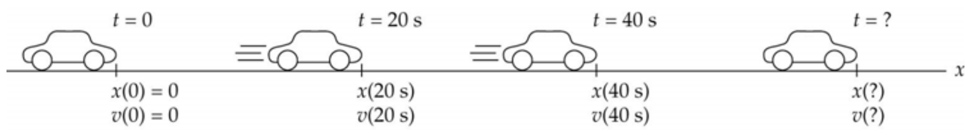
$$t_{\text{flight}} = 2t_{\substack{\text{max}\\\text{height}}} = \frac{2v_{\text{launch}}}{g}$$

Substitute numerical values and evaluate t_{flight}:

$$t_{\text{flight}} = \frac{2(6.9\,\text{m/s})}{9.81\,\text{m/s}^2} = \boxed{1.4\,\text{s}}$$

90 •• An automobile accelerates from rest at 2.0 m/s^2 for 20 s. The speed is then held constant for 20 s, after which there is an acceleration of –3.0 m/s^2 until the automobile stops. What is the total distance traveled?

Picture the Problem This is a multipart constant-acceleration problem using three different constant accelerations (+2.0 m/s^2 for 20 s, then zero for 20 s, and then –3.0 m/s^2 until the automobile stops). The final speed is zero. The pictorial representation will help us organize the information in the problem and develop a solution strategy.



Add up all the displacements to get the total:

$$\Delta x_{03} = \Delta x_{01} + \Delta x_{12} + \Delta x_{23} \qquad (1)$$

Using constant-acceleration formulas, find the first displacement:

$$\Delta x_{01} = v_0 t_1 + \tfrac{1}{2} a_{01} t_1^2$$

or, because $v_0 = 0$,

$$\Delta x_{01} = \tfrac{1}{2} a_{01} t_1^2$$

The speed is constant for the second displacement. The second displacement is given by:

$$\Delta x_{12} = v_1 (t_2 - t_1)$$

or, because $v_1 = v_0 + a_{01} t_1 = 0 + a_{01} t_1$,

$$\Delta x_{12} = a_{01} t_1 (t_2 - t_1)$$

The displacement during the braking interval is related to v_3, v_2, and a_{23}:

$$v_3^2 = v_2^2 + 2a_{23} \Delta x_{23}$$

and, because $v_2 = v_1 = a_{01} t_1$ and $v_3 = 0$,

$$\Delta x_{23} = \frac{-(a_{01} t_1)^2}{2a_{23}}$$

Substituting for $\Delta x_{01}, \Delta x_{12}$, and Δx_{23} in equation (1) yields:

$$\Delta x_{03} = \tfrac{1}{2} a_{01} t_1^2 + a_{01} t_1 (t_2 - t_1) - \frac{(a_{01} t_1)^2}{2a_{23}}$$

Substitute numerical values and evaluate Δx_{03}:

$$\Delta x_{03} = \tfrac{1}{2}(2.0\ \text{m/s})(20\ \text{s})^2 + (2.0\ \text{m/s})(20\ \text{s})(40\ \text{s} - 20\ \text{s}) - \frac{[(2.0\ \text{m/s})(20\ \text{s})]^2}{2(-3.0\ \text{m/s}^2)}$$

$$= \boxed{1.5\ \text{km}}$$

Remarks: Because the area under the curve of a velocity-versus-time graph equals the displacement of the object experiencing the acceleration, we could

solve this problem by plotting the velocity as a function of time and finding the area bounded by it and the time axis.

91 •• [SSM] Consider measuring the free-fall motion of a particle (neglect air resistance). Before the advent of computer-driven data-logging software, these experiments typically employed a wax-coated tape placed vertically next to the path of a dropped electrically conductive object. A spark generator would cause an arc to jump between two vertical wires through the falling object and through the tape, thereby marking the tape at fixed time intervals Δt. Show that the change in height during successive time intervals for an object falling from rest follows *Galileo's Rule of Odd Numbers*: $\Delta y_{21} = 3\Delta y_{10}$, $\Delta y_{32} = 5\Delta y_{10}$, . . . , where Δy_{10} is the change in y during the first interval of duration Δt, Δy_{21} is the change in y during the second interval of duration Δt, etc.

Picture the Problem In the absence of air resistance, the particle experiences constant acceleration and we can use constant-acceleration equations to describe its position as a function of time. Choose a coordinate system in which downward is positive, the particle starts from rest ($v_o = 0$), and the starting height is zero ($y_0 = 0$).

Using a constant-acceleration equation, relate the position of the falling particle to the acceleration and the time. Evaluate the y-position at successive equal time intervals Δt, $2\Delta t$, $3\Delta t$, etc:

$$y_1 = -\frac{1}{2}g(\Delta t)^2$$

$$y_2 = -\frac{1}{2}g(2\Delta t)^2 = -\frac{4}{2}g(\Delta t)^2$$

$$y_3 = -\frac{1}{2}(3\Delta t)^2 = -\frac{9}{2}g(\Delta t)^2$$

$$y_4 = -\frac{1}{2}g(4\Delta t)^2 = -\frac{16}{2}g(\Delta t)^2$$

etc.

Evaluate the changes in those positions in each time interval:

$$\Delta y_{10} = y_1 - 0 = \left(-\frac{1}{2}g\right)(\Delta t)^2$$

$$\begin{aligned}\Delta y_{21} = y_2 - y_1 &= -\frac{4}{2}g(\Delta t)^2 + \frac{1}{2}g(\Delta t)^2 \\ &= -\frac{3}{2}g(\Delta t)^2 = 3\left[-\frac{1}{2}g(\Delta t)^2\right] \\ &= 3\Delta y_{10}\end{aligned}$$

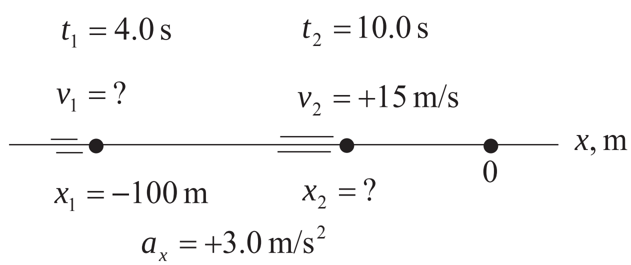
$$\Delta y_{32} = y_3 - y_2 = -\frac{9}{2}g(\Delta t)^2 + \frac{4}{2}g(\Delta t)^2$$
$$= -\frac{5}{2}g(\Delta t)^2 = 5\left[-\frac{1}{2}g(\Delta t)^2\right]$$
$$= 5\Delta y_{10}$$

$$\Delta y_{43} = y_4 - y_3 = -\frac{16}{2}g(\Delta t)^2 + \frac{9}{2}g(\Delta t)^2$$
$$= -\frac{7}{2}g(\Delta t)^2 = 7\left[-\frac{1}{2}g(\Delta t)^2\right]$$
$$= 7\Delta y_{10}$$

etc.

92 •• A particle travels along the x axis with a constant acceleration of +3.0 m/s^2. It is at $x = -100$ m at time $t = 4.0$ s. In addition, it has a velocity of +15 m/s at a time 6.0 s later. Find its position at this later time.

Picture the Problem Because the particle moves with a constant acceleration we can use constant-acceleration equations to relate its positions and velocities to the time into its motion. A pictorial representation will help us organize the information in the problem and develop our solution strategy.



Using a constant-acceleration equation, relate the velocity of the particle at time t_2 to its velocity at time t_1:

$$v_2 - v_1 = a_x(t_2 - t_1)$$

Using a constant-acceleration equation, relate the position of the particle at time t_2 to its position at time t_1:

$$x_2 - x_1 = v_1(t_2 - t_1) + \tfrac{1}{2}a_x(t_2 - t_1)^2$$

Eliminating v_1 and solving for x_2 gives:

$$x_2 = x_1 + v_2(t_2 - t_1) - \tfrac{1}{2}a_x(t_2 - t_1)^2$$

Substitute numerical values and evaluate x_2:

$$x_2 = -100\,\text{m} + (+15\,\text{m/s})(10.0\,\text{s} - 4.0\,\text{s}) - \tfrac{1}{2}(+3.0\,\text{m/s}^2)(10.0\,\text{s} - 4.0\,\text{s})^2 = \boxed{-64\,\text{m}}$$

93 •• [SSM] If it were possible for a spacecraft to maintain a constant acceleration indefinitely, trips to the planets of the Solar System could be undertaken in days or weeks, while voyages to the nearer stars would only take a few years. (*a*) Using data from the tables at the back of the book, find the time it would take for a one-way trip from Earth to Mars (at Mars' closest approach to Earth). Assume that the spacecraft starts from rest, travels along a straight line, accelerates halfway at 1*g*, flips around, and decelerates at 1*g* for the rest of the trip. (*b*) Repeat the calculation for a 4.1×10^{13}-km trip to Proxima Centauri, our nearest stellar neighbor outside of the sun. (See Problem 47.)

Picture the Problem Note: No material body can travel at speeds faster than light. When one is dealing with problems of this sort, the kinematic formulae for displacement, velocity and acceleration are no longer valid, and one must invoke the special theory of relativity to answer questions such as these. For now, ignore such subtleties. Although the formulas you are using (i.e., the constant-acceleration equations) are not quite correct, your answer to Part (*b*) will be wrong by about 1%.

(*a*) Let $t_{1/2}$ represent the time it takes to reach the halfway point. Then the total trip time is:

$$t = 2\,t_{1/2} \qquad (1)$$

Use a constant- acceleration equation to relate the half-distance to Mars Δx to the initial speed, acceleration, and half-trip time $t_{1/2}$:

$$\Delta x = v_0 t + \tfrac{1}{2} a t_{1/2}^2$$

Because $v_0 = 0$ and $a = g$:

$$t_{1/2} = \sqrt{\frac{2\Delta x}{a}}$$

Substitute for $t_{1/2}$ in equation (1) to obtain:

$$t = 2\sqrt{\frac{2\Delta x}{a}} \qquad (2)$$

The distance from Earth to Mars at closest approach is 7.8×10^{10} m. Substitute numerical values and evaluate t :

$$t_{\text{round trip}} = 2\sqrt{\frac{2(3.9\times10^{10}\ \text{m})}{9.81\,\text{m/s}^2}} = 18\times10^4\ \text{s}$$

$$\approx \boxed{2.1\,\text{d}}$$

(*b*) From Problem 47 we have:

$$d_{\substack{\text{Proxima}\\ \text{Centauri}}} = 4.1\times10^{13}\ \text{km}$$

Substitute numerical values in equation (2) to obtain:

$$t_{\text{round trip}} = 2\sqrt{\frac{2\left(4.1\times10^{13}\text{ km}\right)}{9.81\,\text{m/s}^2}} = 18\times10^{7}\text{ s}$$

$$\approx \boxed{5.8\text{ y}}$$

Remarks: Our result in Part (*a*) seems remarkably short, considering how far Mars is and how low the acceleration is.

94 • The Stratosphere Tower in Las Vegas is 1137 ft high. It takes 1 min, 20 s to ascend from the ground floor to the top of the tower using the high-speed elevator. The elevator starts and ends at rest. Assume that it maintains a constant upward acceleration until it reaches its maximum speed, and then maintains a constant acceleration of equal magnitude until it comes to a stop. Find the magnitude of the acceleration of the elevator. Express this acceleration magnitude as a multiple of g (the acceleration due to gravity).

Picture the Problem Because the elevator accelerates uniformly for half the distance and uniformly decelerates for the second half, we can use constant-acceleration equations to describe its motion

Let $t_{1/2}$ = 40 s be the time it takes to reach the halfway mark. Use the constant-acceleration equation that relates the acceleration to the known variables to obtain:

$$\Delta y = v_0 t + \tfrac{1}{2}at^2$$

or, because $v_0 = 0$,

$$\Delta y = \tfrac{1}{2}at^2 \Rightarrow a = \frac{2\,\Delta y}{t_{1/2}^2}$$

Substitute numerical values and evaluate a:

$$a = \frac{2\left(\frac{1}{2}\right)\left(1137\,\text{ft}\right)\left(1\,\text{m}/3.281\,\text{ft}\right)}{\left(40\,\text{s}\right)^2} = 0.22\,\text{m/s}^2$$

$$= \boxed{0.022g}$$

95 •• A train pulls away from a station with a constant acceleration of 0.40 m/s^2. A passenger arrives at a point next to the track 6.0 s after the end of the train has passed the very same point. What is the slowest constant speed at which she can run and still catch the train? On a single graph plot the position versus time curves for both the train and the passenger.

Picture the Problem Because the acceleration is constant, we can describe the motions of the train using constant-acceleration equations. Find expressions for the distances traveled, separately, by the train and the passenger. When are they equal? Note that the train is accelerating and the passenger runs at a constant minimum speed (zero acceleration) such that she can just catch the train.

1. Using the subscripts "train" and "p" to refer to the train and the passenger and the subscript "c" to identify "critical" conditions, express the position of the train and the passenger:

$$x_{\text{train c}}(t_c) = \frac{a_{\text{train}}}{2}t_c^2$$

and

$$x_{\text{p,c}}(t_c) = v_{\text{p,c}}(t_c - \Delta t)$$

Express the critical conditions that must be satisfied if the passenger is to catch the train:

$$v_{\text{train c}} = v_{\text{p,c}}$$

and

$$x_{\text{train c}} = x_{\text{p,c}}$$

2. Express the train's average speed:

$$v_{\text{av}}(0 \text{ to } t_c) = \frac{0 + v_{\text{train c}}}{2} = \frac{v_{\text{train c}}}{2}$$

3. Using the definition of average speed, express v_{av} in terms of $x_{\text{p,c}}$ and t_c.

$$v_{\text{av}} = \frac{\Delta x}{\Delta t} = \frac{0 + x_{\text{p,c}}}{0 + t_c} = \frac{x_{\text{p,c}}}{t_c}$$

4. Combine steps 2 and 3 and solve for $x_{\text{p,c}}$.

$$x_{\text{p,c}} = \frac{v_{\text{train c}}t_c}{2}$$

5. Combine steps 1 and 4 and solve for t_c.

$$v_{\text{p,c}}(t_c - \Delta t) = \frac{v_{\text{train c}}t_c}{2}$$

or

$$t_c - \Delta t = \frac{t_c}{2}$$

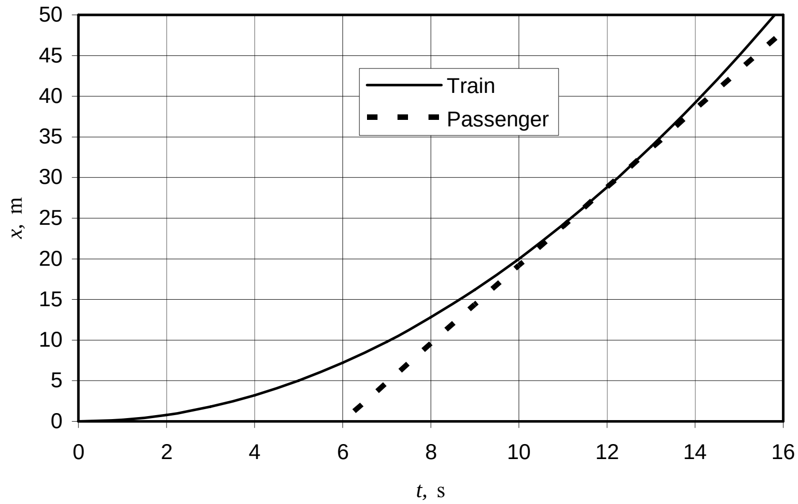
and

$t_c = 2\ \Delta t = 2\ (6\text{ s}) = 12\text{ s}$

6. Finally, combine steps 1 and 5 and solve for $v_{\text{train c}}$.

$$v_{\text{p,c}} = v_{\text{train c}} = a_{\text{train}}t_c = (0.40\,\text{m/s}^2)(12\,\text{s})$$
$$= \boxed{4.8\,\text{m/s}}$$

The following graph shows the location of both the passenger and the train as a function of time. The parabolic solid curve is the graph of $x_{\text{train}}(t)$ for the accelerating train. The straight dashed line is passenger's position $x_p(t)$ if she arrives at $\Delta t = 6.0$ s after the train departs. When the passenger catches the train, our graph shows that her speed and that of the train must be equal ($v_{\text{train c}} = v_{\text{p,c}}$). Do you see why?



96 ••• Ball A is dropped from the top of a building of height h at the same instant that ball B is thrown vertically upward from the ground. When the balls collide, they are moving in opposite directions, and the speed of A is twice the speed of B. At what fraction of the height of the building does the collision occur?

Picture the Problem Both balls experience constant acceleration once they are in flight. Choose a coordinate system with the origin at the ground and the upward direction positive. When the balls collide they are at the same height above the ground.

Using constant-acceleration equations, express the positions of both balls as functions of time. At the ground $y = 0$.

$$y_A = h - \tfrac{1}{2}gt^2$$
and
$$y_B = v_0 t - \tfrac{1}{2}gt^2$$

The conditions at collision are that the heights are equal and the speeds are related:

$$y_A = y_B$$
and
$$v_A = -2v_B$$

Express the speeds of both balls as functions of time:

$$v_A = -gt \quad \text{and} \quad v_B = v_0 - gt$$

Substituting the position and speed functions into the conditions at collision gives:

$$h - \tfrac{1}{2}gt_c^2 = v_0 t_c - \tfrac{1}{2}gt_c^2$$
and
$$-gt_c = -2(v_0 - gt_c)$$
where t_c is the time of collision.

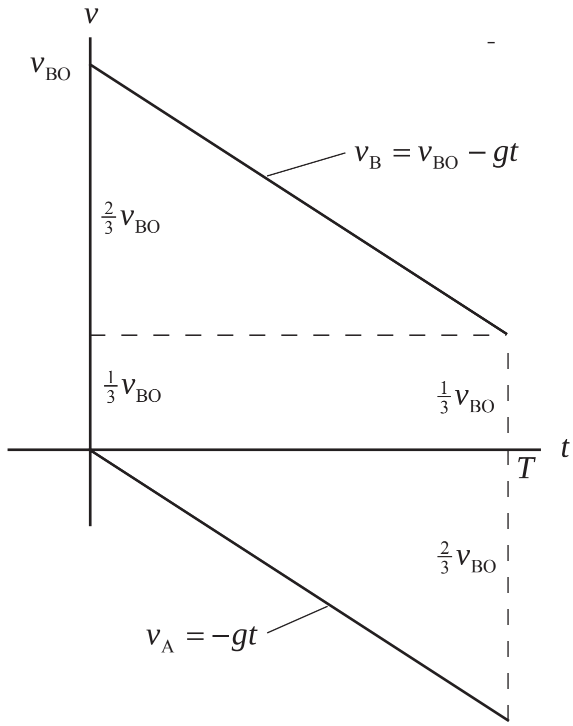
We now have two equations and two unknowns, t_c and v_0. Solving the equations for the unknowns gives:

$$t_c = \sqrt{\frac{2h}{3g}} \quad \text{and} \quad v_0 = \sqrt{\frac{3gh}{2}}$$

Substitute the expression for t_c into the equation for y_A to obtain the height at collision:

$$y_A = h - \tfrac{1}{2}g\left(\frac{2h}{3g}\right) = \boxed{\frac{2h}{3}}$$

Remarks: We can also solve this problem graphically by plotting velocity-versus-time for both balls. Because ball A starts from rest its velocity is given by $v_A = -gt$. Ball B initially moves with an unknown velocity v_{B0} and its velocity is given by $v_B = v_{B0} - gt$. The graphs of these equations are shown below with T representing the time at which they collide.



The height of the building is the sum of the sum of the distances traveled by the balls. Each of these distances is equal to the magnitude of the area "under" the corresponding v-versus-t curve. Thus, the height of the building equals the area of the parallelogram, which is $v_{B0}T$. The distance that A falls is the area of the lower triangle, which is $\tfrac{1}{3}v_{BO}T$. Therefore, the ratio of the distance fallen by A to the height of the building is 1/3, so the collision takes place at 2/3 the height of the building.

97 ••• Solve Problem 96 if the collision occurs when the balls are moving in the same direction and the speed of A is 4 times that of B.

Picture the Problem Both balls are moving with constant acceleration. Take the origin of the coordinate system to be at the ground and the upward direction to be positive. When the balls collide they are at the same height above the ground. The speeds at collision are related by $v_A = 4v_B$.

Using constant-acceleration equations, express the positions of both balls as functions of time:

$$y_A = h - \tfrac{1}{2}gt^2 \text{ and } y_B = v_0 t - \tfrac{1}{2}gt^2$$

The conditions at collision are that the heights are equal and the speeds are related:

$$y_A = y_B \text{ and } v_A = 4v_B$$

Express the speeds of both balls as functions of time:

$$v_A = -gt \text{ and } v_B = v_0 - gt$$

Substitute the position and speed functions into the conditions at collision to obtain:

$$h - \tfrac{1}{2}gt_c^2 = v_0 t_c - \tfrac{1}{2}gt_c^2$$

and

$$-gt_c = 4(v_0 - gt_c)$$

where t_c is the time of collision.

We now have two equations and two unknowns, t_c and v_0. Solving the equations for the unknowns gives:

$$t_c = \sqrt{\frac{4h}{3g}} \text{ and } v_0 = \sqrt{\frac{3gh}{4}}$$

Substitute the expression for t_c into the equation for y_A to obtain the height at collision:

$$y_A = h - \tfrac{1}{2}g\left(\frac{4h}{3g}\right) = \boxed{\frac{h}{3}}$$

98 ••• Starting at one station, a subway train accelerates from rest at a constant rate of 1.00 m/s^2 for half the distance to the next station, then slows down at the same rate for the second half of the journey. The total distance between stations is 900 m. (*a*) Sketch a graph of the velocity v_x as a function of time over the full journey. (*b*) Sketch a graph of the position as a function of time over the full journey. Place appropriate numerical values on both axes.

Picture the Problem The problem describes two intervals of constant acceleration; one when the train's speed is increasing, and a second when it is decreasing.

(*a*) Using a constant-acceleration equation, relate the half-distance Δx between stations to the initial speed v_0, the acceleration a of the train, and the time-to-midpoint Δt:

$$\Delta x = v_0 \Delta t + \tfrac{1}{2}a(\Delta t)^2$$

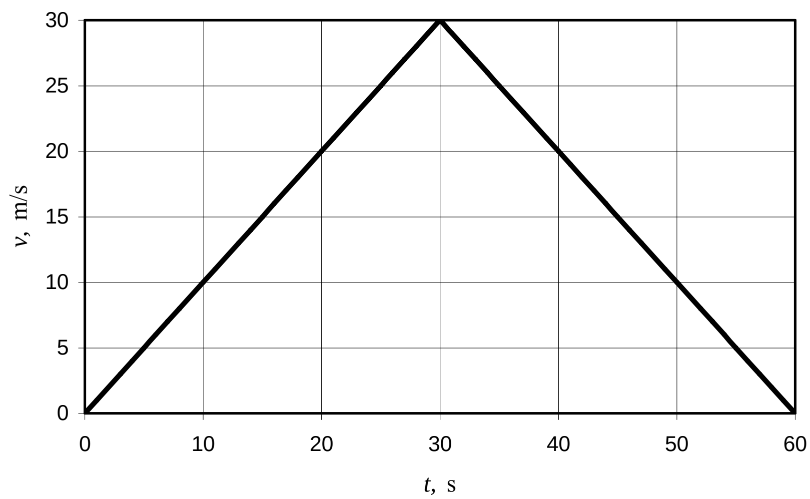
or, because $v_0 = 0$,

$$\Delta x = \tfrac{1}{2}a(\Delta t)^2 \Rightarrow \Delta t = \sqrt{\frac{2\Delta x}{a}}$$

Substitute numerical values and evaluate the time-to-midpoint Δt:

$$\Delta t = \sqrt{\frac{2(450\,\text{m})}{1.00\,\text{m/s}^2}} = 30.0\,\text{s}$$

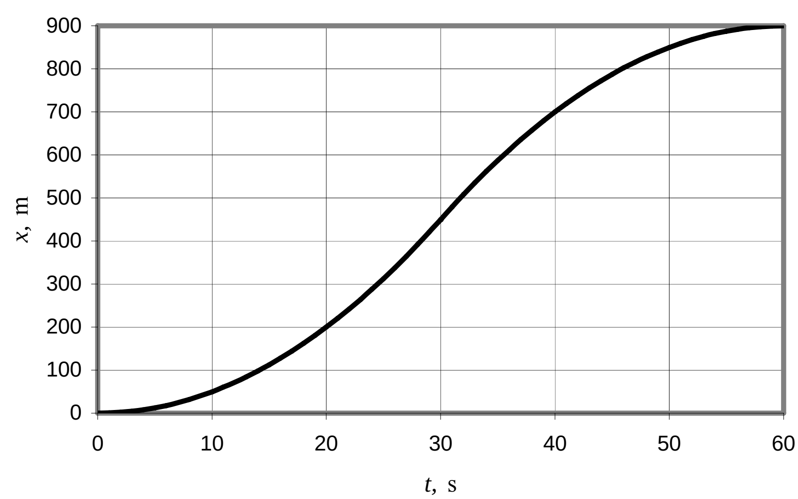
Because the train accelerates uniformly and from rest, the first part of its velocity graph will be linear, pass through the origin, and last for 30 s. Because it slows down uniformly and at the same rate for the second half of its journey, this part of its graph will also be linear but with a negative slope. A graph of v as a function of t follows.



(b) The graph of x as a function of t is obtained from the graph of v as a function of t by finding the area under the velocity curve. Looking at the velocity graph, note that when the train has been in motion for 10 s, it will have traveled a distance of

$$\tfrac{1}{2}(10\,\mathrm{s})(10\,\mathrm{m/s}) = 50\,\mathrm{m}$$

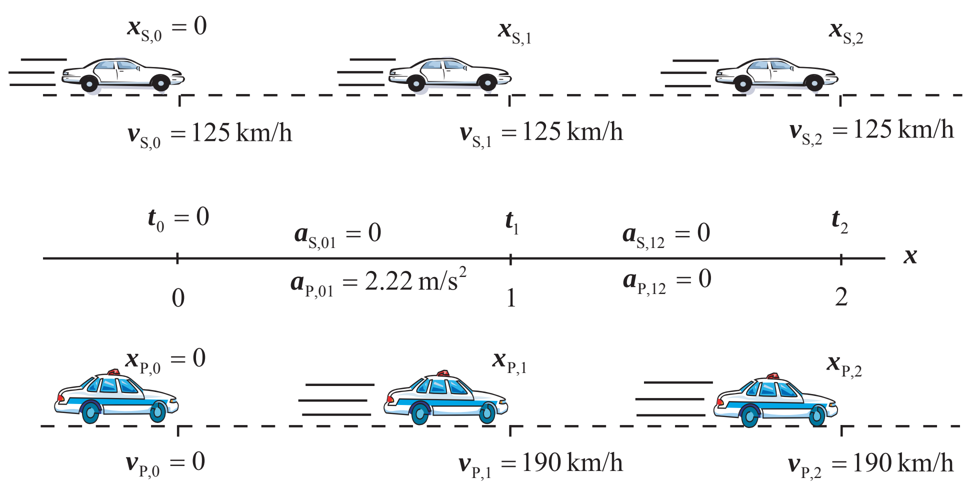
and that this distance is plotted above 10 s on the following graph.



Selecting additional points from the velocity graph and calculating the areas under the curve will confirm the graph of x as a function of t.

99 ••• **[SSM]** A speeder traveling at a constant speed of 125 km/h races past a billboard. A patrol car pursues from rest with constant acceleration of (8.0 km/h)/s until it reaches its maximum speed of 190 km/h, which it maintains until it catches up with the speeder. (*a*) How long does it take the patrol car to catch the speeder if it starts moving just as the speeder passes? (*b*) How far does each car travel? (*c*) Sketch *x*(*t*) for each car.

Picture the Problem This is a two-stage constant-acceleration problem. Choose a coordinate system in which the direction of the motion of the cars is the positive direction. The pictorial representation summarizes what we know about the motion of the speeder's car and the patrol car.



Convert the speeds of the vehicles and the acceleration of the police car into SI units:

$$8.0\frac{\text{km}}{\text{h}\cdot\text{s}} = 8.0\frac{\text{km}}{\text{h}\cdot\text{s}}\times\frac{1\text{ h}}{3600\text{ s}} = 2.2\text{ m/s}^2,$$

$$125\frac{\text{km}}{\text{h}} = 125\frac{\text{km}}{\text{h}}\times\frac{1\text{ h}}{3600\text{ s}} = 34.7\text{ m/s},$$

and

$$190\frac{\text{km}}{\text{h}} = 190\frac{\text{km}}{\text{h}}\times\frac{1\text{ h}}{3600\text{ s}} = 52.8\text{ m/s}$$

(*a*) Express the condition that determines when the police car catches the speeder; that is, that their displacements will be the same:

$$\Delta x_{P,02} = \Delta x_{S,02}$$

Using a constant-acceleration equation, relate the displacement of the patrol car to its displacement while accelerating and its displacement once it reaches its maximum velocity:

$$\begin{aligned}\Delta x_{P,02} &= \Delta x_{P,01} + \Delta x_{P,12}\\ &= \Delta x_{P,01} + v_{P,1}(t_2 - t_1)\end{aligned}$$

Using a constant-acceleration equation, relate the displacement of the speeder to its constant velocity and the time it takes the patrol car to catch it:

$$\Delta x_{\mathrm{S},02} = v_{\mathrm{S},02}\Delta t_{02} = (34.7\ \mathrm{m/s})t_2$$

Calculate the time during which the police car is speeding up:

$$\Delta t_{\mathrm{P},01} = \frac{\Delta v_{\mathrm{P},01}}{a_{\mathrm{P},01}} = \frac{v_{\mathrm{P},1} - v_{\mathrm{P},0}}{a_{\mathrm{P},01}} = \frac{52.8\ \mathrm{m/s} - 0}{2.2\ \mathrm{m/s^2}} = 24\ \mathrm{s}$$

Express the displacement of the patrol car:

$$\Delta x_{\mathrm{P},01} = v_{\mathrm{P},0}\Delta t_{\mathrm{P},01} + \tfrac{1}{2}a_{\mathrm{P},01}\Delta t_{\mathrm{P},01}^2 = 0 + \tfrac{1}{2}(2.2\ \mathrm{m/s^2})(24\ \mathrm{s})^2 = 630\ \mathrm{m}$$

Equate the displacements of the two vehicles:

$$\Delta x_{\mathrm{P},02} = \Delta x_{\mathrm{P},01} + \Delta x_{\mathrm{P},12} = \Delta x_{\mathrm{P},01} + v_{\mathrm{P},1}(t_2 - t_1) = 630\ \mathrm{m} + (52.8\ \mathrm{m/s})(t_2 - 24\ \mathrm{s})$$

Substitute for $\Delta x_{\mathrm{P},02}$ to obtain:

$$(34.7\ \mathrm{m/s})\ t_2 = 630\ \mathrm{m} + (52.8\ \mathrm{m/s})(t_2 - 24\ \mathrm{s})$$

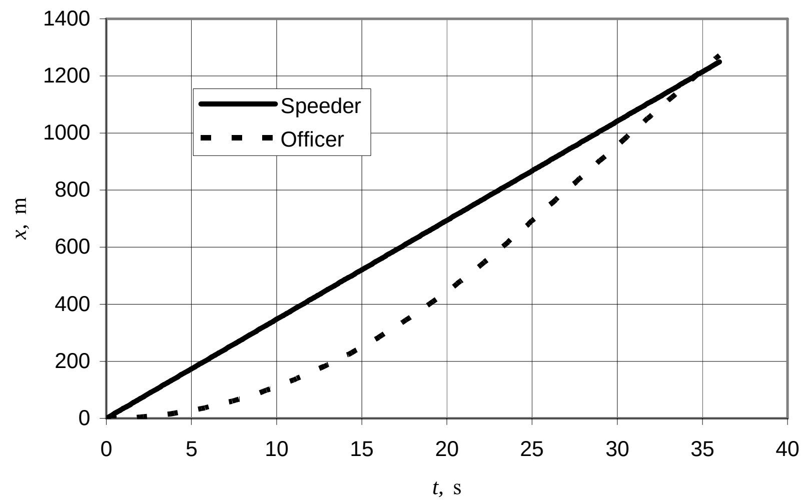
Solving for the time to catch up yields:

$$t_2 = 35.19\ \mathrm{s} = \boxed{35\ \mathrm{s}}$$

(*b*) The distance traveled is the displacement, $\Delta x_{02,\mathrm{S}}$, of the speeder during the catch:

$$\Delta x_{\mathrm{S},02} = v_{\mathrm{S},02}\Delta t_{02} = (35\ \mathrm{m/s})(35.19\ \mathrm{s}) = \boxed{1.2\ \mathrm{km}}$$

(*c*) The graphs of x_S and x_P follow. The straight line (solid) represents $x_S(t)$ and the parabola (dashed) represents $x_P(t)$.



100 ••• When the patrol car in Problem 99 (traveling at 190 km/h), is 100 m behind the speeder (traveling at 125 km/h), the speeder sees the police car and slams on his brakes, locking the wheels. (*a*) Assuming that each car can brake at 6.0 m/s^2 and that the driver of the police car brakes instantly as she sees the brake lights of the speeder (reaction time = 0.0 s), show that the cars collide. (*b*) At what time after the speeder applies his brakes do the two cars collide? (*c*) Discuss how reaction time affects this problem.

Picture the Problem The accelerations of both cars are constant and we can use constant-acceleration equations to describe their motions. Choose a coordinate system in which the direction of motion of the cars is the positive direction, and the origin is at the initial position of the police car.

(*a*) The collision will ***not*** occur if, during braking, the displacements of the two cars differ by less than 100 m:

$$\Delta x_P - \Delta x_S < 100\,\text{m}$$

Using a constant-acceleration equation, relate the speeder's initial and final speeds to its displacement and acceleration and solve for the displacement:

$$v_s^2 = v_{0,s}^2 + 2a_s\Delta x_s$$

or, because $v_S = 0$,

$$\Delta x_s = \frac{-v_{0,s}^2}{2a_s}$$

Substitute numerical values and evaluate Δx_S:

$$\Delta x_S = \frac{-(34.7\,\text{m/s})^2}{2(-6.0\,\text{m/s}^2)} = 100\,\text{m}$$

Using a constant-acceleration equation, relate the patrol car's initial and final speeds to its displacement and acceleration and solve for the displacement:

$v_p^2 = v_{0,p}^2 + 2a_p\Delta x_p$
or, assuming $v_p = 0$,
$\Delta x_p = \dfrac{-v_{0,p}^2}{2a_p}$

Substitute numerical values and evaluate Δx_P:

$$\Delta x_P = \frac{-(52.8\,\text{m/s})^2}{2(-6.0\,\text{m/s}^2)} = 232\,\text{m}$$

Finally, substitute these displacements into the inequality that determines whether a collision occurs:

232 m – 100 m = 132 m
Because this difference is greater than 100 m, $\boxed{\text{the cars collide}}$.

(*b*) Using constant-acceleration equations, relate the positions of both vehicles to their initial positions, initial speeds, accelerations, and time in motion:

$x_S = 100\,\text{m} + (34.7\,\text{m/s})t - (3.0\,\text{m/s}^2)t^2$
and
$x_P = (52.8\,\text{m/s})t - (3.0\,\text{m/s}^2)t^2$

Equate x_S and x_P to obtain:

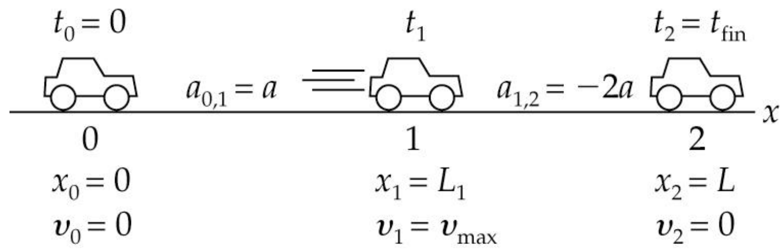
$$100\,\text{m} + (34.7\,\text{m/s})t - (3.0\,\text{m/s}^2)t^2 = (52.8\,\text{m/s})t - (3.0\,\text{m/s}^2)t^2$$

Solving this equation for t yields: $t = \boxed{5.5\,\text{s}}$

(*c*) If you take the reaction time into account, the collision will occur sooner and be more severe.

101 ••• Leadfoot Lou enters the "Rest-to-Rest" auto competition, in which each contestant's car begins and ends at rest, covering a fixed distance L in as short a time as possible. The intention is to demonstrate driving skills, and to find which car is the best at the *total combination* of speeding up and slowing down. The course is designed so that maximum speeds of the cars are never reached. (*a*) If Lou's car maintains an acceleration (magnitude) of a during speedup, and maintains a deceleration (magnitude) of $2a$ during braking, at what fraction of L should Lou move his foot from the gas pedal to the brake? (*b*) What fraction of the total time for the trip has elapsed at that point? (*c*) What is the fastest speed Lou's car ever reaches? Neglect Lou's reaction time, and answer in terms of a and L.

Picture the Problem Lou's acceleration is constant during both parts of his trip. Let t_1 be the time when the brake is applied; L_1 the distance traveled from $t = 0$ to $t = t_1$. Let t_{fin} be the time when Lou's car comes to rest at a distance L from the starting line. A pictorial representation will help organize the given information and plan the solution.



(*a*) Express the total length, L, of the course in terms of the distance over which Lou will be accelerating, Δx_{01}, and the distance over which he will be braking, Δx_{12}:

$$L = \Delta x_{01} + \Delta x_{12} \qquad (1)$$

Express the final speed over the first portion of the course in terms of the initial speed, acceleration, and displacement; solve for the displacement:

$$v_1^2 = v_0^2 + 2a_{01}\Delta x_{01}$$

or, because $v_0 = 0$, $\Delta x_{01} = L_1$, and $a_{01} = a$,

$$\Delta x_{01} = L_1 = \frac{v_1^2}{2a} = \frac{v_{\max}^2}{2a}$$

Express the final speed over the second portion of the course in terms of the initial speed, acceleration, and displacement; solve for the displacement:

$$v_2^2 = v_1^2 + 2a_{12}\Delta x_{12}$$

or, because $v_2 = 0$ and $a_{12} = -2a$,

$$\Delta x_{12} = \frac{v_1^2}{4a} = \frac{L_1}{2}$$

Substitute for Δx_{01} and Δx_{12} to obtain:

$$L = \Delta x_{01} + \Delta x_{12} = L_1 + \tfrac{1}{2}L_1 = \tfrac{3}{2}L_1$$

and

$$L_1 = \boxed{\tfrac{2}{3}L}$$

(*b*) Using the fact that the acceleration was constant during both legs of the trip, express Lou's average speed over each leg:

$$v_{\text{av},01} = v_{\text{av},12} = \frac{v_{\max}}{2}$$

Express the time for Lou to reach his maximum speed as a function of L_1 and his maximum speed:

$$\Delta t_{01} = \frac{\Delta x_{01}}{v_{\text{av},01}} = \frac{2L_1}{v_{\max}}$$

and

$$\Delta t_{01} \propto L_1 = \tfrac{2}{3}L$$

Having just shown that the time required for the first segment of the trip is proportional to the length of the segment, use this result to express Δt_{01} (= t_1) in terms t_{fin}:

$$t_1 = \boxed{\tfrac{2}{3}t_{\text{fin}}}$$

(*c*) Express Lou's displacement during the speeding up portion of his trip:

$$\Delta x_{01} = \tfrac{1}{2}at_1^2$$

The time required for Lou to make this speeding portion of his trip is given by:

$$t_1 = \frac{v_1}{a}$$

Express Lou's displacement during the slowing down portion of his trip:

$$\Delta x_{12} = v_1t_1 - \tfrac{1}{2}(2a)t_2^2 = v_1t_1 - at_2^2$$

where t_2 is his slowing down time.

Substitute in equation (1) to obtain:

$$L = \tfrac{1}{2}at_1^2 + v_1t_1 - at_2^2 \qquad (2)$$

Using a constant-acceleration equation, relate Lou's slowing down time for this portion of his trip to his initial and final speeds:

$$0 = v_1 - 2at_2 \Rightarrow t_2 = \frac{v_1}{2a}$$

Substituting for t_1 and t_2 in equation (2) yields:

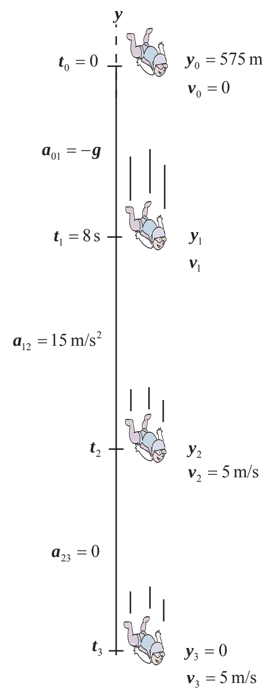
$$L = \tfrac{1}{2}a\left(\frac{v_1}{a}\right)^2 + v_1\left(\frac{v_1}{a}\right) - a\left(\frac{v_1}{2a}\right)^2$$

Solve for v_1 to obtain:

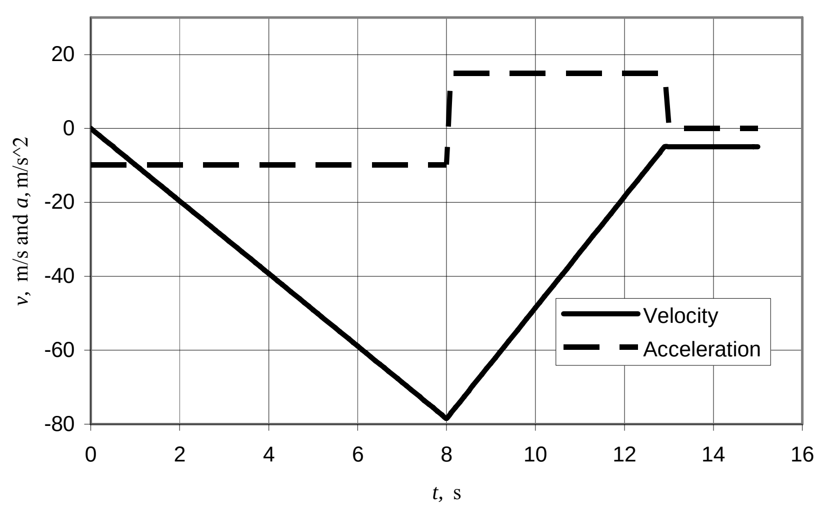
$$v_1 = \boxed{\sqrt{\frac{4aL}{5}}}$$

102 ••• A physics professor, equipped with a rocket backpack, steps out of a helicopter at an altitude of 575 m with zero initial velocity. (Neglect air resistance.) For 8.0 s, she falls freely. At that time she fires her rockets and slows her rate of descent at 15 m/s^2 until her rate of descent reaches 5.0 m/s. At this point she adjusts her rocket engine controls to maintain that rate of descent until she reaches the ground. (*a*) On a single graph, sketch her acceleration and velocity as functions of time. (Take upward to be positive.) (*b*) What is her speed at the end of the first 8.0 s? (*c*) What is the duration of her slowing down period? (*d*) How far does she travel while slowing down? (*e*) How much time is required for the entire trip from the helicopter to the ground? (*f*) What is her average velocity for the entire trip?

Picture the Problem There are three intervals of constant acceleration described in this problem. Choose a coordinate system in which the upward direction is positive. The pictorial representation summarizes the information we are given. We can apply constant-acceleration equations to find her speeds and distances traveled at the end of each phase of her descent.



(a) The graphs of $a(t)$ (dashed lines) and $v(t)$ (solid lines) follow.



(b) Use a constant- acceleration equation to express her speed in terms of her acceleration and the elapsed time:

$$v_1 = v_0 + a_{01}t_1$$

or, because $a_{01} = -g$ and $v_0 = 0$,

$$v_1 = -gt_1$$

Substitute numerical values and evaluate v_1:

$$v_1 = \left(-9.81\ \text{m/s}^2\right)\left(8.0\ \text{s}\right) = -78.5\ \text{m/s}$$

and her speed is $\boxed{79\ \text{m/s}}$

(*c*) As in (*b*), use a constant-acceleration equation to express her speed in terms of her acceleration and the elapsed time:

$$v_2 = v_1 + a_{12}\Delta t_{12} \Rightarrow \Delta t_{12} = \frac{v_2 - v_1}{a_{12}}$$

Substitute numerical values and evaluate Δt_{12}:

$$\Delta t_{12} = \frac{-5.0\,\text{m/s} - (-78.5\,\text{m/s})}{15\,\text{m/s}^2} = \boxed{4.9\,\text{s}}$$

(*d*) Find her average speed as she slows from 78.5 m/s to 5 m/s:

$$v_{\text{av}} = \frac{v_1 + v_2}{2} = \frac{78.5\,\text{m/s} + 5.0\,\text{m/s}}{2} = 41.7\,\text{m/s}$$

Use this value to calculate how far she travels in 4.90 s:

$$\Delta y_{12} = v_{\text{av}}\Delta t_{12} = (41.7\ \text{m/s})(4.90\,\text{s}) = 204.3\,\text{m}$$

She travels approximately 204 m while slowing down.

(*e*) Express the total time in terms of the times for each segment of her descent:

$$\Delta t_{\text{total}} = \Delta t_{01} + \Delta t_{12} + \Delta t_{23}$$

We know the times for the intervals from 0 to 1 and 1 to 2 so we only need to determine the time for the interval from 2 to 3. We can calculate Δt_{23} from her displacement and constant speed during that segment of her descent.

$$\Delta y_{23} = \Delta y_{\text{total}} - \Delta y_{01} - \Delta y_{12} = 575\,\text{m} - \left(\frac{78.5\,\text{m/s}}{2}\right)(8.0\,\text{s}) - 204.3\,\text{m} = 56.7\,\text{m}$$

Add the times to get the total time:

$$\Delta t_{\text{total}} = \Delta t_{01} + \Delta t_{12} + \Delta t_{23} = 8.0\,\text{s} + 4.9\,\text{s} + \frac{56.7\,\text{m}}{5.0\,\text{m/s}} = 24.24\,\text{s} = \boxed{24\,\text{s}}$$

(*f*) Using its definition, calculate her average velocity:

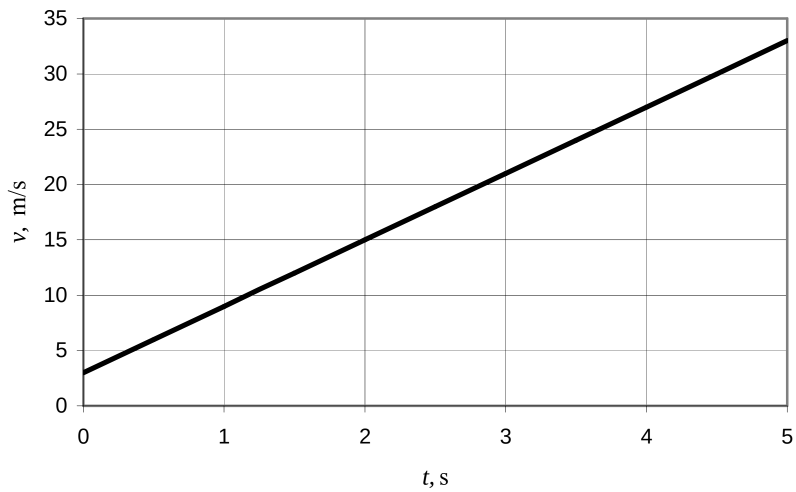
$$v_{\text{av}} = \frac{\Delta y}{\Delta t_{\text{total}}} = \frac{-575\,\text{m}}{24.24\,\text{s}} = \boxed{-24\,\text{m/s}}$$

Integration of the Equations of Motion

103 • [SSM] The velocity of a particle is given by $v_x(t) = (6.0\text{ m/s}^2)t + (3.0\text{ m/s})$. (*a*) Sketch *v* versus *t* and find the area under the curve for the interval $t = 0$ to $t = 5.0$ s. (*b*) Find the position function $x(t)$. Use it to calculate the displacement during the interval $t = 0$ to $t = 5.0$ s.

Picture the Problem The integral of a function is equal to the "area" between the curve for that function and the independent-variable axis.

(*a*) The following graph was plotted using a spreadsheet program:



The distance is found by determining the area under the curve. There are approximately 18 blocks each having an area of

$(5.0\text{ m/s})(1.0\text{ s}) = 5.0\text{ m}.$

$$A_{\substack{\text{under}\\\text{curve}}} = (18\text{ blocks})(5.0\text{ m/block}) = \boxed{90\text{ m}}$$

You can confirm this result by using the formula for the area of a trapezoid:

$$A = \left(\frac{33\text{ m/s} + 3\text{ m/s}}{2}\right)(5.0\text{ s} - 0\text{ s}) = 90\text{ m}$$

(*b*) To find the position function $x(t)$, we integrate the velocity function $v(t)$ over the time interval in question:

$$x(t) = \int_0^t v(t)\,\mathrm{d}t = \int_0^t \left[(6.0\text{ m/s}^2)t + (3.0\text{ m/s})\right] dt$$

and

$$x(t) = \boxed{(3.0\text{ m/s}^2)t^2 + (3.0\text{ m/s})\,t}$$

Now evaluate $x(t)$ at 0 s and 5.0 s respectively and subtract to obtain Δx:

$$\Delta x = x(5.0\,\text{s}) - x(0\,\text{s}) = 90\text{ m} - 0\text{ m}$$
$$= \boxed{90\text{ m}}$$

104 • Figure 2-41 shows the velocity of a particle versus time. (*a*) What is the magnitude in meters represented by the area of the shaded box? (*b*) Estimate the displacement of the particle for the two 1-s intervals, one beginning at $t = 1.0$ s and the other at $t = 2.0$ s. (*c*) Estimate the average velocity for the interval $1.0\text{ s} \le t \le 3.0\text{ s}$. (*d*) The equation of the curve is $v_x = (0.50\text{ m/s}^3)t^2$. Find the displacement of the particle for the interval $1.0\text{ s} \le t \le 3.0\text{ s}$ by integration and compare this answer with your answer for Part (*b*). Is the average velocity equal to the mean of the initial and final velocities for this case?

Picture the Problem The integral of $v(t)$ over a time interval is the displacement (change in position) during that time interval. The integral of a function is equivalent to the "area" between the curve for that function and the independent-variable axis. Count the grid boxes.

(*a*) Find the area of the shaded grid box:

$$\text{Area} = (1\text{ m/s})(1\text{ s}) = \boxed{1\text{ m per box}}$$

(*b*) Find the approximate area under the curve for $1.0\text{ s} \le t \le 2.0\text{ s}$:

$$\Delta x_{1.0\text{ s to }2.0\text{ s}} = \boxed{1.2\text{ m}}$$

Find the approximate area under the curve for $2.0\text{ s} \le t \le 3.0\text{ s}$:

$$\Delta x_{2.0\text{ s to }3.0\text{ s}} = \boxed{3.2\text{ m}}$$

(*c*) Sum the displacements to obtain the total in the interval $1.0\text{ s} \le t \le 3.0\text{ s}$:

$$\Delta x_{1.0\text{ s to }3.0\text{ s}} = 1.2\text{ m} + 3.2\text{ m}$$
$$= 4.4\text{ m}$$

Using its definition, express and evaluate v_{av}:

$$v_{av} = \frac{\Delta x_{1.0\text{ s to }3.0\text{ s}}}{\Delta t_{1.0\text{ s to }3.0\text{ s}}} = \frac{4.4\text{ m}}{2.0\text{ s}} = \boxed{2.2\text{ m/s}}$$

(*d*) Because the velocity of the particle is dx/dt, separate the variables and integrate over the interval 1.0 s ≤ t ≤ 3.0 s to determine the displacement in this time interval:

$$dx = \left(0.50\ \text{m/s}^3\right)t^2 dt$$

so

$$\Delta x_{1.0\,\text{s}\to 3.0\,\text{s}} = \int_{x_0}^{x} dx = \left(0.50\ \text{m/s}^3\right)\int_{1.0\ \text{s}}^{3.0\ \text{s}} t^2 dt$$

$$= \left(0.50\,\text{m/s}^3\right)\left[\frac{t^3}{3}\right]_{1.0\text{s}}^{3.0\text{s}} = 4.33\ \text{m}$$

$$= \boxed{4.3\ \text{m}}$$

This result is a little smaller than the sum of the displacements found in Part (*b*).

Calculate the average velocity over the 2-s interval from 1.0 s to 3.0 s:

$$v_{\text{av}\,(1.0\text{s}-3.0\text{s})} = \frac{\Delta x_{1.0\text{s}-3.0\text{s}}}{\Delta t_{1.0\text{s}-3.0\text{s}}} = \frac{4.33\ \text{m}}{2.0\ \text{s}} = 2.2\ \text{m/s}$$

Calculate the initial and final velocities of the particle over the same interval:

$$v(1.0\,\text{s}) = \left(0.50\,\text{m/s}^3\right)(1.0\,\text{s})^2 = 0.50\ \text{m/s}$$

$$v(3.0\,\text{s}) = \left(0.50\,\text{m/s}^3\right)(3.0\,\text{s})^2 = 4.5\ \text{m/s}$$

Finally, calculate the average value of the velocities at t = 1.0 s and t = 3.0 s:

$$\frac{v(1.0\,\text{s}) + v(3.0\,\text{s})}{2} = \frac{0.50\ \text{m/s} + 4.5\ \text{m/s}}{2}$$

$$= 2.5\ \text{m/s}$$

This average of 2.5 m/s is not equal to the average velocity calculated above because this is not an example of constant acceleration.

105 •• The velocity of a particle is given by $v_x = (7.0\ \text{m/s}^3)t^2 - 5.0\ \text{m/s}$, where t is in seconds and v is in meters per second. If the particle is at the origin at $t_0 = 0$, find the position function $x(t)$.

Picture the Problem Because the velocity of the particle varies with the square of the time, the acceleration is not constant. The position of the particle is found by integrating the velocity function.

Express the velocity of a particle as the derivative of its position function:

$$v(t) = \frac{dx(t)}{dt}$$

Separate the variables to obtain:

$$dx(t) = v(t)dt$$

Express the integral of x from $x_o = 0$ to x and t from $t_0 = 0$ to t:

$$x(t) = \int_{t_0=0}^{x(t)} dx = \int_{t_0=0}^{t} v(t)dt$$

Substitute for $v(t)$ and carry out the integration to obtain:

$$x(t) = \int_{t_0=0}^{t} \left[\left(7.0\,\text{m/s}^3\right)t^2 - \left(5.0\,\text{m/s}\right)\right]dt$$
$$= \boxed{\left(2.3\,\text{m/s}^3\right)t^3 - \left(5.0\,\text{m/s}\right)t}$$

106 •• Consider the velocity graph in Figure 2-42. Assuming $x = 0$ at $t = 0$, write correct algebraic expressions for $x(t)$, $v_x(t)$, and $a_x(t)$ with appropriate numerical values inserted for all constants.

Picture the Problem The graph is one of constant negative acceleration. Because $v_x = v(t)$ is a linear function of t, we can make use of the slope-intercept form of the equation of a straight line to find the relationship between these variables. We can then differentiate $v(t)$ to obtain $a(t)$ and integrate $v(t)$ to obtain $x(t)$.

Find the acceleration (the slope of the graph) and the velocity at time 0 (the v-intercept) and use the slope-intercept form of the equation of a straight line to express $v_x(t)$:

$$a_x = \boxed{-10\,\text{m/s}^2}$$
and
$$v_x(t) = \boxed{50\,\text{m/s} + (-10\,\text{m/s}^2)t}$$

Find $x(t)$ by integrating $v(t)$:

$$x(t) = \int \left[\left(-10\,\text{m/s}^2\right)t + 50\,\text{m/s}\right]dt$$
$$= \left(50\,\text{m/s}\right)t - \left(5.0\,\text{m/s}^2\right)t^2 + \text{C}$$

Using the fact that $x = 0$ when $t = 0$, evaluate C:

$$0 = \left(50\,\text{m/s}\right)(0) - \left(5.0\,\text{m/s}^2\right)(0)^2 + \text{C}$$
and
C = 0

Substitute to obtain:

$$x(t) = \boxed{\left(50\,\text{m/s}\right)t - \left(5.0\,\text{m/s}^2\right)t^2}$$

Note that this expression is quadratic in t and that the coefficient of t^2 is negative and equal in magnitude to half the constant acceleration.

Remarks: We can check our result for $x(t)$ by evaluating it over the 10-s interval shown and comparing this result with the area bounded by this curve and the time axis.

107 ••• Figure 2-43 shows the acceleration of a particle versus time. (*a*) What is the magnitude, in m/s, of the area of the shaded box? (*b*) The particle starts from rest at $t = 0$. Estimate the velocity at $t = 1.0$ s, 2.0 s, and 3.0 s by counting the boxes under the curve. (*c*) Sketch the curve v versus t from your results for Part (*b*), then estimate how far the particle travels in the interval $t = 0$ to $t = 3.0$ s using your curve.

Picture the Problem During any time interval, the integral of $a(t)$ is the change in velocity and the integral of $v(t)$ is the displacement. The integral of a function equals the "area" between the curve for that function and the independent-variable axis.

(*a*) Find the area of the shaded grid box in Figure 2-44:

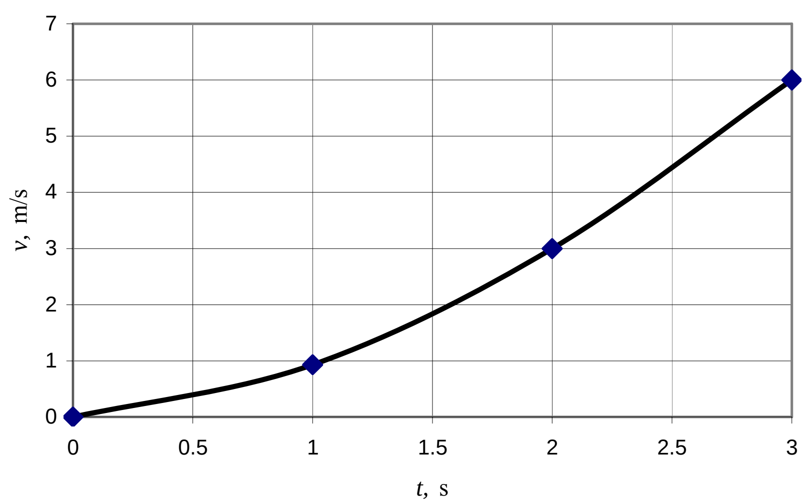
$$Area = \left(0.50\,\frac{\text{m}}{\text{s}^2}\right)(0.50\text{ s})$$

$$= \boxed{0.25\text{ m/s per box}}$$

(*b*) We start from rest ($v_0 = 0$) at $t = 0$. For the velocities at the other times, count boxes and multiply by the 0.25 m/s per box that we found in Part (*a*):

t	# of boxes	$v(t)$
(s)		(m/s)
1.0	3.7	$\boxed{0.93\text{ m/s}}$
2.0	12	$\boxed{3.0\text{ m/s}}$
3.0	24	$\boxed{6.0\text{ m/s}}$

(*c*) The graph of v as a function of t follows:



$$Area = hw = (1.0\text{ m/s})(0.50\text{ s}) = 0.50\text{ m per box}$$

Count the boxes under the $v(t)$ curve to find the distance traveled:

$$x(3.0\,\text{s}) = \Delta x(0 \to 3.0\,\text{s}) = (13\,\text{boxes})[(0.50\,\text{m})/\text{box}] = \boxed{6.5\,\text{m}}$$

108 ••• Figure 2-44 is a graph of v_x versus t for a particle moving along a straight line. The position of the particle at time $t = 0$ is $x_0 = 5.0$ m. (*a*) Find x for various times t by counting boxes, and sketch x as a function of t. (*b*) Sketch a graph of the acceleration a as a function of the time t. (*c*) Determine the displacement of the particle between $t = 3.0$ s and 7.0 s.

Picture the Problem The integral of $v(t)$ over a time interval is the displacement (change in position) during that time interval. The integral of a function equals the "area" between the curve for that function and the independent-variable axis. We can estimate this value by counting the number of squares under the curve between given limits and multiplying this count by the "area" of each square. Because acceleration is the slope of a velocity versus time curve, this is a non-constant-acceleration problem. The derivative of a function is equal to the "slope" of the function at that value of the independent variable. We can approximate the slope of any graph by drawing tangent lines and estimating their slopes.

(*a*) To obtain the data for $x(t)$, we must estimate the accumulated area under the $v(t)$ curve at each time interval:

Find the area of a shaded grid box in Figure 2-44:

$$\text{Area} = hw = (1.0\text{ m/s})(0.50\text{ s}) = 0.50\text{ m per box}$$

We start from rest ($v_o = 0$) at $t_o = 0$. For the position at the other times, count boxes and multiply by the 0.50 m per box that we found above. Remember to add the offset from the origin, $x_o = 5.0$ m, and that boxes below the $v = 0$ line are counted as negative:

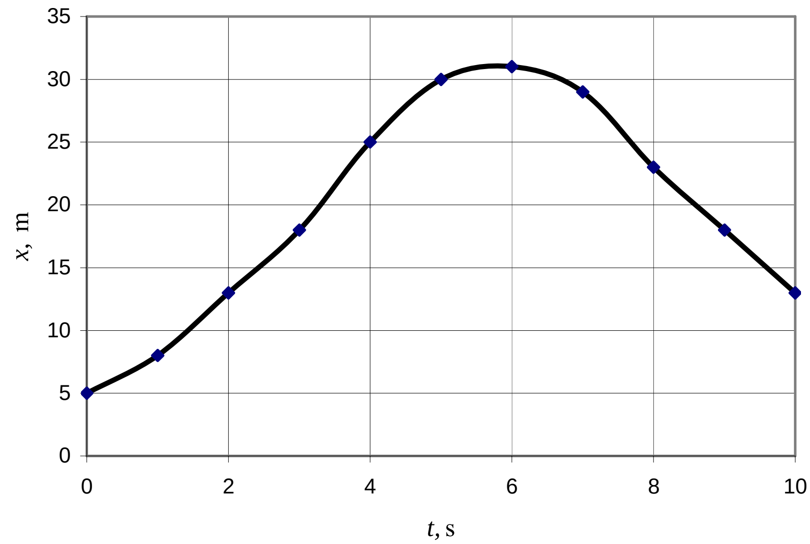
Examples:

$$x(2\,\text{s}) = (15.5\,\text{boxes})\left(\frac{0.50\text{ m}}{\text{box}}\right) + 5.0\,\text{m} = 13\text{ m}$$

$$x(5\,\text{s}) = (49\text{ boxes})\left(\frac{0.50\text{ m}}{\text{box}}\right) + 5.0\text{ m} = 30\text{ m}$$

$$x(10\,\text{s}) = (51\,\text{boxes})\left(\frac{0.50\text{ m}}{\text{box}}\right) - (36\,\text{boxes})\left(\frac{0.50\text{ m}}{\text{box}}\right) + 5.0\text{ m} = 13\text{ m}$$

A graph of x as a function of t follows:



(b) To obtain the data for $a(t)$, we must estimate the slope ($\Delta v/\Delta t$) of the $v(t)$ curve at several times. A good way to get reasonably reliable readings from the graph is to enlarge it several fold and then estimate the slope of the tangent line at selected points on the graph:

Examples:

$$a(2\text{ s}) = \frac{8.0\text{ m/s} - 4.1\text{ m/s}}{4.9\text{ s}} = 0.8\text{ m/s}^2$$

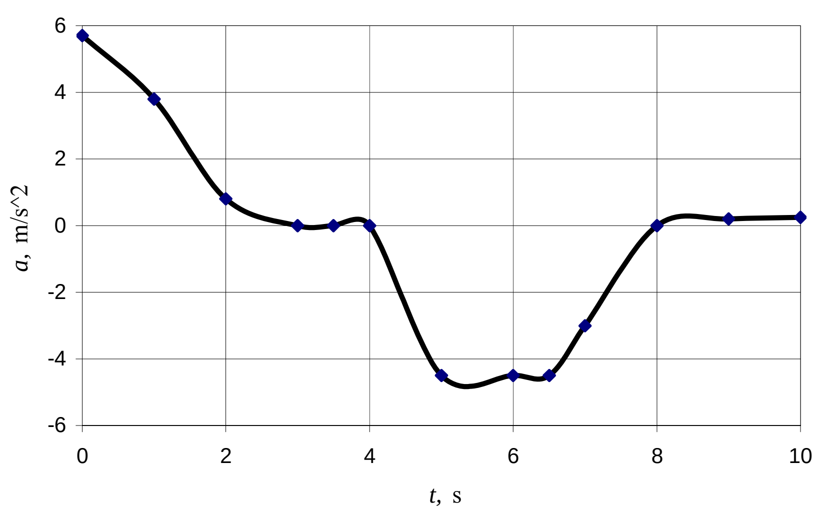
$$a(3\text{ s}) = 0$$

$$a(5\text{ s}) = \frac{-6.0\text{ m/s} - 8.0\text{ m/s}}{7.1\text{ s} - 4.0\text{ s}} = -4.5\text{ m/s}^2$$

$$a(7\text{ s}) = \frac{-6.0\text{ m/s} - 1.4\text{ m/s}}{7.6\text{ s} - 5.0\text{ s}} = -3.0\text{ m/s}^2$$

$$a(8\text{ s}) = 0$$

A graph of a as a function of t follows:



(*c*) The displacement of the particle between t = 3.0 s and 7.0 s is given by:

$$\Delta x_{3.0\,\text{s}\to 7.0\,\text{s}} = x(7.0\ \text{s}) - x(3.0\ \text{s})$$

Use the graph in (*a*) to obtain:

$$x(7.0\ \text{s}) = 29\ \text{m and } x(3.0\ \text{s}) = 18\ \text{m}$$

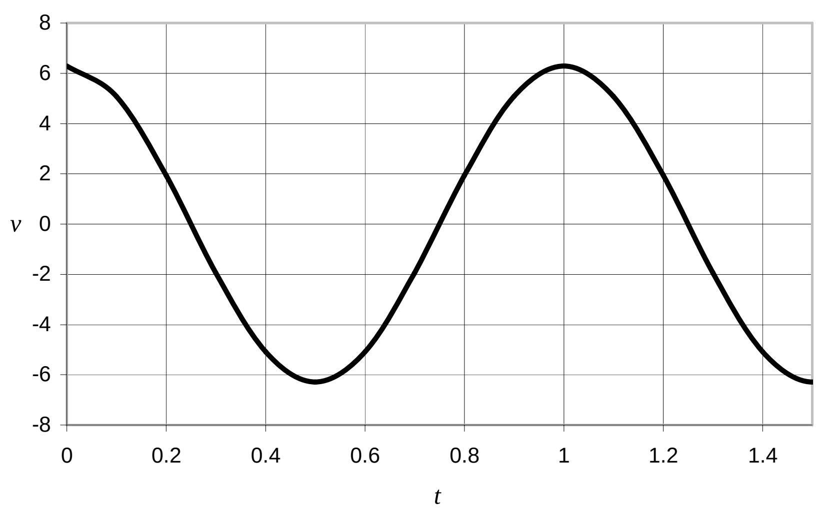
Substitute for Δx(7.0 s) and Δx(3.0 s) to obtain:

$$\Delta x_{3.0\,\text{s}\to 7.0\,\text{s}} = 29\ \text{m} - 18\ \text{m} = \boxed{11\ \text{m}}$$

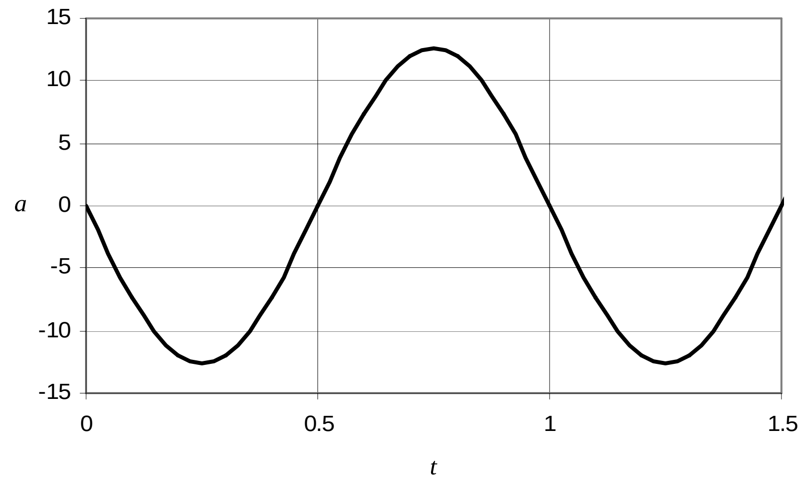
109 ••• [SSM] Figure 2-45 shows a plot of x versus t for a body moving along a straight line. For this motion, sketch graphs (using the same t axis) of (*a*) v_x as a function of t, and (*b*) a_x as a function of t. (*c*) Use your sketches to qualitatively compare the time(s) when the object is at its largest distance from the origin to the time(s) when its speed is greatest. Explain why the times are *not* the same. (*d*) Use your sketches to qualitatively compare the time(s) when the object is moving fastest to the time(s) when its acceleration is the largest. Explain why the times are *not* the same.

Picture the Problem Because the position of the body is not described by a parabolic function, the acceleration is not constant.

(*a*) Select a series of points on the graph of $x(t)$ (e.g., at the extreme values and where the graph crosses the t axis), draw tangent lines at those points, and measure their slopes. In doing this, you are evaluating $v = dx/dt$ at these points. Plot these slopes above the times at which you measured the slopes. Your graph should closely resemble the following graph.



(*b*) Select a series of points on the graph of $v(t)$ (e.g., at the extreme values and where the graph crosses the t axis), draw tangent lines at those points, and measure their slopes. In doing this, you are evaluating $a = dv/dt$ at these points. Plot these slopes above the times at which you measured the slopes. Your graph should closely resemble the following graph.



(c) The points at the greatest distances from the time axis correspond to turn-around points. The velocity of the body is zero at these points.

(d) The body is moving fastest as it goes through the origin. At these times the velocity is not changing and hence the acceleration is zero. The maximum acceleration occurs at the maximum distances where the velocity is zero but changing direction rapidly.

110 ••• The acceleration of a certain rocket is given by $a = bt$, where b is a positive constant. (a) Find the position function $x(t)$ if $x = x_0$ and $v_x = v_{0x}$ at $t = 0$. (b) Find the position and velocity at $t = 5.0$ s if $x_0 = 0$, $v_{0x} = 0$ and $b = 3.0$ m/s^3. (c) Compute the average velocity of the rocket between $t = 4.5$ s and 5.5 s at $t = 5.0$ s if $x_0 = 0$, $v_{0x} = 0$ and $b = 3.0$ m/s^3. Compare this average velocity with the instantaneous velocity at $t = 5.0$ s.

Picture the Problem Because the acceleration of the rocket varies with time, it is not constant and integration of this function is required to determine the rocket's velocity and position as functions of time. The conditions on x and v at $t = 0$ are known as ***initial conditions***.

(a) Integrate $a(t)$ to find $v(t)$:

$$v(t) = \int a(t)\,dt = b\int t\,dt = \tfrac{1}{2}bt^2 + \mathrm{C}$$

where C, the constant of integration, can be determined from the initial conditions.

Integrate $v(t)$ to find $x(t)$:

$$x(t) = \int v(t)dt = \int\left[\tfrac{1}{2}bt^2 + \mathrm{C}\right]dt$$

$$= \tfrac{1}{6}bt^3 + \mathrm{C}t + \mathrm{D}$$

where D is a second constant of integration.

Using the initial conditions, find the constants C and D:

$v_x(0) = v_{0x} \Rightarrow C = v_{0x}$
and
$x(0) = x_0 \Rightarrow D = x_0$
and so
$x(t) = \boxed{\tfrac{1}{6}bt^3 + v_{0x}t + x_0}$

(*b*) Evaluate $v(5.0\text{ s})$ and $x(5.0\text{ s})$ with C = D = 0 and $b = 3.0\text{ m/s}^3$:

$v(5.0\,\text{s}) = \tfrac{1}{2}(3.0\text{ m/s}^3)(5.0\text{ s})^2 = \boxed{38\,\text{m/s}}$
and
$x(5.0\,\text{s}) = \tfrac{1}{6}(3.0\text{ m/s}^3)(5.0\text{ s})^3 = \boxed{63\,\text{m}}$

(*c*) The average value of $v(t)$ over the interval Δt is given by:

$$\bar{v} = \frac{1}{\Delta t}\int_{t_1}^{t_2} v(t)dt$$

Substitute for Δt and $v(t)$ and evaluate the integral to obtain:

$$\bar{v} = \frac{1}{\Delta t}\int_{t_1}^{t_2} \tfrac{1}{2}bt^2dt = \frac{b}{6\Delta t}t^3\Big|_{t_1}^{t_2} = \frac{b(t_2^3 - t_1^3)}{6\Delta t}$$

Substitute numerical values and evaluate $\bar{v}$:

$$\bar{v} = \frac{(3.0\text{ m/s}^3)\left[(5.5\text{ s})^3 - (4.5\text{ s})^3\right]}{6(5.5\text{ s} - 4.5\text{ s})}$$

$= \boxed{38\text{ m/s}}$ ... a result in good agreement with the value found in (*b*).

111 ••• [SSM] In the time interval from 0.0 s to 10.0 s, the acceleration of a particle traveling in a straight line is given by $a_x = (0.20\text{ m/s}^3)t$. Let to the right be the $+x$ direction. The particle initially has a velocity to the right of 9.5 m/s and is located 5.0 m to the left of the origin. (*a*) Determine the velocity as a function of time during the interval, (*b*) determine the position as a function of time during the interval, (*c*) determine the average velocity between $t = 0.0$ s and10.0 s, and compare it to the average of the instantaneous velocities at the start and ending times. Are these two averages equal? Explain.

Picture the Problem The acceleration is a function of time; therefore it is not constant. The instantaneous velocity can be determined by integration of the acceleration function and the average velocity from the general expression for the average value of a non-linear function.

(*a*) The ***instantaneous velocity*** function $v(t)$ is the time-integral of the acceleration function:

$$v(t) = \int a_x dt = \int bt\,dt = \frac{b}{2}t^2 + C_1$$

where $b = 0.20\text{ m/s}^3$

The initial conditions are: 1) $x(0) = -5.0\text{ m}$ and 2) $v(0) = 9.5\text{ m/s}$

Use initial condition 2) to obtain: $v(0) = 9.5\text{ m/s} = C_1$

Substituting in $v(t)$ for b and C_1 yields: $v(t) = \boxed{\left(0.10\text{ m/s}^3\right)t^2 + 9.5\text{ m/s}}$ (1)

(*b*) The ***instantaneous position*** function $x(t)$ is the time-integral of the velocity function:

$$x(t) = \int v(t)dt = \int\left(ct^2 + C_1\right)dt$$

$$= \frac{c}{3}t^3 + C_1 t + C_2$$

where $c = 0.10\text{ m/s}^3$.

Using initial condition 1) yields: $x(0) = -5.0\text{ m} = C_2$

Substituting in $x(t)$ for C_1 and C_2 yields:

$$x(t) = \boxed{\tfrac{1}{3}\left(0.20\text{ m/s}^3\right)t^3 + (9.5\text{ m/s})t - 5.0\text{ m/s}}$$

(*c*) The average value of $v(t)$ over the interval Δt is given by:

$$\bar{v} = \frac{1}{\Delta t}\int_{t_1}^{t_2} v(t)dt$$

Substitute for $v(t)$ and evaluate the integral to obtain:

$$\bar{v} = \frac{1}{\Delta t}\int_{t_1}^{t_2}\left(\frac{b}{2}t^2 + C_1\right)dt = \frac{1}{\Delta t}\left[\frac{b}{6}t^3 + C_1 t\right]_{t_1}^{t_2} = \frac{1}{\Delta t}\left[\frac{b}{6}t_2^3 + C_1 t_2 - \left(\frac{b}{6}t_1^3 + C_1 t_1\right)\right]$$

Simplifying this expression yields:

$$\bar{v} = \frac{1}{\Delta t}\left[\frac{b}{6}\left(t_2^3 - t_1^3\right) + C_1\left(t_2 - t_1\right)\right]$$

Because $t_1 = 0$:

$$\bar{v} = \frac{1}{\Delta t}\left[\frac{b}{6}t_2^3 + C_1 t_2\right]$$

Substitute numerical values and simplify to obtain:

$$\bar{v} = \frac{1}{10.0\text{ s}}\left[\left(\frac{0.20\text{ m/s}^3}{6}\right)(10.0\text{ s})^3 + (9.5\text{ m/s})(10.0\text{ s})\right] = \boxed{13\text{ m/s}}$$

The average of the initial instantaneous and final instantaneous velocities is given by:

$$v_{\text{av}} = \frac{v(0) + v(10.0\text{ s})}{2} \qquad (2)$$

Using equation (1), evaluate $v(0)$ and $v(10\text{ s})$:

$$v(0) = 9.5\text{ m/s}$$

and

$$v(10\text{ s}) = (0.10\text{ m/s}^3)(10.0\text{ s})^2 + 9.5\text{ m/s}$$
$$= 19.5\text{ m/s}$$

Substitute in equation (2) to obtain:

$$v_{\text{av}} = \frac{9.5\text{ m/s} + 19.5\text{ m/s}}{2} = \boxed{15\text{ m/s}}$$

v_{av} is not the same as $\bar{v}$ because the velocity does not change linearly with time. The velocity does not change linearly with time because the acceleration is not constant.

112 ••• Consider the motion of a particle that experiences a variable acceleration given by $a_x = a_{0x} + bt$, where a_{0x} and b are constants and $x = x_0$ and $v_x = v_{0x}$ at $t = 0$. (*a*) Find the instantaneous velocity as a function of time. (*b*) Find the position as a function of time. (*c*) Find the average velocity for the time interval with an initial time of zero and arbitrary final time t. (*d*) Compare the average of the initial and final velocities to your answer to Part (*c*). Are these two averages equal? Explain.

Determine the Concept Because the acceleration is a function of time, it is not constant. Hence we'll need to integrate the acceleration function to find the velocity of the particle as a function of time and integrate the velocity function to find the position of the particle as a function of time. We can use the general expression for the average value of a non-linear function to find the average velocity over an arbitrary interval of time.

(*a*) From the definition of acceleration we have:

$$\int_{v_{0x}}^{v_x} dv = \int_0^t a\,dt$$

Integrating the left-hand side of the equation and substituting for a on the right-hand side yields:

$$v_x - v_{0x} = \int_0^t (a_0 + bt)\,dt$$

Integrate the right-hand side to obtain:

$$v_x - v_{0x} = a_0 t + \tfrac{1}{2}bt^2$$

Solving this equation for v_x yields:

$$v_x = \boxed{v_{0x} + a_0 t + \tfrac{1}{2}bt^2} \qquad (1)$$

(*b*) The position of the particle as a function of time is the integral of the velocity function:

$$\int_{x_0}^{x} dx = \int_0^t v_x(t)dt$$

Integrating the left-hand side of the equation and substituting for *a* on the right-hand side yields:

$$x - x_0 = \int_0^t \left(v_{0x} + a_0 t + \frac{b}{2}t^2 \right) dt$$

Integrate the right-hand side to obtain:

$$x - x_0 = v_{0x}t + \tfrac{1}{2}a_0 t^2 + \tfrac{1}{6}bt^3$$

Solving this equation for *x* yields:

$$x = \boxed{x_{0x} + v_0 t + \tfrac{1}{2}a_0 t^2 + \tfrac{1}{6}bt^3}$$

(*c*) The average value of $v(t)$ over an interval Δt is given by:

$$\bar{v}_x = \frac{1}{\Delta t}\int_{t_1}^{t_2} v_x(t)dt$$

or, because $t_1 = 0$ and $t_2 = t$,

$$\bar{v}_x = \frac{1}{t}\int_0^t v_x(t)dt$$

Substituting for $v_x(t)$ yields:

$$\bar{v}_x = \frac{1}{t}\int_0^t \left(v_{0x} + a_0 t + \tfrac{1}{2}bt^2 \right) dt$$

Carry out the details of the integration to obtain:

$$\bar{v}_x = \frac{1}{t}\left[v_{0x}t + \tfrac{1}{2}a_0 t^2 + \tfrac{1}{6}bt^3 \right]_0^t$$

$$= \frac{1}{t}\left[v_{0x}t + \tfrac{1}{2}a_0 t^2 + \tfrac{1}{6}bt^3 \right]$$

$$= \boxed{v_{0x} + \tfrac{1}{2}a_0 t + \tfrac{1}{6}bt^2}$$

(*d*) The average of the initial instantaneous and final instantaneous velocities is given by:

$$v_{\text{av},x} = \frac{v_{0x} + v_x}{2}$$

Using equation (1), substitute to obtain:

$$v_{\text{av},x} = \frac{v_{0x} + v_{0x} + a_0 t + \tfrac{1}{2}bt^2}{2}$$

$$= \frac{2v_{0x} + a_0 t + \tfrac{1}{2}bt^2}{2}$$

$$= \boxed{v_{0x} + \tfrac{1}{2}a_0 t + \tfrac{1}{4}bt^2}$$

$v_{\text{av},x}$ is not the same as $\bar{v}_x$ because the acceleration is not constant.

General Problems

113 ••• You are a student in a science class that is using the following apparatus to determine the value of g. Two photogates are used. (Note: You may be familiar with photogates in everyday living. You see them in the doorways of some stores. They are designed to ring a bell when someone interrupts the beam while walking through the door.) One photogate is located at the edge of a table that is 1.00 m above the floor, and the second photogate is located directly below the first, at a height 0.500 m above the floor. You are told to drop a marble through these gates, releasing it from rest a negligible distance above the upper gate. The upper gate starts a timer as the marble passes through its beam. The second photogate stops the timer when the marble passes through its beam. (*a*) Prove that the experimental magnitude of free-fall acceleration is given by $g_{exp} = (2\Delta y)/(\Delta t)^2$, where Δy is the vertical distance between the photogates and Δt is the fall time. (*b*) For your setup, what value of Δt would you expect to measure, assuming g_{exp} is the value (9.81 m/s^2)? (*c*) During the experiment, a slight error is made. Instead of locating the first photogate even with the top of the table, your not-so-careful lab partner locates it 0.50 cm lower than the top of the table. However, she releases the marble from the same height that it was released from when the photogate was 1.00 m above the floor. What value of g_{exp} will you and your partner determine? What percentage difference does this represent from the standard value at sea level?

Picture the Problem The acceleration of the marble is constant. Because the motion is downward, choose a coordinate system with downward as the positive direction and use constant-acceleration equations to describe the motion of the marble.

(*a*) Use a constant-acceleration equation to relate the vertical distance the marble falls to its time of fall and its free-fall acceleration:

$$\Delta y = v_0\Delta t + \tfrac{1}{2}g_{exp}(\Delta t)^2$$

or, because $v_0 = 0$,

$$\Delta y = \tfrac{1}{2}g_{exp}(\Delta t)^2 \Rightarrow g_{exp} = \boxed{\frac{2\Delta y}{(\Delta t)^2}} \quad (1)$$

(*b*) Solve equation (1) for Δt to obtain:

$$\Delta t = \sqrt{\frac{2\Delta y}{g_{exp}}}$$

Substitute numerical values and evaluate Δt

$$\Delta t = \sqrt{\frac{2(1.00\text{ m})}{9.81\text{ m/s}^2}} = \boxed{0.452\text{ s}}$$

(*c*) Using a constant-acceleration equation, express the speed of the marble in terms of its initial speed, acceleration, and displacement:

$$v_f^2 = v_0^2 + 2a\Delta y$$

or, because $v_0 = 0$ and $a = g$,

$$v_f^2 = 2g\Delta y \Rightarrow v_f = \sqrt{2g\Delta y}$$

Let v_1 be the speed the ball has reached when it has fallen 0.50 cm, and v_2 be the speed the ball has reached when it has fallen 0.500 m to obtain.

$$v_1 = \sqrt{2(9.81\,\text{m/s}^2)(0.0050\,\text{m})}\ \text{and}$$
$$= 0.313\,\text{m/s}$$
$$v_2 = \sqrt{2(9.81\,\text{m/s}^2)(0.500\,\text{m})}$$
$$= 3.13\,\text{m/s}$$

Using a constant-acceleration equation, express v_2 in terms of v_1, g and Δt:

$$v_2 = v_1 + g\Delta t \Rightarrow \Delta t = \frac{v_2 - v_1}{g}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{3.13\,\text{m/s} - 0.313\,\text{m/s}}{9.81\,\text{m/s}^2} = 0.2872\,\text{s}$$

The distance the marble falls during this interval is:

$$\Delta y = 1.00\,\text{m} - 0.5000\,\text{m} - 0.0050\,\text{m}$$
$$= 0.50\,\text{m}$$

Use equation (1) to calculate the experimental value of the acceleration due to gravity:

$$g_{\text{exp}} = \frac{2(0.50\,\text{m})}{(0.2872\,\text{s})^2} = \boxed{12\,\text{m/s}^2}$$

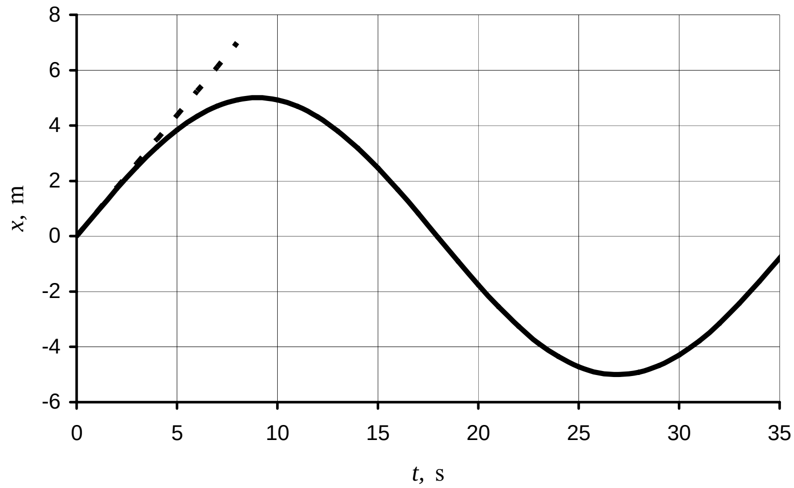
Finally, calculate the percent difference between this experimental result and the value accepted for g at sea level.

$$\%\ \text{difference} = \frac{\left|9.81\,\text{m/s}^2 - 12\,\text{m/s}^2\right|}{9.81\,\text{m/s}^2}$$
$$= \boxed{22\%}$$

114 ••• The position of a body oscillating on a spring is given by $x = A \sin \omega t$, where A and ω are constants, A = 5.0 cm. and $\omega = 0.175\ \text{s}^{-1}$. (*a*) Plot x as a function of t for $0 \le t \le 36$ s. (*b*) Measure the slope of your graph at $t = 0$ to find the velocity at this time. (*c*) Calculate the average velocity for a series of intervals, beginning at $t = 0$ and ending at t = 6.0, 3.0, 2.0, 1.0, 0.50, and 0.25 s. (*d*) Compute dx/dt to find the velocity at time $t = 0$. (*e*) Compare your results in Parts (*c*) and (*d*) and explain why your Part (*c*) results approach your Part (*d*) results.

Picture the Problem We can obtain an average velocity, $v_{\text{av}} = \Delta x/\Delta t$, over fixed time intervals. The instantaneous velocity, $v = dx/dt$ can only be obtained by differentiation.

(*a*) The following graph of *x* versus *t* was plotted using a spreadsheet program:



(*b*) Draw a tangent line at the origin and measure its rise and run. Use this ratio to obtain an approximate value for the slope at the origin:

The tangent line appears to, at least approximately, pass through the point (5, 4). Using the origin as the second point,

$$\Delta x = 4\text{ cm} - 0 = 4\text{ cm}$$

and

$$\Delta t = 5\text{ s} - 0 = 5\text{ s}$$

Therefore, the slope of the tangent line and the velocity of the body as it passes through the origin is approximately:

$$v(0) = \frac{\text{rise}}{\text{run}} = \frac{\Delta x}{\Delta t} = \frac{4\,\text{cm}}{5\,\text{s}} = \boxed{0.8\,\text{cm/s}}$$

(*c*) Calculate the average velocity for the series of time intervals given by completing the table shown below:

t_0	t	Δt	x_0	x	Δx	$v_{av}=\Delta x/\Delta t$
(s)	(s)	(s)	(cm)	(cm)	(cm)	(m/s)
0	6	6	0	4.34	4.34	0.723
0	3	3	0	2.51	2.51	0.835
0	2	2	0	1.71	1.71	0.857
0	1	1	0	0.871	0.871	0.871
0	0.5	0.5	0	0.437	0.437	0.874
0	0.25	0.25	0	0.219	0.219	0.875

(*d*) Express the time derivative of the position function:

$$\frac{dx}{dt} = A\omega\cos\omega t$$

Substitute numerical values and evaluate $\frac{dx}{dt}$ at $t = 0$:

$$\frac{dx}{dt} = A\omega\cos 0 = A\omega$$
$$= (0.050\text{ m})(0.175\text{ s}^{-1})$$
$$= \boxed{0.88\text{ cm/s}}$$

(*e*) Compare the average velocities from Part (*c*) with the instantaneous velocity from Part (*d*):

As Δt, and thus Δx, becomes small, the value for the average velocity approaches that for the instantaneous velocity obtained in Part (*d*). For $\Delta t = 0.25$ s, they agree to three significant figures.

115 ••• [SSM] Consider an object that is attached to a horizontally oscillating piston. The object moves with a velocity given by $v = B\sin(\omega t)$, where B and ω are constants and ω is in s^{-1}. (*a*) Explain why B is equal to the maximum speed v_{max}. (*b*) Determine the acceleration of the object as a function of time. Is the acceleration constant? (*c*) What is the maximum acceleration (magnitude) in terms of ω and v_{max}. (*d*) At $t = 0$, the object's position is known to be x_0. Determine the position as a function of time in terms of in terms of t, ω, x_0 and v_{max}.

Determine the Concept Because the velocity varies nonlinearly with time, the acceleration of the object is not constant. We can find the acceleration of the object by differentiating its velocity with respect to time and its position function by integrating the velocity function.

(*a*) The maximum value of the sine function (as in $v = v_{max}\sin(\omega t)$) is 1. Hence the coefficient B represents the maximum possible speed v_{max}.

(*b*) The acceleration of the object is the derivative of its velocity with respect to time:

$$a = \frac{dv}{dt} = \frac{d}{dt}[v_{max}\sin(\omega t)]$$
$$= \boxed{\omega v_{max}\cos(\omega t)}$$

Because *a* varies sinusoidally with time it is *not* constant.

(*c*) Examination of the coefficient of the cosine function in the expression for *a* leads one to the conclusion that $|a_{max}| = \boxed{\omega v_{max}\,.}$

(*d*) The position of the object as a function of time is the integral of the velocity function:

$$\int dx = \int v(t)\,dt$$

Integrating the left-hand side of the equation and substituting for v on the right-hand side yields:

$$x = \int v_{max}\sin(\omega t)dt + C$$

Integrate the right-hand side to obtain:

$$x = \frac{-v_{max}}{\omega}\cos(\omega t) + C \qquad (1)$$

Use the initial condition $x(0) = x_0$ to obtain:

$$x_0 = \frac{-v_{max}}{\omega} + C$$

Solving for C yields:

$$C = x_0 + \frac{v_{max}}{\omega}$$

Substitute for C in equation (1) to obtain:

$$x = \frac{-v_{max}}{\omega}\cos(\omega t) + x_0 + \frac{v_{max}}{\omega}$$

Solving this equation for x yields:

$$x = \boxed{x_0 + \frac{v_{max}}{\omega}[1 - \cos(\omega t)]}$$

116 ••• Suppose the acceleration of a particle is a function of x, where $a_x(x) = (2.0\text{ s}^{-2})x$. (*a*) If the velocity is zero when $x = 1.0$ m, what is the speed when $x = 3.0$ m? (*b*) How long does it take the particle to travel from $x = 1.0$ m to $x = 3.0$ m?

Picture the Problem Because the acceleration of the particle is a function of its position, it is not constant. Changing the variable of integration in the definition of acceleration will allow us to determine its velocity and position as functions of position.

(*a*) The acceleration of the particle is given by:

$$a = \frac{dv}{dt} = \frac{dv}{dx}\frac{dx}{dt} = v\frac{dv}{dx}$$

Separating variables yields:

$$vdv = adx$$

Substitute for a to obtain:

$$vdv = bxdx$$

where $b = 2.0\text{ s}^{-2}$

The limits of integration are $v_o = 0$ and v on the left-hand side and x_o and x on the right-hand:

$$\int_{v_0=0}^{v} vdv = \int_{x_0}^{x} bxdx$$

Integrating both sides of the equation yields:

$$v^2 - v_0^2 = b\left(x^2 - x_0^2\right)$$

Solve for v to obtain:

$$v = \sqrt{v_0^2 + b\left(x^2 - x_0^2\right)}$$

Now set $v_o = 0$, $x_o = 1.0$ m, $x = 3$ m, and $b = 2.0\ \text{s}^{-2}$ and evaluate the speed:

$$\left|v(3.0\ \text{m})\right| = \sqrt{\left(2.0\,\text{s}^{-2}\right)\left[(3.0\,\text{m})^2 - (1.0\,\text{m})^2\right]} = \boxed{4.0\ \text{m/s}}$$

(b) From the definition of instantaneous velocity we have:

$$t = \int_0^t dt = \int_{x_0}^{x} \frac{dx}{v(x)}$$

Substitute the expression for $v(x)$ derived in (a) to obtain:

$$t = \int_{x_0}^{x} \frac{dx}{\sqrt{b\left(x^2 - x_0^2\right)}}$$

Evaluate the integral using the formula found in standard integral tables to obtain:

$$t = \frac{1}{\sqrt{b}} \int_{x_0}^{x} \frac{dx}{\sqrt{x^2 - x_0^2}}$$

$$= \frac{1}{\sqrt{b}} \ln\left(\frac{x + \sqrt{x^2 - x_0^2}}{x_0}\right)$$

Substitute numerical values and evaluate t:

$$t = \frac{1}{\sqrt{2.0\,\text{s}^{-2}}} \ln\left(\frac{3.0\,\text{m} + \sqrt{(3.0\,\text{m})^2 - (1.0\,\text{m})^2}}{1.0\,\text{m}}\right) = \boxed{1.2\,\text{s}}$$

117 ••• [SSM] A rock falls through water with a continuously decreasing acceleration. Assume that the rock's acceleration as a function of *velocity* has the form $a_y = g - bv_y$ where b is a positive constant. (The $+y$ direction is directly downward.) (a) What are the SI units of b? (b) Prove mathematically that if the rock is released from rest at time $t = 0$, the acceleration will depend exponentially on *time* according to $a_y(t) = ge^{-bt}$. (c) What is the terminal speed for the rock in terms of g and b? (See Problem 38 for an explanation of the phenomenon of *terminal speed*.)

Picture the Problem Because the acceleration of the rock is a function of its velocity, it is not constant and we will have to integrate the acceleration function in order to find the velocity function. Choose a coordinate system in which downward is positive and the origin is at the point of release of the rock.

(a) All three terms in $a_y = g - bv_y$ must have the same units in order for the equation to be valid. Hence the units of bv_y must be acceleration units. Because the SI units of v_y are m/s, b must have units of $\boxed{\text{s}^{-1}.}$

(*b*) Rewrite $a_y = g - bv_y$ explicitly as a differential equation:

$$\frac{dv_y}{dt} = g - bv_y$$

Separate the variables, v_y on the left, t on the right:

$$\frac{dv_y}{g - bv_y} = dt$$

Integrate the left-hand side of this equation from 0 to v_y and the right-hand side from 0 to t:

$$\int_0^{v_y} \frac{dv_y}{g - bv_y} = \int_0^t dt$$

Integrating this equation yields:

$$-\frac{1}{b}\ln\left(\frac{g - bv_y}{g}\right) = t$$

Solve this expression for v_y to obtain:

$$v_y = \frac{g}{b}\left(1 - e^{-bt}\right) \qquad (1)$$

Differentiate this expression with respect to time to obtain an expression for the acceleration and complete the proof:

$$a_y = \frac{dv_y}{dt} = \frac{d}{dt}\left(\frac{g}{b}\left(1 - e^{-bt}\right)\right) = \boxed{ge^{-bt}}$$

(*c*) Take the limit, as $t \to \infty$, of both sides of equation (1):

$$\lim_{t\to\infty} v_y = \lim_{t\to\infty}\left[\frac{g}{b}\left(1 - e^{-bt}\right)\right]$$

and

$$v_t = \boxed{\frac{g}{b}}$$

Notice that this result depends only on *b* (inversely so). Thus *b* must include geometric factors like the shape and cross-sectional area of the falling object, as well as properties of the liquid such as density and temperature.

118 ••• A small rock sinking through water (see Problem 117) experiences an exponentially decreasing acceleration given by $a_y(t) = ge^{-bt}$, where *b* is a positive constant that depends on the shape and size of the rock and the physical properties of the water. Based upon this, find expressions for the velocity and position of the rock as functions of time. Assume that its initial position and velocity are both zero and that the $+y$ direction is directly downward.

Picture the Problem Because the acceleration of the rock is a function of time, it is not constant and we will have to integrate the acceleration function in order to find the velocity of the rock as a function of time. Similarly, we will have to integrate the velocity function in order to find the position of the rock as a function of time. Choose a coordinate system in which downward is positive and the origin at the point of release of the rock.

Separate variables in $a_y(t) = dv_y/dt = ge^{-bt}$ to obtain:

$$dv_y = ge^{-bt}dt$$

Integrating from $t_0 = 0$, $v_{0y} = 0$ to some later time t and velocity v_y yields:

$$v = \int_0^v dv = \int_0^t ge^{-bt}dt = \frac{g}{-b}\left[e^{-bt}\right]_0^t = \frac{g}{b}\left(1-e^{-bt}\right) = \boxed{v_\mathrm{t}\left(1-e^{-bt}\right)}$$

where $v_\mathrm{t} = \dfrac{g}{b}$

Separate variables in $v = \dfrac{dy}{dt} = v_\mathrm{t}\left(1-e^{-bt}\right)$ to obtain:

$$dy = v_\mathrm{t}\left(1-e^{-bt}\right)dt$$

Integrate from $t_\mathrm{o} = 0$, $y_\mathrm{o} = 0$ to some later time t and position y:

$$y = \int_0^y dy = \int_0^t v_\mathrm{t}\left(1-e^{-bt}\right)dt = v_\mathrm{term}\left[t + \frac{1}{b}e^{-bt}\right]_0^t = \boxed{v_\mathrm{t}t - \frac{v_\mathrm{t}}{b}\left(1-e^{-bt}\right)}$$

Remarks: This last result is very interesting. It says that throughout its free-fall, the object experiences drag; therefore it has not fallen as far at any given time as it would have if it were falling at the constant velocity, v_t.

119 ••• The acceleration of a skydiver jumping from an airplane is given by $a_y = g - bv_y^2$ where b is a positive constant depending on the skydiver's cross-sectional area and the density of the surrounding atmosphere she is diving through. The +y direction is directly downward. (a) If her initial speed is zero when stepping from a hovering helicopter, show that her speed as a function of time is given by $v_y(t) = v_\mathrm{t}\tanh(t/T)$ where v_t is the terminal speed (see Problem 38) given by $v_\mathrm{t} = \sqrt{g/b}$ and $T = v_\mathrm{t}/g$ is a time-scale parameter (b) What fraction of the terminal speed is the speed at $t = T$? (c) Use a **spreadsheet** program to graph $v_y(t)$ as a function of time, using a terminal speed of 56 m/s (use this value to calculate b and T). Does the resulting curve make sense?

Picture the Problem The skydiver's acceleration is a function of her speed; therefore it is not constant. Expressing her acceleration as the derivative of her speed, separating the variables, and then integrating will give her speed as a function of time.

(*a*) Rewrite $a_y = g - bv_y^2$ explicitly as a differential equation:

$$\frac{dv_y}{dt} = g - bv_y^2$$

Separate the variables, with v_y on the left, and t on the right:

$$\frac{dv_y}{g - bv_y^2} = dt$$

Eliminate b by using $b = \frac{g}{v_t^2}$:

$$\frac{dv_y}{g - \frac{g}{v_t^2}v_y^2} = \frac{dv_y}{g\left[1 - \left(\frac{v_y}{v_t}\right)^2\right]} = dt$$

or, separating variables,

$$\frac{dv_y}{1 - \left(\frac{v_y}{v_t}\right)^2} = gdt$$

Integrate the left-hand side of this equation from 0 to v_y and the right-hand side from 0 to t:

$$\int_0^{v_y} \frac{dv_y}{1 - \left(\frac{v_y}{v_t}\right)^2} = g\int_0^t dt = gt$$

The integral on the left-hand side can be found in integral tables:

$$v_t \tanh^{-1}\left(\frac{v_y}{v_t}\right) = gt$$

Solving this equation for v_y yields:

$$v_y = v_t \tanh\left(\frac{g}{v_t}\right)t$$

Because c has units of m^{-1}, and g has units of m/s^2, $(bg)^{-1/2}$ will have units of time. Let's represent this expression with the time-scale factor T:

$$T = (bg)^{-1/2}$$

The skydiver falls with her terminal speed when $a = 0$. Using this definition, relate her terminal speed to the acceleration due to gravity and the constant b in the acceleration equation:

$$0 = g - bv_t^2 \Rightarrow v_t = \sqrt{\frac{g}{b}}$$

Convince yourself that T is also equal to v_t/g and use this relationship to eliminate g and v_t in the solution to the differential equation:

$$v_y(t) = \boxed{v_t \tanh\left(\frac{t}{T}\right)}$$

(*b*) The ratio of the speed at any time to the terminal speed is given by:

$$\frac{v_y(t)}{v_t} = \frac{v_t \tanh\left(\frac{t}{T}\right)}{v_t} = \tanh\left(\frac{t}{T}\right)$$

Evaluate this ratio for $t = T$ to obtain:

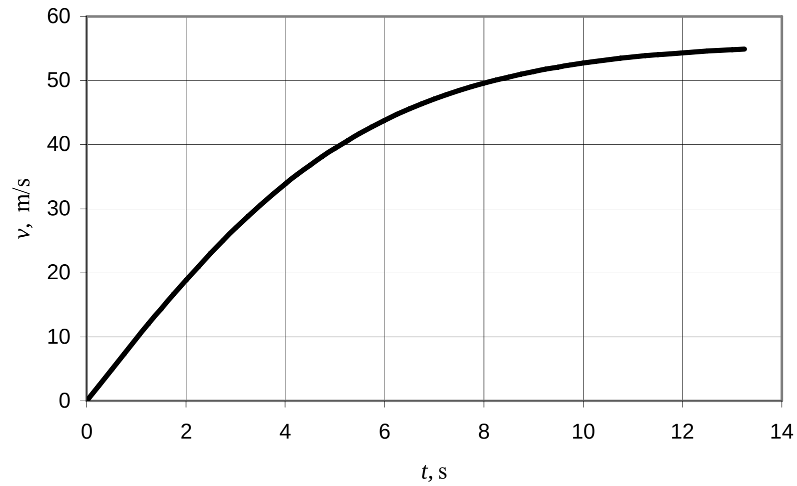
$$\frac{v_y(T)}{v_t} = \tanh\left(\frac{T}{T}\right) = \tanh(1) = \boxed{0.762}$$

(*c*) The following table was generated using a spreadsheet and the equation we derived in Part (*a*) for $v(t)$. The cell formulas and their algebraic forms are:

Cell	Content/Formula	Algebraic Form
D1	56	v_T
D2	5.71	T
B7	B6 + 0.25	$t + 0.25$
C7	$B$1*TANH(B7/$B$2)	$v_T \tanh\left(\frac{t}{T}\right)$

	A	B	C
1	v_T =	56	m/s
2	T=	5.71	s
3			
4			
5		t (s)	v (m/s)
6		0.00	0.00
7		0.25	2.45
8		0.50	4.89
9		0.75	7.32
56		12.50	54.61
57		12.75	54.73
58		13.00	54.83
59		13.25	54.93

A graph of v as a function of t follows:



Note that the speed increases linearly over time (that is, with constant acceleration) for about time T, but then it approaches the terminal speed as the acceleration decreases.

120 ••• Imagine that you are standing at a wishing well, wishing that you knew how deep the surface of the water was. Cleverly, you make your wish. Then, you take a penny from your pocket and drop it into the well. Exactly three seconds after you dropped the penny, you hear the sound it made when it struck the water. If the speed of sound is 343 m/s, how deep is the well? Neglect any effects due to air resistance.

Picture the Problem We know that the sound was heard exactly 3.00 s after the penny was dropped. This total time may be broken up into the time required for the penny to drop from your hand to the water's surface, and the time required for the sound to bounce back up to your ears. The time required for the penny to drop is related to the depth of the well. The use of a constant-acceleration equation in expressing the total fall time will lead to a quadratic equation one of whose roots will be the depth of the well

Express the time required for the sound to reach your ear as the sum of the drop time for the penny and the time for the sound to travel to your ear from the bottom of the well:

$$\Delta t_{\text{tot}} = \Delta t_{\text{drop}} + \Delta t_{\text{sound}} \qquad (1)$$

Use a constant-acceleration equation to express the depth of the well:

$$\Delta y_{\text{well}} = \tfrac{1}{2} g (\Delta t_{\text{drop}})^2 \Rightarrow \Delta t_{\text{drop}} = \sqrt{\frac{2\Delta y_{\text{well}}}{g}}$$

From the definition of average speed, the time Δt_{sound} required for the sound to travel from the bottom of the well to your ear is given by:

$$\Delta t_{\text{sound}} = \frac{\Delta y_{\text{well}}}{v_{\text{sound}}}$$

Substituting for Δt_{sound} and Δt_{drop} in equation (1) yields:

$$\Delta t_{\text{tot}} = \sqrt{\frac{2\Delta y_{\text{well}}}{g}} + \frac{\Delta y_{\text{well}}}{v_{\text{sound}}}$$

Isolate the radical term and square both sides of the equation to obtain:

$$\left(\Delta t_{\text{tot}} - \frac{\Delta y_{\text{well}}}{v_{\text{sound}}}\right)^2 = \frac{2\Delta y_{\text{well}}}{g}$$

Expanding the left side of this equation yields:

$$(\Delta t_{\text{tot}})^2 - 2\Delta t_{\text{tot}}\frac{\Delta y_{\text{well}}}{v_{\text{sound}}} + \left(\frac{\Delta y_{\text{well}}}{v_{\text{sound}}}\right)^2 = \frac{2\Delta y_{\text{well}}}{g}$$

Rewrite this equation explicitly as a quadratic equation in Δy_{well}:

$$\left(\frac{1}{v_{\text{sound}}}\right)^2 (\Delta y_{\text{well}})^2 - 2\left(\frac{1}{g} + \frac{\Delta t_{\text{tot}}}{v_{\text{sound}}}\right)\Delta y_{\text{well}} + (\Delta t_{\text{tot}})^2 = 0$$

Simplify further to obtain:

$$(\Delta y_{\text{well}})^2 - 2\left(\frac{v_{\text{sound}}^2}{g} + v_{\text{sound}}\Delta t_{\text{tot}}\right)\Delta y_{\text{well}} + (v_{\text{sound}}\Delta t_{\text{tot}})^2 = 0$$

Substituting numerical values yields:

$$(\Delta y_{\text{well}})^2 - 2\left(\frac{(343\text{ m/s})^2}{9.81\text{ m/s}^2} + (343\text{ m/s})(3.00\text{ s})\right)\Delta y_{\text{well}} + [(343\text{ m/s})(3.00\text{ s})]^2 = 0$$

or

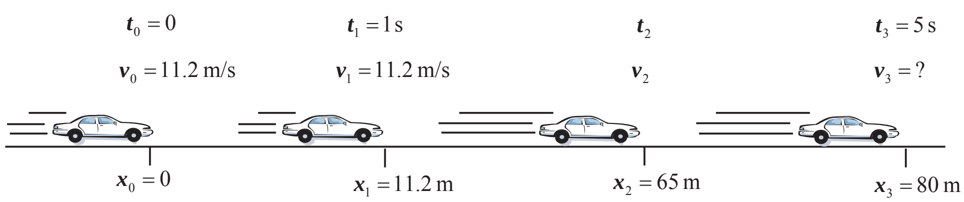
$$(\Delta y_{\text{well}})^2 - (2.604\times10^4\text{ m})\Delta y_{\text{well}} + 1.059\times10^6\text{ m}^2 = 0$$

Use the quadratic formula or your graphing calculator to solve for the smaller root of this equation (the larger root is approximately 26 km and is too large to be physically meaningful):

$$\Delta y_{\text{well}} = 40.73\text{ m} = \boxed{41\text{ m}}$$

121 ••• You are driving a car at the speed limit of 25-mi/h speed limit when you observe the light at the intersection 65 m in front of you turn yellow. You know that at that particular intersection the light remains yellow for exactly 5.0 s before turning red. After you think for 1.0 s, you then accelerate the car at a constant rate. You somehow manage to pass your 4.5-m-long car completely through the 15.0-m-wide intersection just as the light turns red, thus narrowly avoiding a ticket for being in an intersection when the light is red. Immediately after passing through the intersection, you take your foot off the accelerator, relieved. However, down the road, you are pulled over for speeding. You assume that you were ticketed for the speed of your car as it exited the intersection. Determine this speed and decide whether you should fight this ticket in court. Explain.

Picture the Problem First, we should find the total distance covered by the car between the time that the light turned yellow (and you began your acceleration) and the time that the back end of the car left the intersection. This distance is Δx_{tot} = 65.0 m + 15.0 m + 4.5 m = 84.5 m. Part of this distance, Δx_c is covered at constant speed, as you think about trying to make it through the intersection in time – this can be subtracted from the full distance Δx_{tot} above to yield Δx_{acc}, the displacement during the constant acceleration. With this information, we then can utilize a constant-acceleration equation to obtain an expression for your velocity as you exited the intersection. The following pictorial representation will help organize the information given in this problem.



Using a constant-acceleration equation relate the distance over which you accelerated to your initial velocity v_1, your acceleration a, and the time during which you accelerated a_{acc}:

$$\Delta x_{acc} = \Delta x_{tot} - \Delta x_c = v_1 \Delta t_{acc} + \tfrac{1}{2} a (\Delta t_{acc})^2$$

Relate the final velocity v_3 of the car to its velocity v_1 when it begins to accelerate, its acceleration, and the time during which it accelerates:

$$v_3 = v_1 + a\Delta t_{acc} \Rightarrow a = \frac{v_3 - v_1}{\Delta t_{acc}}$$

Substitute for a in the expression for Δx_{acc} to obtain:

$$\Delta x_{tot} - \Delta x_c = v_1 \Delta t_{acc} + \tfrac{1}{2}\left(\frac{v_3 - v_1}{\Delta t_{acc}}\right)(\Delta t_{acc})^2 = v_1 \Delta t_{acc} + \tfrac{1}{2}(v_3 - v_1)(\Delta t_{acc})$$

Solving for v_3 yields:

$$v_3 = \frac{2(\Delta x_{\text{tot}} - \Delta x_{\text{c}})}{\Delta t_{\text{acc}}} - v_1$$

Substitute numerical values and evaluate v_3:

$$v_3 = \frac{2(84.5\ \text{m} - 11.2\ \text{m})}{4.0\ \text{s}} - 11.2\ \text{m/s} = \boxed{25\ \text{m/s}}$$

Because 25 m/s is approximately 57 mi/h, you were approximately 32 mi/h over the speed limit! You would be foolish to contest your ticket.

122 ••• For a spherical celestial object of radius R, the acceleration due to gravity g at a distance x from the *center* of the object is $g = g_0 R^2/x^2$, where g_0 is the acceleration due to gravity at the object's surface and $x > R$. For the moon, take $g_0 = 1.63\ \text{m/s}^2$ and $R = 3200$ km. If a rock is released from rest at a height of $4R$ above the lunar surface, with what speed does the rock impact the moon? *Hint: Its acceleration is a function of position and increases as the object falls. So do not use constant acceleration free-fall equations, but go back to basics.*

Picture the Problem Let the origin be at the center of the moon and the $+x$ direction be radially outward. Because the acceleration of the rock is a function of its distance from the center of the moon, we'll need to change the variables of integration in the definition of acceleration to v and x in order to relate the rock's acceleration to its speed. Separating variables and integrating will yield an expression for the speed of the rock as a function of its distance from the center of the moon.

The acceleration of the object is given by:

$$a = \frac{dv}{dt} = \frac{dv}{dx}\frac{dx}{dt} = v\frac{dv}{dx}$$

Separating variables yields:

$$vdv = adx$$

Because $a = -g$:

$$vdv = -\frac{g_0 R^2}{x^2}dx$$

Expressing the integral of v from 0 to v and x from $4R$ to R yields:

$$\int_0^v vdv = \int_{4R}^{R} -\frac{g_0 R^2}{x^2}dx = -g_0 R^2 \int_{4R}^{R} \frac{dx}{x^2}$$

Carry out the integration to obtain:

$$\frac{v^2}{2} = g_0 R^2 \left[\left.\frac{1}{x}\right|_{4R}^{R}\right] = \frac{3}{4} g_0 R$$

Solve for v to obtain an expression for the speed of the object upon impact:

$$v = \sqrt{\frac{3}{2} g_0 R}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{3}{2}\left(1.63\ \text{m/s}^2\right)\left(1.738\times 10^6\ \text{m}\right)}$$

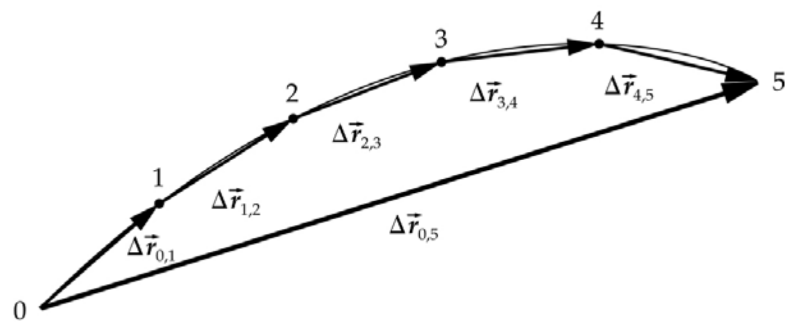
$$= \boxed{2.06\ \text{km/s}}$$

Chapter 3
Motion in Two and Three Dimensions

Conceptual Problems

1 • [SSM] Can the magnitude of the displacement of a particle be less than the distance traveled by the particle along its path? Can its magnitude be more than the distance traveled? Explain.

Determine the Concept The distance traveled along a path can be represented as a sequence of displacements.



Suppose we take a trip along some path and consider the trip as a sequence of many very small displacements. The net displacement is the vector sum of the very small displacements, and the total distance traveled is the sum of the magnitudes of the very small displacements. That is,

$$\textit{total distance} = \left|\Delta\vec{r}_{0,1}\right| + \left|\Delta\vec{r}_{1,2}\right| + \left|\Delta\vec{r}_{2,3}\right| + \ldots + \left|\Delta\vec{r}_{N-1,N}\right|$$

where N is the number of very small displacements. (For this to be exactly true we have to take the limit as N goes to infinity and each displacement magnitude goes to zero.) Now, using ″the shortest distance between two points is a straight line,″ we have

$$\left|\Delta\vec{r}_{0,N}\right| \le \left|\Delta\vec{r}_{0,1}\right| + \left|\Delta\vec{r}_{1,2}\right| + \left|\Delta\vec{r}_{2,3}\right| + \ldots + \left|\Delta\vec{r}_{N-1,N}\right|,$$

where $\left|\Delta\vec{r}_{0,N}\right|$ is the magnitude of the net displacement.

Hence, we have shown that the magnitude of the displacement of a particle is less than or equal to the distance it travels along its path.

2 • Give an example in which the distance traveled is a significant amount, yet the corresponding displacement is zero. Can the reverse be true? If so, give an example.

Determine the Concept The displacement of an object is its final position vector minus its initial position vector ($\Delta\vec{r} = \vec{r}_f - \vec{r}_i$). The displacement can be less but never more than the distance traveled. Suppose the path is one complete trip around Earth at the equator. Then, the displacement is 0 but the distance traveled is $2\pi R_e$. No, the reverse cannot be true.

3 • What is the average velocity of a batter who hits a home run (from when he hits the ball to when he touches home plate after rounding the bases)?

Determine the Concept The important distinction here is that ***average velocity*** is being requested, as opposed to ***average speed***.

The average velocity is defined as the displacement divided by the elapsed time.

$$\vec{v}_{av} = \frac{\Delta\vec{r}}{\Delta t} = \frac{0}{\Delta t} = 0$$

The displacement for any trip around the bases is zero. Thus we see that no matter how fast the runner travels, the average velocity is always zero at the end of each complete circuit of the bases.

What is the correct answer if we were asked for *average speed*?

The average speed is defined as the distance traveled divided by the elapsed time.

$$v_{av} = \frac{\text{total distance}}{\Delta t}$$

For one complete circuit of any track, the total distance traveled will be greater than zero and so the average speed is not zero.

4 • A baseball is hit so its initial velocity upon leaving the bat makes an angle of 30° above the horizontal. It leaves that bat at a height of 1.0 m above the ground and lands untouched for a single. During its flight, from just after it leaves the bat to just before it hits the ground, describe how the angle between its velocity and acceleration vectors changes. Neglect any effects due to air resistance.

Determine the Concept The angle between its velocity and acceleration vectors starts at 30° + 90° or 120° because the acceleration of the ball is straight down. At the peak of the flight of the ball the angle reduces to 90° because the ball's velocity vector is horizontal. When the ball reaches the same elevation that it started from the angle is 90° − 30° or 60°.

5 • If an object is moving toward the west at some instant, in what direction is its acceleration? (*a*) north, (*b*) east, (*c*) west, (*d*) south, (*e*) may be any direction.

Determine the Concept The *instantaneous acceleration* is the limiting value, as Δt approaches zero, of $\Delta\vec{v}/\Delta t$ and is in the same direction as $\Delta\vec{v}$.

Other than through the definition of $\vec{a}$, the instantaneous velocity and acceleration vectors are unrelated. Knowing the direction of the velocity at one instant tells one nothing about how the velocity is changing at that instant. $\boxed{(e)}$ is correct.

6 • Two astronauts are working on the lunar surface to install a new telescope. The acceleration due to gravity on the Moon is only 1.64 m/s^2. One astronaut tosses a wrench to the other astronaut but the speed of throw is excessive and the wrench goes over her colleague's head. When the wrench is at the highest point of its trajectory (*a*) its velocity and acceleration are both zero, (*b*) its velocity is zero but its acceleration is nonzero, (*c*) its velocity is nonzero but its acceleration is zero, (*d*) its velocity and acceleration are both nonzero, (*e*) insufficient information is given to choose between any of the previous choices.

Determine the Concept When the wrench reaches its maximum height, it is still moving horizontally but its acceleration is downward. $\boxed{(d)}$ is correct.

7 • The velocity of a particle is directed toward the east while the acceleration is directed toward the northwest as shown in Figure 3-27. The particle is (*a*) speeding up and turning toward the north, (*b*) speeding up and turning toward the south, (*c*) slowing down and turning toward the north, (*d*) slowing down and turning toward the south, (*e*) maintaining constant speed and turning toward the south.

Determine the Concept The change in the velocity is in the same direction as the acceleration. Choose an *x*-*y* coordinate system with east being the positive *x* direction and north the positive *y* direction. Given our choice of coordinate system, the *x* component of $\vec{a}$ is negative and so $\vec{v}$ will decrease. The *y* component of $\vec{a}$ is positive and so $\vec{v}$ will increase toward the north. $\boxed{(c)}$ is correct.

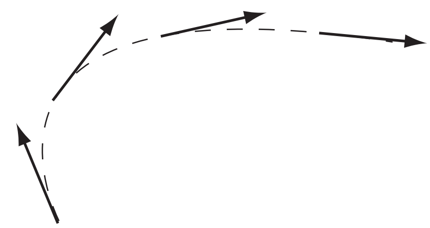
8 • Assume you know the position vectors of a particle at two points on its path, one earlier and one later. You also know the time it took the particle to move from one point to the other. Then you can then compute the particle's (*a*) average velocity, (*b*) average acceleration, (*c*) instantaneous velocity, (*d*) instantaneous acceleration.

Determine the Concept All you can compute is the average velocity, since no instantaneous quantities can be computed and you need two instantaneous velocities to compute the average acceleration. $\boxed{(a)}$ is correct.

9 • Consider the path of a moving particle. (*a*) How is the velocity vector related geometrically to the path of the particle? (*b*) Sketch a curved path and draw the velocity vector for the particle for several positions along the path.

Determine the Concept (*a*) The velocity vector, as a consequence of always being in the direction of motion, is tangent to the path.

(*b*) A sketch showing two velocity vectors for a particle moving along a curved path is shown to the right.



10 • The acceleration of a car is zero when it is (*a*) turning right at a constant speed, (*b*) driving up a long straight incline at constant speed, (*c*) traveling over the crest of a hill at constant speed, (*d*) bottoming out at the lowest point of a valley at constant speed, (*e*) speeding up as it descends a long straight decline.

Determine the Concept An object experiences acceleration whenever either its speed changes or it changes direction.

The acceleration of a car moving in a straight path at constant speed is zero. In the other examples, either the magnitude or the direction of the velocity vector is changing and, hence, the car is accelerated. $\boxed{(b)}$ is correct.

11 • **[SSM]** Give examples of motion in which the directions of the velocity and acceleration vectors are (*a*) opposite, (*b*) the same, and (*c*) mutually perpendicular.

Determine the Concept The velocity vector is defined by $\vec{v} = d\vec{r}/dt$, while the acceleration vector is defined by $\vec{a} = d\vec{v}/dt$.

(*a*) A car moving along a straight road while braking.

(*b*) A car moving along a straight road while speeding up.

(*c*) A particle moving around a circular track at constant speed.

12 • How is it possible for a particle moving at constant speed to be accelerating? Can a particle with constant velocity be accelerating at the same time?

Determine the Concept A particle experiences accelerated motion when either its speed or direction of motion changes.

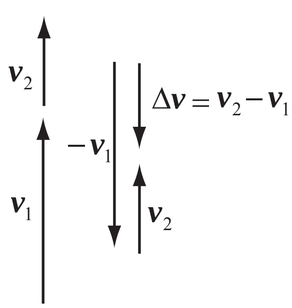
A particle moving at constant speed in a circular path is accelerating because the direction of its velocity vector is changing.

If a particle is moving at constant velocity, it is not accelerating.

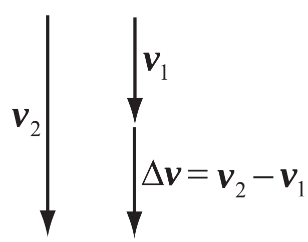
13 • **[SSM]** Imagine throwing a dart straight upward so that it sticks into the ceiling. After it leaves your hand, it steadily slows down as it rises before it sticks. (*a*) Draw the dart's velocity vector at times t_1 and t_2, where t_1 and t_2 occur after it leaves your hand but before it impacts the ceiling, and $\Delta t = t_2 - t_1$ is small. From your drawing find the direction of the change in velocity $\Delta\vec{v} = \vec{v}_2 - \vec{v}_1$, and thus the direction of the acceleration vector. (*b*) After it has stuck in the ceiling for a few seconds, the dart falls down to the floor. As it falls it speeds up, of course, until it hits the floor. Repeat Part (*a*) to find the direction of its acceleration vector as it falls. (*c*) Now imagine tossing the dart horizontally. What is the direction of its acceleration vector after it leaves your hand, but before it strikes the floor?

Determine the Concept The acceleration vector is in the same direction as the *change in velocity vector,* $\Delta\vec{v}$.

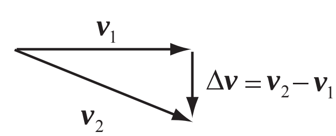
(*a*) The sketch for the dart thrown upward is shown below. The acceleration vector is in the direction of the *change* in the velocity vector $\Delta\vec{v}$.



(*b*) The sketch for the falling dart is shown below. Again, the acceleration vector is in the direction of the *change* in the velocity vector $\Delta\vec{v}$.



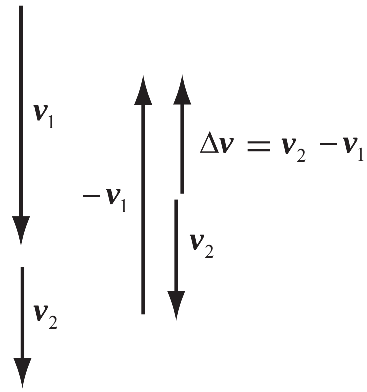
(*c*) The acceleration vector is in the direction of the *change* in the velocity vector … and hence is downward as shown below:



14 • As a bungee jumper approaches the lowest point in her descent, the rubber cord holding her stretches and she loses speed as she continues to move downward. Assuming that she is dropping straight down, make a motion diagram to find the direction of her acceleration vector as she slows down by drawing her velocity vectors at times t_1 and t_2, where t_1 and t_2 are two instants during the portion of her descent that she is losing speed and $t_2 - t_1$ is small. From your

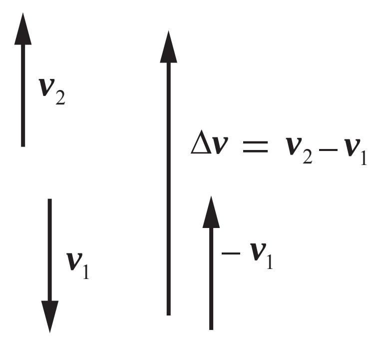
drawing find the direction of the change in velocity $\Delta\vec{v} = \vec{v}_2 - \vec{v}_1$, and thus the direction of the acceleration vector.

Determine the Concept The acceleration vector is in the same direction as the *change in velocity vector*, $\Delta\vec{v}$. The drawing is shown to the right.



15 • After reaching the lowest point in her jump at time t_{low}, a bungee jumper moves upward, gaining speed for a short time until gravity again dominates her motion. Draw her velocity vectors at times t_1 and t_2, where $\Delta t = t_2 - t_1$ is small and $t_1 < t_{low} < t_2$. From your drawing find the direction of the change in velocity $\Delta\vec{v} = \vec{v}_2 - \vec{v}_1$, and thus the direction of the acceleration vector at time t_{low}.

Determine the Concept The acceleration vector is in the same direction as the *change in the velocity vector,* $\Delta\vec{v}$. The drawing is shown to the right.



16 • A river is 0.76 km wide. The banks are straight and parallel (Figure 3-28). The current is 4.0 km/h and is parallel to the banks. A boat has a maximum speed of 4.0 km/h in still water. The pilot of the boat wishes to go on a straight line from A to B, where the line AB is perpendicular to the banks. The pilot should (*a*) head directly across the river, (*b*) head 53° upstream from the line AB, (*c*) head 37° upstream from the line AB, (*d*) give up—the trip from A to B is not possible with a boat of this limited speed, (*e*) do none of the above.

Determine the Concept We can decide what the pilot should do by considering the speeds of the boat and of the current. The speed of the stream is equal to the maximum speed of the boat in still water. The best the boat can do is, while facing directly upstream, maintain its position relative to the bank. So, the pilot should give up. $\boxed{(d)}$ is correct.

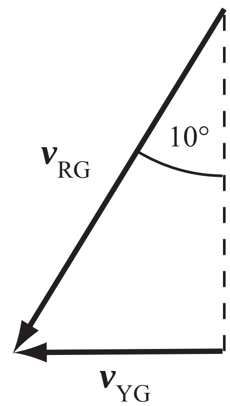
17 • **[SSM]** During a heavy rain, the drops are falling at a constant velocity and at an angle of 10° west of the vertical. You are walking in the rain and notice that only the top surfaces of your clothes are getting wet. In what direction are you walking? Explain.

Determine the Concept You must be walking west to make it appear to you that the rain is exactly vertical.

18 • In Problem 17, what is your walking speed if the speed of the drops relative to the ground is 5.2 m/s?

Determine the Concept Let $\vec{v}_{YG}$ represent your velocity relative to the ground and $\vec{v}_{RG}$ represent the velocity of the rain relative to the ground. Then your speed relative to the ground is given by

$$v_{YG} = (5.2\text{ m/s})\sin 10° = \boxed{0.90\text{ m/s}}$$



19 • True or false (Ignore any effects due to air resistance):

(*a*) When a projectile is fired horizontally, it takes the same amount of time to reach the ground as an identical projectile dropped from rest from the same height.
(*b*) When a projectile is fired from a certain height at an upward angle, it takes longer to reach the ground than does an identical projectile dropped from rest from the same height.
(*c*) When a projectile is fired horizontally from a certain height, it has a higher speed upon reaching the ground than does an identical projectile dropped from rest from the same height.

(*a*) True. In the absence of air resistance, both projectiles experience the same downward acceleration. Because both projectiles have initial vertical velocities of zero, their vertical motions must be identical.

(*b*) True. When a projectile is fired from a certain height at an upward angle, its time in the air is larger because it first rises to a greater height before beginning to fall with zero initial vertical velocity.

(*c*) True. When a projectile is fired horizontally, its velocity upon reaching the ground has a horizontal component in addition to the vertical component it has when it is dropped from rest. The magnitude of this velocity is related to its horizontal and vertical components through the Pythagorean Theorem.

20 • A projectile is fired at 35º above the horizontal. Any effects due to air resistance are negligible. At the highest point in its trajectory, its speed is 20 m/s. The initial velocity had a horizontal component of (*a*) 0, (*b*) (20 m/s) cos 35º, (*c*) (20 m/s) sin 35º, (*d*) (20 m/s)/cos 35º, (*e*) 20 m/s.

Determine the Concept In the absence of air resistance, the horizontal component of the projectile's velocity is constant for the duration of its flight. At the highest point, the speed is the horizontal component of the initial velocity. The vertical component is zero at the highest point. $\boxed{(e)}$ is correct.

21 • **[SSM]** A projectile is fired at 35º above the horizontal. Any effects due to air resistance are negligible. The initial velocity of the projectile in Problem 20 has a vertical component that is (*a*) less than 20 m/s, (*b*) greater than 20 m/s, (*c*) equal to 20 m/s, (*d*) cannot be determined from the data given.

Determine the Concept $\boxed{(a)}$ is correct. Because the initial horizontal velocity is 20 m/s and the launch angle is less than 45 degrees, the initial vertical velocity must be less than 20 m/s.

22 • A projectile is fired at 35º above the horizontal. Any effects due to air resistance are negligible. The projectile lands at the same elevation of launch, so the vertical component of the impact velocity is (*a*) the same as the vertical component of its initial velocity in both magnitude and direction, (*b*) the same as the vertical component of its initial velocity, (*c*) less than the vertical component of its initial velocity, (*d*) less than the vertical component of its initial velocity.

Determine the Concept $\boxed{(b)}$ is correct. The landing speed is the same as the launch speed. Because the horizontal component of its initial velocity does not change, the vertical component of the velocity at landing must be the same magnitude but oppositely directed its vertical component at launch.

23 • Figure 3-29 represents the trajectory of a projectile going from A to E. Air resistance is negligible. What is the direction of the acceleration at point B? (*a*) up and to the right, (*b*) down and to the left, (*c*) straight up, (*d*) straight down, (*e*) The acceleration of the ball is zero.

Determine the Concept $\boxed{(d)}$ is correct. In the absence of air resistance, the acceleration of the ball depends only on the *change in its velocity* and is independent of its velocity. As the ball moves along its trajectory between points A and C, the vertical component of its velocity decreases and the *change* in its velocity is a downward pointing vector. Between points C and E, the vertical component of its velocity increases and the *change* in its velocity is also a downward pointing vector. There is no change in the horizontal component of the velocity.

24 • Figure 3-29 represents the trajectory of a projectile going from A to E. Air resistance is negligible. (*a*) At which point(s) is the speed the greatest? (*b*) At which point(s) is the speed the least? (*c*) At which two points is the speed the same? Is the velocity also the same at these points?

Determine the Concept In the absence of air resistance, the horizontal component of the velocity remains constant throughout the flight. The vertical component has its maximum values at launch and impact.

(*a*) The speed is greatest at A and E.

(*b*) The speed is least at point C.

(*c*) The speed is the same at A and E. No. The horizontal components are equal at these points but the vertical components are oppositely directed, so the velocity is not the same at A and E.

25 • **[SSM]** True or false:

(*a*) If an object's speed is constant, then its acceleration must be zero.
(*b*) If an object's acceleration is zero, then its speed must be constant.
(*c*) If an object's acceleration is zero, its velocity must be constant.
(*d*) If an object's speed is constant, then its velocity must be constant.
(*e*) If an object's velocity is constant, then its speed must be constant.

Determine the Concept Speed is a scalar quantity, whereas acceleration, equal to the *rate of change* of velocity, is a vector quantity.

(*a*) False. Consider a ball moving in a horizontal circle on the end of a string. The ball can move with constant *speed* (a scalar) even though its *acceleration* (a vector) is always changing direction.

(*b*) True. From its definition, if the acceleration is zero, the velocity must be constant and so, therefore, must be the speed.

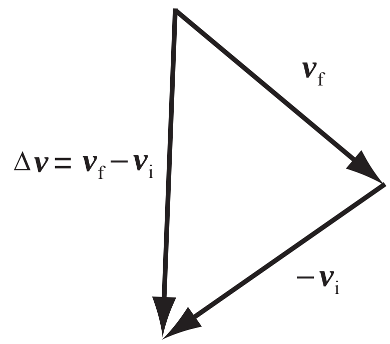
(*c*) True. An object’s velocity must change in order for the object to have acceleration other than zero.

(*d*) False. Consider an object moving at constant speed along a circular path. Its velocity changes continuously along such a path.

(*e*) True. If the velocity of an object is constant, then both its direction and magnitude (speed) must be constant.

26 • The initial and final velocities of a particle are as shown in Figure 3-30. Find the direction of the average acceleration.

Determine the Concept The average acceleration vector is defined by $\vec{a}_{av} = \Delta\vec{v}/\Delta t$. The direction of $\vec{a}_{av}$ is that of $\Delta\vec{v} = \vec{v}_f - \vec{v}_i$, as shown to the right.



27 •• The automobile path shown in Figure 3-31 is made up of straight lines and arcs of circles. The automobile starts from rest at point A. After it reaches point B, it travels at constant speed until it reaches point E. It comes to rest at point F. (*a*) At the middle of each segment (AB, BC, CD, DE, and EF), what is the direction of the velocity vector? (*b*) At which of these points does the automobile have a nonzero acceleration? In those cases, what is the direction of the acceleration? (*c*) How do the magnitudes of the acceleration compare for segments BC and DE?

Determine the Concept The velocity vector is in the same direction as *the change in the position vector* while the acceleration vector is in the same direction as *the change in the velocity vector*. Choose a coordinate system in which the y direction is north and the x direction is east.

(*a*)

Path	Direction of velocity vector
AB	north
BC	northeast
CD	east
DE	southeast
EF	south

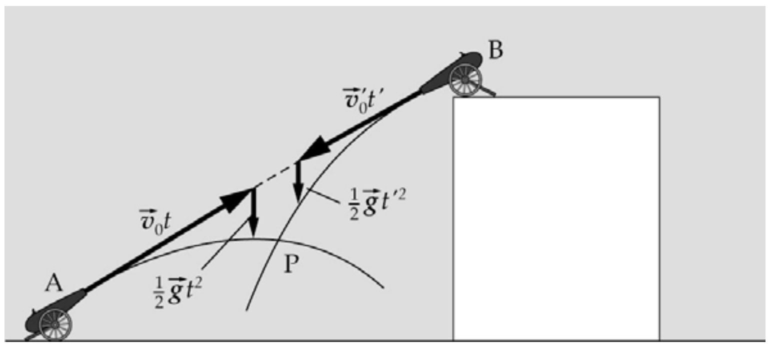
(*b*)

Path	Direction of acceleration vector
AB	north
BC	southeast
CD	0
DE	southwest
EF	north

(*c*) The magnitudes are comparable, but larger for DE because the radius of the path is smaller there.

28 •• Two cannons are pointed directly toward each other as shown in Figure 3-32. When fired, the cannonballs will follow the trajectories shown—P is the point where the trajectories cross each other. If we want the cannonballs to hit each other, should the gun crews fire cannon A first, cannon B first, or should they fire simultaneously? Ignore any effects due to air resistance.

Determine the Concept We'll assume that the cannons are identical and use a constant-acceleration equation to express the displacement of each cannonball as a function of time. Having done so, we can then establish the condition under which they will have the same vertical position at a given time and, hence, collide. The modified diagram shown below shows the displacements of both cannonballs.



Express the displacement of the cannonball from cannon A at any time t after being fired and before any collision:

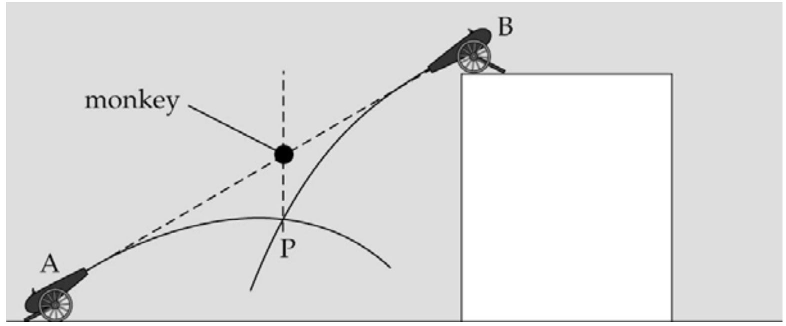
$$\Delta\vec{r} = \vec{v}_0t + \tfrac{1}{2}\vec{g}t^2$$

Express the displacement of the cannonball from cannon A at any time t' after being fired and before any collision:

$$\Delta\vec{r}\,' = \vec{v}_0't' + \tfrac{1}{2}\vec{g}t'^2$$

If the guns are fired simultaneously, $t = t'$ and the balls are the same distance $\frac{1}{2}gt^2$ below the line of sight at all times. Also, because the cannons are identical, the cannonballs have the same horizontal component of velocity and will reach the horizontal midpoint at the same time. Therefore, they should fire the guns simultaneously.

Remarks: This is the ″monkey and hunter″ problem in disguise. If you imagine a monkey in the position shown below, and the two guns are fired simultaneously, and the monkey begins to fall when the guns are fired, then the monkey and the two cannonballs will all reach point P at the same time.

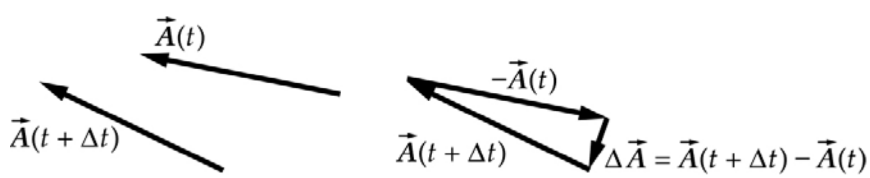


29 •• Galileo wrote the following in his ***Dialogue concerning the two world systems****:* "Shut yourself up . . . in the main cabin below decks on some large ship, and . . . hang up a bottle that empties drop by drop into a wide vessel beneath it. When you have observed [this] carefully . . . have the ship proceed with any speed you like, so long as the motion is uniform and not fluctuating this way and that. The droplets will fall as before into the vessel beneath without dropping towards the stern, although while the drops are in the air the ship runs many spans." Explain this quotation.

Determine the Concept The droplet leaving the bottle has the same horizontal velocity as the ship. During the time the droplet is in the air, it is also moving horizontally with the same velocity as the rest of the ship. Because of this, it falls into the vessel, which has the same horizontal velocity. Because you have the same horizontal velocity as the ship does, you see the same thing as if the ship were standing still.

30 • A man swings a stone attached to a rope in a horizontal circle at constant speed. Figure 3-33 represents the path of the rock looking down from above. (*a*) Which of the vectors could represent the velocity of the stone? (*b*) Which could represent the acceleration?

Determine the Concept (*a*) Because $\vec{A}$ and $\vec{D}$ are tangent to the path of the stone, either of them could represent the velocity of the stone.



(*b*) Let the vectors $\vec{A}(t)$ and $\vec{A}(t+\Delta t)$ be of equal length but point in slightly different directions as the stone moves around the circle. These two vectors and $\Delta\vec{A}$ are shown in the diagram above. Note that $\Delta\vec{A}$ is nearly perpendicular to $\vec{A}(t)$. For very small time intervals, $\Delta\vec{A}$ and $\vec{A}(t)$ are perpendicular to one another. Therefore, $d\vec{A}/dt$ is perpendicular to $\vec{A}$ and only the vector $\vec{E}$ could represent the acceleration of the stone.

31 •• True or false:

(*a*) An object cannot move in a circle unless it has centripetal acceleration.
(*b*) An object cannot move in a circle unless it has tangential acceleration.
(*c*) An object moving in a circle cannot have a variable speed.
(*d*) An object moving in a circle cannot have a constant velocity.

(*a*) True. An object accelerates when its velocity changes; that is, when either its speed or its direction changes. When an object moves in a circle the direction of its motion is continually changing.

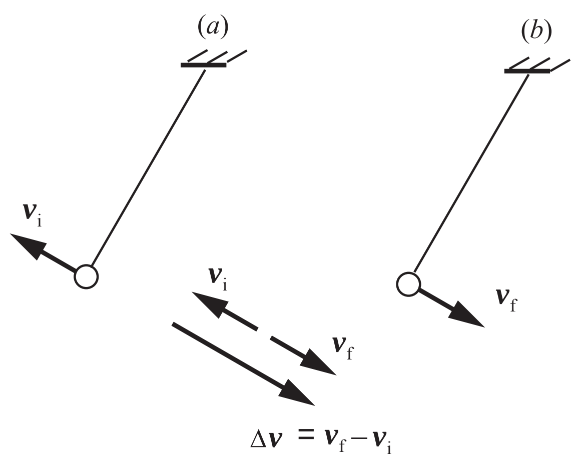
(*b*) False. An object moving in a circular path at constant speed has a tangential acceleration of zero.

(*c*) False. A good example is a rock wedged in the tread of an automobile tire. Its speed changes whenever the car's speed changes.

(*d*) True. The velocity vector of any object moving in a circle is continually changing direction.

32 •• Using a motion diagram, find the direction of the acceleration of the bob of a pendulum when the bob is at a point where it is just reversing its direction.

Picture the Problem In the diagram, (*a*) shows the pendulum just before it reverses direction and (*b*) shows the pendulum just after it has reversed its direction. The acceleration of the bob is in the direction of the *change* in the velocity $\Delta\vec{v} = \vec{v}_{\mathrm{f}} - \vec{v}_{\mathrm{i}}$ and is tangent to the pendulum trajectory at the point of reversal of direction. This makes sense because, at an extremum of motion, $v = 0$, so there is no centripetal acceleration. However, because the velocity is reversing direction, the tangential acceleration is nonzero.

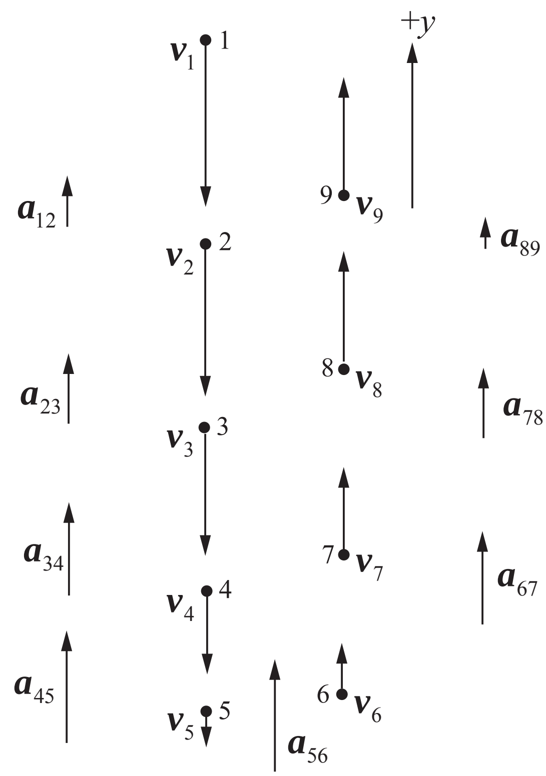


33 •• **[SSM]** During your rookie bungee jump, your friend records your fall using a camcorder. By analyzing it frame by frame, he finds that the *y*-component of your velocity is (recorded every 1/20th of a second) as follows:

t (s)	12.05	12.10	12.15	12.20	12.25	12.30	12.35	12.40	12.45
v_y (m/s)	–0.78	–0.69	–0.55	–0.35	–0.10	0.15	0.35	0.49	0.53

(*a*) Draw a motion diagram. Use it to find the direction and relative magnitude of your average acceleration for each of the eight successive 0.050 s time intervals in the table. (*b*) Comment on how the *y* component of your acceleration does or does not vary in sign and magnitude as you reverse your direction of motion.

Determine the Concept (*a*) The motion diagram shown below was constructed using the data in the table shown below the motion diagram. The column for Δv in the table was calculated using $\Delta v = v_i - v_{i-1}$ and the column for a was calculated using $a = (v_i - v_{i-1})/\Delta t$.



i	v	Δv	a_{ave}
	(m/s)	(m/s)	(m/s^2)
1	–0.78		
2	–0.69	0.09	1.8
3	–0.55	0.14	2.8
4	–0.35	0.20	4.0
5	–0.10	0.25	5.0
6	0.15	0.25	5.0

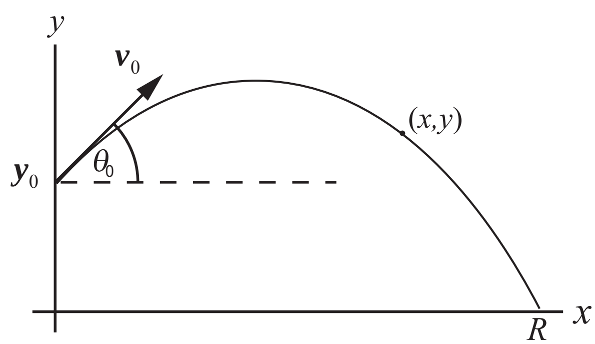
7	0.35	0.20	4.0
8	0.49	0.14	2.8
9	0.53	0.04	0.8

(*b*) The acceleration vector always points upward and so the sign of its *y* component does not change. The magnitude of the acceleration vector is greatest when the bungee cord has its maximum extension (your speed, the magnitude of your velocity, is least at this time and times near it) and is less than this maximum value when the bungee cord has less extension.

Estimation and Approximation

34 •• Estimate the speed in mph with which water comes out of a garden hose using your past observations of water coming out of garden hoses and your knowledge of projectile motion.

Picture the Problem Based on your experience with garden hoses, you probably know that the maximum range of the water is achieved when the hose is inclined at about 45° with the vertical. A reasonable estimate of the range of such a stream is about 4.0 m when the initial height of the stream is 1.0 m. Use constant-acceleration equations to obtain expressions for the *x* and *y* coordinates of a droplet of water in the stream and then eliminate time between these equations to obtain an equation that you can solve for v_0.



Use constant-acceleration equations to express the *x* and *y* components of a molecule of water in the stream:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$
and
$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

Because $x_0 = 0$, $x = R$, $a_y = -g$, and $a_x = 0$:

$$x = v_{0x}t \qquad (1)$$
and
$$y = y_0 + v_{0y}t - \tfrac{1}{2}gt^2 \qquad (2)$$

Express v_{0x} and v_{0y} in terms of v_0 and θ:

$v_{0x} = v_0 \cos\theta_0$ and $v_{0y} = v_0 \sin\theta_0$

where θ_0 is the angle the stream makes with the horizontal.

Substitute in equations (1) and (2) to obtain:

$$x = (v_0 \cos\theta_0)t \qquad (3)$$

and

$$y = y_0 + (v_0 \sin\theta_0)t - \tfrac{1}{2}gt^2 \qquad (4)$$

Eliminating t from equations (3) and (4) yields:

$$y = y_0 + (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2$$

When the stream of water hits the ground, $y = 0$ and $x = R$:

$$0 = y_0 + (\tan\theta_0)R - \frac{g}{2v_0^2\cos^2\theta_0}R^2$$

Solving this equation for v_0 gives:

$$v_0 = R\sqrt{\frac{g}{2\cos^2\theta\left[R\tan\theta + y_0\right]}}$$

Substitute numerical values and evaluate v_0:

$$v_0 = (4.0\text{ m})\sqrt{\frac{9.81\text{ m/s}^2}{2\cos^2 45°\left[(4.0\text{ m})\tan 45° + 1.0\text{ m}\right]}} = 5.603\text{ m/s}$$

Use a conversion factor, found in Appendix A, to convert m/s to mi/h:

$$v_0 = 5.603\text{ m/s} \times \frac{1\text{ mi/h}}{0.4470\text{ m/s}} \approx \boxed{13\text{ mi/h}}$$

35 •• [SSM] You won a contest to spend a day with all team during their spring training camp. You are allowed to try to hit some balls thrown by a pitcher. Estimate the acceleration during the hit of a fastball thrown by a major league pitcher when you hit the ball squarely-straight back at the pitcher. You will need to make reasonable choices for ball speeds, both just before and just after the ball is hit, and of the contact time the ball has with the bat.

Determine the Concept The magnitude of the acceleration of the ball is given by $a = |\vec{a}| = \left|\frac{\Delta\vec{v}}{\Delta t}\right|$. Let $\vec{v}_{\text{after}}$ represent the velocity of the ball just after its collision with the bat and $\vec{v}_{\text{before}}$ its velocity just before this collision. Most major league pitchers can throw a fastball at least 90 mi/h and some occasionally throw as fast as 100 mi/h. Let's assume that the pitcher throws you an 80 mph fastball.

The magnitude of the acceleration of the ball is:

$$a=\left|\frac{\vec{v}_{\text{after}}-\vec{v}_{\text{before}}}{\Delta t}\right|.$$

Assuming that v_{after} and v_{before} are both 80 mi/h and that the ball is in contact with the bat for 1 ms:

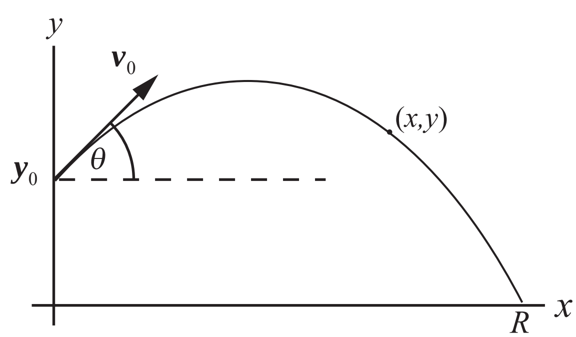
$$a=\frac{80\ \text{mi/h}-(-80\ \text{mi/h})}{1\ \text{ms}}=\frac{160\ \text{mi/h}}{1\ \text{ms}}$$

Converting a to m/s^2 yields:

$$a=\frac{160\ \text{mi/h}}{1\ \text{ms}}\times\frac{0.447\ \text{m/s}}{1\ \text{mi/h}}\approx\boxed{7\times10^4\ \text{m/s}^2}$$

36 •• Estimate how far you can throw a ball if you throw it (*a*) horizontally while standing on level ground, (*b*) at $\theta = 45°$ above horizontal while standing on level ground, (*c*) horizontally from the top of a building 12 m high, (*d*) at $\theta = 45°$ above horizontal from the top of a building 12 m high. Ignore any effects due to air resistance.

Picture the Problem During the flight of the ball the acceleration is constant and equal to 9.81 m/s^2 directed downward. We can find the flight time from the vertical part of the motion, and then use the horizontal part of the motion to find the horizontal distance. We'll assume that the release point of the ball is 2.0 m above your feet. A sketch of the motion that includes coordinate axes, the initial and final positions of the ball, the launch angle, and the initial velocity follows.



Obviously, how far you throw the ball will depend on how fast you can throw it. A major league baseball pitcher can throw a fastball at 90 mi/h or so. Assume that you can throw a ball at two-thirds that speed to obtain:

$$v_0=60\ \text{mi/h}\times\frac{0.447\ \text{m/s}}{1\ \text{mi/h}}\approx 27\ \text{m/s}$$

There is no acceleration in the x direction, so the horizontal motion is one of constant velocity. Express the horizontal position of the ball as a function of time:

$$x = v_{0x}t = (v_0 \cos\theta_0)t \qquad (1)$$

Assuming that the release point of the ball is a distance y_0 above the ground, express the vertical position of the ball as a function of time:

$$\begin{aligned} y &= y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2 \\ &= y_0 + (v_0 \sin\theta_0)t + \tfrac{1}{2}a_y t^2 \end{aligned} \qquad (2)$$

Eliminating t between equations (1) and (2) yields:

$$y = y_0 + (\tan\theta_0)x + \left(\frac{a_y}{2v_0^2\cos^2\theta_0}\right)x^2$$

(a) If you throw the ball horizontally our equation becomes:

$$y = y_0 + \left(\frac{a_y}{2v_0^2}\right)x^2$$

Substitute numerical values to obtain:

$$y = 2.0\text{ m} + \left(\frac{-9.81\text{ m/s}^2}{2(27\text{ m/s})^2}\right)x^2$$

At impact, $y = 0$ and $x = R$:

$$0 = 2.0\text{ m} + \left(\frac{-9.81\text{ m/s}^2}{2(27\text{ m/s})^2}\right)R^2$$

Solving for R yields:

$$R \approx \boxed{17\text{ m}}$$

(b) For $\theta = 45°$ we have:

$$y = 2.0\text{ m} + (\tan 45°)x + \left(\frac{-9.81\text{ m/s}^2}{2(27\text{ m/s})^2\cos^2 45°}\right)x^2$$

At impact, $y = 0$ and $x = R$:

$$0 = 2.0\text{ m} + (\tan 45°)R + \left(\frac{-9.81\text{ m/s}^2}{2(27\text{ m/s})^2\cos^2 45°}\right)R^2$$

Use the quadratic formula or your graphing calculator to obtain:

$$R = \boxed{75\text{ m}}$$

(c) If you throw the ball horizontally from the top of a building that is 12 m high our equation becomes:

$$y = 14.0\text{ m} + \left(\frac{-9.81\text{ m/s}^2}{2(27\text{ m/s})^2}\right)x^2$$

At impact, $y = 0$ and $x = R$:

$$0 = 14.0\,\text{m} + \left(\frac{-9.81\,\text{m/s}^2}{2(27\,\text{m/s})^2}\right)R^2$$

Solve for R to obtain:

$$R = \boxed{45\,\text{m}}$$

(*d*) If you throw the ball at an angle of 45° from the top of a building that is 12 m high our equation becomes:

$$y = 14\,\text{m} + (\tan 45°)x + \left(\frac{-9.81\,\text{m/s}^2}{2(27\,\text{m/s})^2\cos^2 45°}\right)x^2$$

At impact, $y = 0$ and $x = R$:

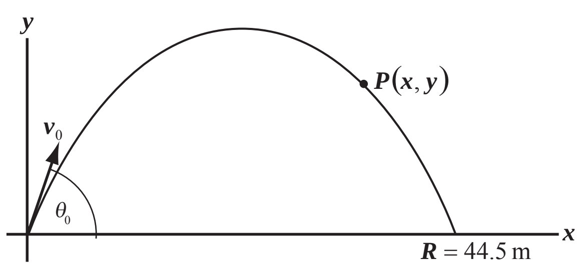
$$0 = 14\,\text{m} + (\tan 45°)R + \left(\frac{-9.81\,\text{m/s}^2}{2(27\,\text{m/s})^2\cos^2 45°}\right)R^2$$

Use the quadratic formula or your graphing calculator to obtain:

$$R = \boxed{85\,\text{m}}$$

37 •• In 1978, Geoff Capes of Great Britain threw a heavy brick a horizontal distance of 44.5 m. Find the approximate speed of the brick at the highest point of its flight, neglecting any effects due to air resistance. Assume the brick landed at the same height it was launched.

Picture the Problem We'll ignore the height of Geoff's release point above the ground and assume that he launched the brick at an angle of 45°. Because the velocity of the brick at the highest point of its flight is equal to the horizontal component of its initial velocity, we can use constant-acceleration equations to relate this velocity to the brick's x and y coordinates at impact. The diagram shows an appropriate coordinate system and the brick when it is at point P with coordinates (x, y).



Using a constant-acceleration equation, express the x and y coordinates of the brick as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

and

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

Because $x_0 = 0$, $y_0 = 0$, $a_y = -g$, and $a_x = 0$:

$$x = v_{0x}t$$
and
$$y = v_{0y}t - \tfrac{1}{2}gt^2$$

Eliminate t between these equations to obtain:

$$y = (\tan\theta_0)x - \frac{g}{2v_{0x}^2}x^2$$

where we have used $\tan\theta_0 = \dfrac{v_{0y}}{v_{0x}}$.

When the brick strikes the ground $y = 0$ and $x = R$:

$$0 = (\tan\theta_0)R - \frac{g}{2v_{0x}^2}R^2$$

where R is the range of the brick.

Solve for v_{0x} to obtain:

$$v_{0x} = \sqrt{\frac{gR}{2\tan\theta_0}}$$

Substitute numerical values and evaluate v_{0x}:

$$v_{0x} = \sqrt{\frac{(9.81\,\text{m/s}^2)(44.5\,\text{m})}{2\tan 45°}} \approx \boxed{15\,\text{m/s}}$$

Note that, at the brick's highest point, $v_y = 0$.

Position, Displacement, Velocity and Acceleration Vectors

38 • A wall clock has a minute hand with a length of 0.50 m and an hour hand with a length of 0.25 m. Take the center of the clock as the origin, and use a Cartesian coordinate system with the positive x axis pointing to 3 o'clock and the positive y axis pointing to 12 o'clock. Using unit vectors $\hat{\boldsymbol{i}}$ and $\hat{\boldsymbol{j}}$, express the position vectors of the tip of the hour hand ($\vec{\boldsymbol{A}}$) and the tip of the minute hand ($\vec{\boldsymbol{B}}$) when the clock reads (*a*) 12:00, (*b*) 3:00, (*c*) 6:00, (*d*) 9:00.

Picture the Problem Let the +y direction be straight up and the +x direction be to the right.

(*a*) At 12:00, both hands are positioned along the +y axis.

The position vector for the tip of the hour hand at12:00 is:

$$\vec{\boldsymbol{A}} = \boxed{(0.25\,\text{m})\hat{\boldsymbol{j}}}$$

The position vector for the tip of the minute hand at 12:00 is:

$$\vec{\boldsymbol{B}} = \boxed{(0.50\,\text{m})\hat{\boldsymbol{j}}}$$

(*b*) At 3:00, the minute hand is positioned along the +*y* axis, while the hour hand is positioned along the +*x* axis.

The position vector for the tip of the hour hand at 3:00 is: $\vec{A} = \boxed{(0.25\,\text{m})\hat{i}}$

The position vector for the tip of the minute hand at 3:00 is: $\vec{B} = \boxed{(0.50\,\text{m})\hat{j}}$

(*c*) At 6:00, the minute hand is positioned along the −*y* axis, while the hour hand is positioned along the +*y* axis.

The position vector for the tip of the hour hand at 6:00 is: $\vec{A} = \boxed{-(0.25\,\text{m})\hat{j}}$

The position vector for the tip of the minute hand at 6:00 is: $\vec{B} = \boxed{(0.50\,\text{m})\hat{j}}$

(*d*) At 9:00, the minute hand is positioned along the +*y* axis, while the hour hand is positioned along the −*x* axis.

The position vector for the tip of the hour hand at 9:00 is: $\vec{A} = \boxed{-(0.25\,\text{m})\hat{i}}$

The position vector for the tip of the minute hand at 9:00 is: $\vec{B} = \boxed{(0.50\,\text{m})\hat{j}}$

39 • [SSM] In Problem 38, find the displacements of the tip of each hand (that is, $\Delta\vec{A}$ and $\Delta\vec{B}$) when the time advances from 3:00 P.M. to 6:00 P.M.

Picture the Problem Let the +*y* direction be straight up, the +*x* direction be to the right, and use the vectors describing the ends of the hour and minute hands in Problem 38 to find the displacements $\Delta\vec{A}$ and $\Delta\vec{B}$.

The displacement of the minute hand as time advances from 3:00 P.M. to 6:00 P.M. is given by: $\Delta\vec{B} = \vec{B}_6 - \vec{B}_3$

From Problem 38: $\vec{B}_6 = (0.50\,\text{m})\hat{j}$ and $\vec{B}_3 = (0.50\,\text{m})\hat{j}$

Substitute and simplify to obtain: $\Delta\vec{B} = (0.50\,\text{m})\hat{j} - (0.50\,\text{m})\hat{j} = \boxed{0}$

The displacement of the hour hand as time advances from 3:00 P.M. to 6:00 P.M. is given by:

$$\Delta\vec{A} = \vec{A}_6 - \vec{A}_3$$

From Problem 38:

$$\vec{A}_6 = -(0.25\,\text{m})\hat{j} \text{ and } \vec{A}_3 = (0.25\,\text{m})\hat{i}$$

Substitute and simplify to obtain:

$$\Delta\vec{A} = \boxed{-(0.25\,\text{m})\hat{j} - (0.25\,\text{m})\hat{i}}$$

40 • In Problem 38, write the vector that describes the displacement of a fly if it quickly goes from the tip of the minute hand to the tip of the hour hand at 3:00 P.M.

Picture the Problem Let the positive y direction be straight up, the positive x direction be to the right, and use the vectors describing the ends of the hour and minute hands in Problem 38 to find the displacement $\vec{D}$ of the fly as it goes from the tip of the minute hand to the tip of the hour hand at 3:00 P.M.

The displacement of the fly is given by:

$$\vec{D} = \vec{A}_3 - \vec{B}_3$$

From Problem 38:

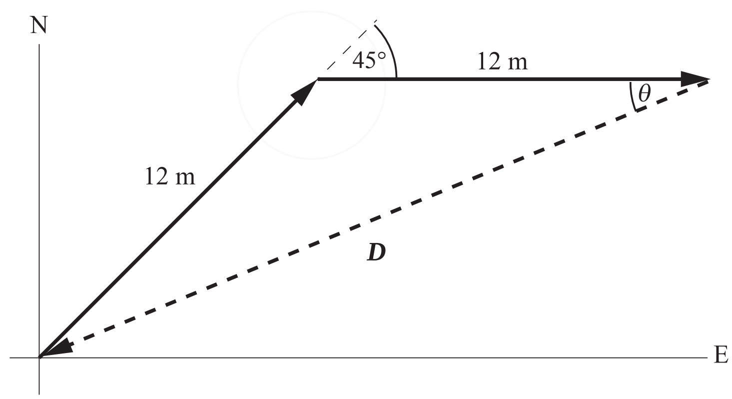
$$\vec{A}_3 = (0.25\,\text{m})\hat{i} \text{ and } \vec{B}_3 = (0.50\,\text{m})\hat{j}$$

Substitute for $\vec{A}_3$ and $\vec{B}_3$ to obtain:

$$\vec{D} = \boxed{(0.25\,\text{m})\,\hat{i} - (0.50\,\text{m})\hat{j}}$$

41 • A bear, awakening from winter hibernation, staggers directly northeast for 12 m and then due east for 12 m. Show each displacement graphically and graphically determine the single displacement that will take the bear back to her cave, to continue her hibernation.

Picture the Problem The single displacement for the bear to make it back to its cave is the vector $\vec{D}$. Its magnitude D and direction θ can be determined by drawing the bear's displacement vectors to scale.

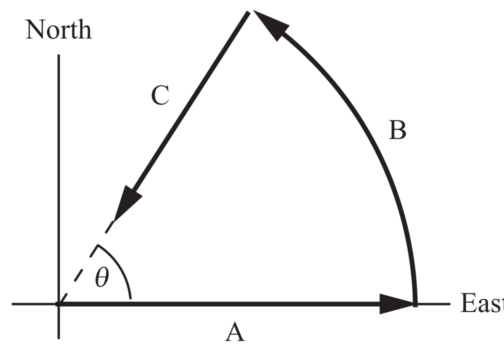


$$D \approx \boxed{22\,\text{m}} \text{ and } \boldsymbol{\theta} \approx \boxed{23°}$$

Remarks: The direction of $\vec{D}$ is 180° + θ ≈ 203°

42 • A scout walks 2.4 km due East from camp, then turns left and walks 2.4 km along the arc of a circle centered at the campsite, and finally walks 1.5 km directly toward the camp. (*a*) How far is the scout from camp at the end of his walk? (*b*) In what direction is the scout's position relative to the campsite? (*c*) What is the ratio of the final magnitude of the displacement to the total distance walked?

Picture the Problem The figure shows the paths walked by the Scout. The length of path A is 2.4 km; the length of path B is 2.4 km; and the length of path C is 1.5 km:



(*a*) Express the distance from the campsite to the end of path C:

$$2.4\text{ km} - 1.5\text{ km} = \boxed{0.9\,\text{km}}$$

(*b*) Determine the angle θ subtended by the arc at the origin (campsite):

$$\theta_{\text{radians}} = \frac{\text{arc length}}{\text{radius}} = \frac{2.4\,\text{km}}{2.4\,\text{km}}$$

$$= 1\,\text{rad} = 57.3°$$

His direction from camp is 1 rad North of East.

(*c*) Express the total distance as the sum of the three parts of his walk:

$$d_{\text{tot}} = d_{\text{east}} + d_{\text{arc}} + d_{\text{toward camp}}$$

Substitute the given distances to find the total:

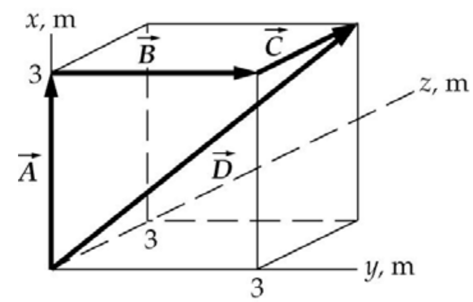
$$d_{\text{tot}} = 2.4\text{ km} + 2.4\text{ km} + 1.5\text{ km}$$
$$= 6.3\text{ km}$$

Express the ratio of the magnitude of his displacement to the total distance he walked and substitute to obtain a numerical value for this ratio:

$$\frac{\text{Magnitude of his displacement}}{\text{Total distance walked}} = \frac{0.9\,\text{km}}{6.3\,\text{km}} = \boxed{\frac{1}{7}}$$

43 •• [SSM] The faces of a cubical storage cabinet in your garage has 3.0-m-long edges that are parallel to the *xyz* coordinate planes. The cube has one corner at the origin. A cockroach, on the hunt for crumbs of food, begins at that corner and walks along three edges until it is at the far corner. (*a*) Write the roach's displacement using the set of $\hat{\boldsymbol{i}}$, $\hat{\boldsymbol{j}}$, and $\hat{\boldsymbol{k}}$ unit vectors, and (*b*) find the magnitude of its displacement.

Picture the Problem While there are several walking routes the cockroach could take to get from the origin to point C, its displacement will be the same for all of them. One possible route is shown in the figure.



(*a*) The roach's displacement $\vec{D}$ during its trip from the origin to point C is:

$$\vec{D} = \vec{A} + \vec{B} + \vec{C}$$
$$= \boxed{(3.0\,\text{m})\hat{\boldsymbol{i}} + (3.0\,\text{m})\hat{\boldsymbol{j}} + (3.0\,\text{m})\hat{\boldsymbol{k}}}$$

(*b*) The magnitude of the roach's displacement is given by:

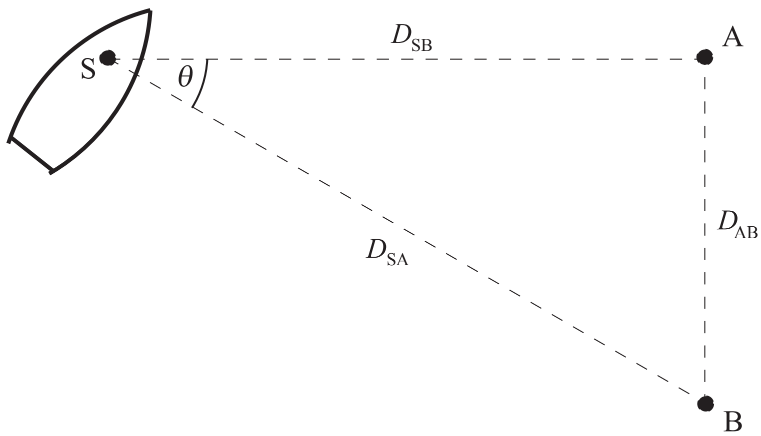
$$D = \sqrt{D_x^2 + D_y^2 + D_z^2}$$

Substitute numerical values for D_x, D_y, and D_z and evaluate D to obtain:

$$D = \sqrt{(3.0\,\text{m})^2 + (3.0\,\text{m})^2 + (3.0\,\text{m})^2}$$
$$= \boxed{5.2\,\text{m}}$$

44 • You are the navigator of a ship at sea. You receive radio signals from two transmitters A and B, which are 100 km apart, one due south of the other. The direction finder shows you that transmitter A is at a heading of 30º south of east from the ship, while transmitter B is due east. Calculate the distance between your ship and transmitter B.

Picture the Problem The diagram shows the locations of the transmitters relative to the ship and defines the distances separating the transmitters from each other and from the ship. We can find the distance between the ship and transmitter B using trigonometry.



Relate the distance between A and B to the distance from the ship to A and the angle θ:

$$\tan\theta = \frac{D_{AB}}{D_{SB}} \Rightarrow D_{SB} = \frac{D_{AB}}{\tan\theta}$$

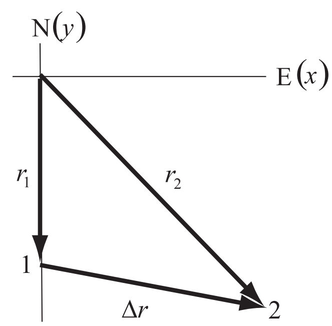
Substitute numerical values and evaluate D_{SB}:

$$D_{SB} = \frac{100\,\text{km}}{\tan 30°} = \boxed{1.7\times10^{5}\,\text{m}}$$

Velocity and Acceleration Vectors

45 • A stationary radar operator determines that a ship is 10 km due south of him. An hour later the same ship is 20 km due southeast. If the ship moved at constant speed and always in the same direction, what was its velocity during this time?

Picture the Problem For constant speed and direction, the instantaneous velocity is identical to the average velocity. Take the origin to be the location of the stationary radar and let the $+x$ direction be to the East and the $+y$ direction be to the North.



Express the average velocity:

$$\vec{\boldsymbol{v}}_{av} = \frac{\Delta\vec{\boldsymbol{r}}}{\Delta t} \qquad (1)$$

Determine the position vectors $\vec{\boldsymbol{r}}_1$ and $\vec{\boldsymbol{r}}_2$:

$$\vec{\boldsymbol{r}}_1 = (-10\,\text{km})\hat{\boldsymbol{j}}$$

and

$$\vec{\boldsymbol{r}}_2 = (14.1\,\text{km})\hat{\boldsymbol{i}} + (-14.1\,\text{km})\hat{\boldsymbol{j}}$$

Find the displacement vector $\Delta\vec{r}$:

$$\Delta\vec{r} = \vec{r}_2 - \vec{r}_1 = (14.1\,\text{km})\hat{i} + (-4.1\,\text{km})\hat{j}$$

Substitute for $\Delta\vec{r}$ and Δt in equation (1) to find the average velocity.

$$\vec{v}_{av} = \frac{(14.1\,\text{km})\hat{i} + (-4.1\,\text{km})\hat{j}}{1.0\,\text{h}} = \boxed{(14\,\text{km/h})\hat{i} + (-4.1\,\text{km/h})\hat{j}}$$

46 • A particle's position coordinates (x, y) are (2.0 m, 3.0 m) at $t = 0$; (6.0 m, 7.0 m) at $t = 2.0$ s; and (13 m, 14 m) at $t = 5.0$ s. (*a*) Find the magnitude of the average velocity from $t = 0$ to $t = 2.0$ s. (*b*) Find the magnitude of the average velocity from t = 0 to t = 5.0 s.

Picture the Problem The average velocity is the change in position divided by the elapsed time.

(*a*) The magnitude of the average velocity is given by:

$$|\vec{v}_{av}| = \frac{|\Delta\vec{r}|}{\Delta t}$$

Find the position vectors and the displacement vector:

$$\vec{r}_0 = (2.0\text{ m})\hat{i} + (3.0\text{ m})\hat{j}$$

$$\vec{r}_2 = (6.0\text{ m})\hat{i} + (7.0\text{ m})\hat{j}$$

and

$$\Delta\vec{r} = \vec{r}_2 - \vec{r}_1 = (4.0\text{ m})\hat{i} + (4.0\text{ m})\hat{j}$$

Find the magnitude of the displacement vector for the interval between $t = 0$ and $t = 2.0$ s:

$$|\Delta\vec{r}_{02}| = \sqrt{(4.0\text{ m})^2 + (4.0\text{ m})^2} = 5.66\text{ m}$$

Substitute to determine $|\vec{v}_{av}|$:

$$|\vec{v}_{av}| = \frac{5.66\,\text{m}}{2.0\,\text{s}} = \boxed{2.8\,\text{m/s}}$$

θ is given by:

$$\theta = \tan^{-1}\left(\frac{\Delta r_{y,02}}{\Delta r_{x,02}}\right) = \tan^{-1}\left(\frac{4.0\,\text{m}}{4.0\,\text{m}}\right) = \boxed{45°}$$

measured from the positive x axis.

(*b*) Repeat (*a*), this time using the displacement between $t = 0$ and $t = 5.0$ s to obtain:

$$\vec{r}_5 = (13\,\text{m})\hat{\boldsymbol{i}} + (14\,\text{m})\hat{\boldsymbol{j}}$$

$$\Delta\vec{r}_{05} = \vec{r}_5 - \vec{r}_0 = (11\,\text{m})\hat{\boldsymbol{i}} + (11\,\text{m})\hat{\boldsymbol{j}}.$$

$$|\Delta\vec{r}_{05}| = \sqrt{(11\,\text{m})^2 + (11\,\text{m})^2} = 15.6\,\text{m}$$

$$|\vec{v}_{\text{av}}| = \frac{15.6\,\text{m}}{5.0\,\text{s}} = \boxed{3.1\,\text{m/s}}.$$

and

$$\theta = \tan^{-1}\left(\frac{11\,\text{m}}{11\,\text{m}}\right) = \boxed{45°}$$

measured from the $+x$ axis.

47 • **[SSM]** A particle moving at a velocity of 4.0 m/s in the $+x$ direction is given an acceleration of 3.0 m/s^2 in the $+y$ direction for 2.0 s. Find the final speed of the particle.

Picture the Problem The magnitude of the velocity vector at the end of the 2 s of acceleration will give us its speed at that instant. This is a constant-acceleration problem.

Find the final velocity vector of the particle:

$$\begin{aligned}\vec{v} &= v_x\hat{\boldsymbol{i}} + v_y\hat{\boldsymbol{j}} = v_{x0}\hat{\boldsymbol{i}} + a_y t\hat{\boldsymbol{j}}\\ &= (4.0\,\text{m/s})\hat{\boldsymbol{i}} + (3.0\,\text{m/s}^2)(2.0\,\text{s})\hat{\boldsymbol{j}}\\ &= (4.0\,\text{m/s})\hat{\boldsymbol{i}} + (6.0\,\text{m/s})\hat{\boldsymbol{j}}\end{aligned}$$

The magnitude of $\vec{v}$ is:

$$|\vec{v}| = \sqrt{v_x^2 + v_y^2}$$

Substitute for v_x and v_y and evaluate $|\vec{v}|$:

$$|\vec{v}| = \sqrt{(4.0\,\text{m/s})^2 + (6.0\,\text{m/s})^2} = \boxed{7.2\,\text{m/s}}$$

48 • Initially, a swift-moving hawk is moving due west with a speed of 30 m/s; 5.0 s later it is moving due north with a speed of 20 m/s. (*a*) What are the magnitude and direction of $\Delta\vec{v}_{\text{av}}$ during this 5.0-s interval? (*b*) What are the magnitude and direction of $\vec{a}_{\text{av}}$ during this 5.0-s interval?

Picture the Problem Choose a coordinate system in which north coincides with the $+y$ direction and east with the $+x$ direction. Expressing the hawk's velocity vectors is the first step in determining $\Delta\vec{v}$ and $\vec{a}_{\text{av}}$.

(*a*) The change in the hawk's velocity during this interval is:

$$\Delta\vec{v}_{\text{av}} = \vec{v}_{\text{N}} - \vec{v}_{\text{W}}$$

$\vec{v}_{\text{W}}$ and $\vec{v}_{\text{N}}$ are given by:

$$\vec{v}_{\text{W}} = -(30\text{ m/s})\hat{i} \text{ and } \vec{v}_{\text{N}} = (20\text{ m/s})\hat{j}$$

Substitute for $\vec{v}_{\text{W}}$ and $\vec{v}_{\text{N}}$ and evaluate $\Delta\vec{v}$:

$$\begin{aligned}\Delta\vec{v}_{\text{av}} &= (20\text{ m/s})\hat{j} - \left[-(30\text{ m/s})\hat{i}\right]\\ &= (30\text{ m/s})\hat{i} + (20\text{ m/s})\hat{j}\end{aligned}$$

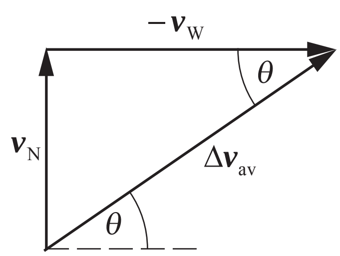
The magnitude of $\Delta\vec{v}_{\text{av}}$ is given by:

$$\left|\Delta\vec{v}_{\text{av}}\right| = \sqrt{\Delta v_x^2 + \Delta v_y^2}$$

Substitute numerical values and evaluate Δv:

$$\begin{aligned}\left|\Delta\vec{v}_{\text{av}}\right| &= \sqrt{(30\text{ m/s})^2 + (20\text{ m/s})^2}\\ &= \boxed{36\text{ m/s}}\end{aligned}$$

The direction of Δv is given by:



$$\theta = \tan^{-1}\left(\frac{\Delta v_y}{\Delta v_x}\right)$$

where θ is measured from the $+x$ axis.

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left(\frac{20\text{ m/s}}{30\text{ m/s}}\right) = \boxed{34°}$$

(*b*) The hawk's average acceleration during this interval is:

$$\vec{a}_{\text{av}} = \frac{\Delta\vec{v}_{\text{av}}}{\Delta t}$$

Substitute for $\Delta\vec{v}$ and Δt to obtain:

$$\begin{aligned}\vec{a}_{\text{av}} &= \frac{(30\text{ m/s})\hat{i} + (20\text{ m/s})\hat{j}}{5.0\text{ s}}\\ &= \left(6.0\text{ m/s}^2\right)\hat{i} + \left(4.0\text{ m/s}^2\right)\hat{j}\end{aligned}$$

The magnitude of $\vec{a}_{\text{av}}$ is given by:

$$\left|\vec{a}_{\text{av}}\right| = \sqrt{a_x^2 + a_y^2}$$

Substitute numerical values and evaluate $\left|\vec{a}_{\text{av}}\right|$:

$$\begin{aligned}\left|\vec{a}_{\text{av}}\right| &= \sqrt{\left(6.0\text{ m/s}^2\right) + \left(4.0\text{ m/s}^2\right)}\\ &= \boxed{7.2\text{ m/s}^2}\end{aligned}$$

The direction of $\vec{a}_{\text{av}}$ is given by:

$$\theta = \tan^{-1}\left(\frac{a_y}{a_x}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left(\frac{4.0\ \text{m/s}^2}{6.0\ \text{m/s}^2}\right) = \boxed{34°}$$

where θ is measured from the $+x$ axis.

Remarks: Because $\vec{a}_{\text{av}}$ is in the same direction as $\Delta\vec{v}_{\text{av}}$, the calculation of θ in Part (*b*) was not necessary.

49 • At $t = 0$, a particle located at the origin has a velocity of 40 m/s at $\theta = 45°$. At $t = 3.0$ s, the particle is at $x = 100$ m and $y = 80$ m and has a velocity of 30 m/s at $\theta = 50°$. Calculate (*a*) the average velocity and (*b*) the average acceleration of the particle during this 3.0-s interval.

Picture the Problem The initial and final positions and velocities of the particle are given. We can find the average velocity and average acceleration using their definitions by first calculating the given displacement and velocities using unit vectors $\hat{\boldsymbol{i}}$ and $\hat{\boldsymbol{j}}$.

(*a*) The average velocity of the particle is the ratio of its displacement to the elapsed time:

$$\vec{v}_{\text{av}} = \frac{\Delta\vec{r}}{\Delta t}$$

The displacement of the particle during this interval of time is:

$$\Delta\vec{r} = (100\,\text{m})\hat{\boldsymbol{i}} + (80\,\text{m})\hat{\boldsymbol{j}}$$

Substitute to find the average velocity:

$$\vec{v}_{\text{av}} = \frac{(100\,\text{m})\hat{\boldsymbol{i}} + (80\,\text{m})\hat{\boldsymbol{j}}}{3.0\,\text{s}} = (33.3\,\text{m/s})\hat{\boldsymbol{i}} + (26.7\,\text{m/s})\hat{\boldsymbol{j}} = \boxed{(33\,\text{m/s})\hat{\boldsymbol{i}} + (27\,\text{m/s})\hat{\boldsymbol{j}}}$$

(*b*) The average acceleration is:

$$\vec{a}_{\text{av}} = \frac{\Delta\vec{v}}{\Delta t} = \frac{\vec{v}_2 - \vec{v}_1}{\Delta t}$$

$\vec{v}_1$ and $\vec{v}_2$ are given by:

$$\vec{v}_1 = [(40\,\text{m/s})\cos 45°]\hat{\boldsymbol{i}} + [(40\,\text{m/s})\sin 45°]\hat{\boldsymbol{j}} = (28.28\,\text{m/s})\hat{\boldsymbol{i}} + (28.28\,\text{m/s})\hat{\boldsymbol{j}}$$

and

$$\vec{v}_2 = [(30\,\text{m/s})\cos 50°]\hat{\boldsymbol{i}} + [(30\,\text{m/s})\sin 50°]\hat{\boldsymbol{j}} = (19.28\,\text{m/s})\hat{\boldsymbol{i}} + (22.98\,\text{m/s})\hat{\boldsymbol{j}}$$

Substitute for $\vec{v}_1$ and $\vec{v}_2$ and evaluate $\vec{a}_{\text{av}}$:

$$\vec{a}_{\text{av}} = \frac{(19.28\,\text{m/s})\hat{i} + (22.98\,\text{m/s})\hat{j} - \left[(28.28\,\text{m/s})\hat{i} + (28.28\,\text{m/s})\hat{j}\right]}{3.0\,\text{s}}$$

$$= \frac{(-9.00\,\text{m/s})\hat{i} + (-5.30\,\text{m/s})\hat{j}}{3.0\,\text{s}} = \boxed{(-3.0\,\text{m/s}^2)\hat{i} + (-1.8\,\text{m/s}^2)\hat{j}}$$

50 •• At time zero, a particle is at $x = 4.0$ m and $y = 3.0$ m and has velocity $\vec{v}$ = (2.0 m/s) $\hat{i}$ + (–9.0 m/s) $\hat{j}$. The acceleration of the particle is constant and is given by $\vec{a}$ = (4.0 m/s²) $\hat{i}$ + (3.0 m/s²) $\hat{j}$. (*a*) Find the velocity at $t = 2.0$ s. (*b*) Express the position vector at $t = 4.0$ s in terms of $\hat{i}$ and $\hat{j}$. In addition, give the magnitude and direction of the position vector at this time.

Picture the Problem The acceleration is constant so we can use the constant-acceleration equations in vector form to find the velocity at $t = 2.0$ s and the position vector at $t = 4.0$ s.

(*a*) The velocity of the particle, as a function of time, is given by:

$$\vec{v} = \vec{v}_0 + \vec{a}t$$

Substitute for $\vec{v}_0$ and $\vec{a}$ to find $\vec{v}(2.0\,\text{s})$:

$$\vec{v}(2.0\,\text{s}) = (2.0\,\text{m/s})\hat{i} + (-9.0\,\text{m/s})\hat{j} + \left[(4.0\,\text{m/s}^2)\hat{i} + (3.0\,\text{m/s}^2)\hat{j}\right](2.0\,\text{s})$$

$$= \boxed{(10\,\text{m/s})\hat{i} + (-3.0\,\text{m/s})\hat{j}}$$

(*b*) Express the position vector as a function of time:

$$\vec{r} = \vec{r}_0 + \vec{v}_0 t + \tfrac{1}{2}\vec{a}t^2$$

Substitute numerical values and evaluate $\vec{r}$:

$$\vec{r} = (4.0\,\text{m})\hat{i} + (3.0\,\text{m})\hat{j} + \left[(2.0\,\text{m/s})\hat{i} + (-9.0\,\text{m/s})\hat{j}\right](4.0\,\text{s})$$
$$+ \tfrac{1}{2}\left[(4.0\,\text{m/s}^2)\hat{i} + (3.0\,\text{m/s}^2)\hat{j}\right](4.0\,\text{s})^2$$
$$= (44.0\,\text{m})\hat{i} + (-9.0\,\text{m})\hat{j}$$
$$= \boxed{(44\,\text{m})\hat{i} + (-9.0\,\text{m})\hat{j}}$$

The magnitude of $\vec{r}$ is given by $r = \sqrt{r_x^2 + r_y^2}$. Substitute numerical values and evaluate r(4.0 s):

$$r(4.0\,\text{s}) = \sqrt{(44.0\,\text{m})^2 + (-9.0\,\text{m})^2}$$
$$= \boxed{45\,\text{m}}$$

The direction of $\vec{r}$ is given by $\theta = \tan^{-1}\left(\dfrac{r_y}{r_x}\right)$**.** Because $\vec{r}$ is in the 4th quadrant, its direction measured from the $+x$ axis is:

$$\theta = \tan^{-1}\left(\frac{-9.0\,\text{m}}{44.0\,\text{m}}\right) = -11.6° = \boxed{-12°}$$

51 •• [SSM] A particle has a position vector given by $\vec{r} = (30t)\hat{\boldsymbol{i}} + (40t - 5t^2)\hat{\boldsymbol{j}}$, where r is in meters and t is in seconds. Find the instantaneous-velocity and instantaneous-acceleration vectors as functions of time t.

Picture the Problem The velocity vector is the time-derivative of the position vector and the acceleration vector is the time-derivative of the velocity vector.

Differentiate $\vec{r}$ with respect to time:

$$\vec{v} = \frac{d\vec{r}}{dt} = \frac{d}{dt}\left[(30t)\hat{\boldsymbol{i}} + \left(40t - 5t^2\right)\hat{\boldsymbol{j}}\right]$$

$$= \boxed{30\hat{\boldsymbol{i}} + (40 - 10t)\hat{\boldsymbol{j}}}$$

where $\vec{v}$ has units of m/s if t is in seconds.

Differentiate $\vec{v}$ with respect to time:

$$\vec{a} = \frac{d\vec{v}}{dt} = \frac{d}{dt}\left[30\hat{\boldsymbol{i}} + (40 - 10t)\hat{\boldsymbol{j}}\right]$$

$$= \boxed{\left(-10\,\text{m/s}^2\right)\hat{\boldsymbol{j}}}$$

52 •• A particle has a constant acceleration of $\vec{a} = (6.0\ \text{m/s}^2)\hat{\boldsymbol{i}} + (4\ .0\ \text{m/s}^2)\hat{\boldsymbol{j}}$. At time $t = 0$, the velocity is zero and the position vector is $\vec{r}_0 = (10\ \text{m})\hat{\boldsymbol{i}}$. (*a*) Find the velocity and position vectors as functions of time t. (*b*) Find the equation of the particle's path in the xy plane and sketch the path.

Picture the Problem We can use constant-acceleration equations in vector form to find the velocity and position vectors as functions of time t. In (*b*), we can eliminate t from the equations giving the x and y components of the particle to find an expression for y as a function of x.

(*a*) Use $\vec{v} = \vec{v}_0 + \vec{a}t$ with $\vec{v}_0 = 0$ to find $\vec{v}$:

$$\vec{v} = \boxed{\left[\left(6.0\ \text{m/s}^2\right)\hat{\boldsymbol{i}} + \left(4.0\ \text{m/s}^2\right)\hat{\boldsymbol{j}}\right]t}$$

Use $\vec{r} = \vec{r}_0 + \vec{v}_0 t + \frac{1}{2}\vec{a}t^2$ with $\vec{r}_0 = (10\,\text{m})\hat{\boldsymbol{i}}$ to find $\vec{r}$:

$$\vec{r} = \boxed{\left[(10\ \text{m}) + \left(3.0\ \text{m/s}^2\right)t^2\right]\hat{\boldsymbol{i}} + \left[\left(2.0\ \text{m/s}^2\right)t^2\right]\hat{\boldsymbol{j}}}$$

(*b*) Obtain the *x* and *y* components of the path from the vector equation in (*a*):

$$x = 10\ \text{m} + \left(3.0\ \text{m/s}^2\right)t^2$$

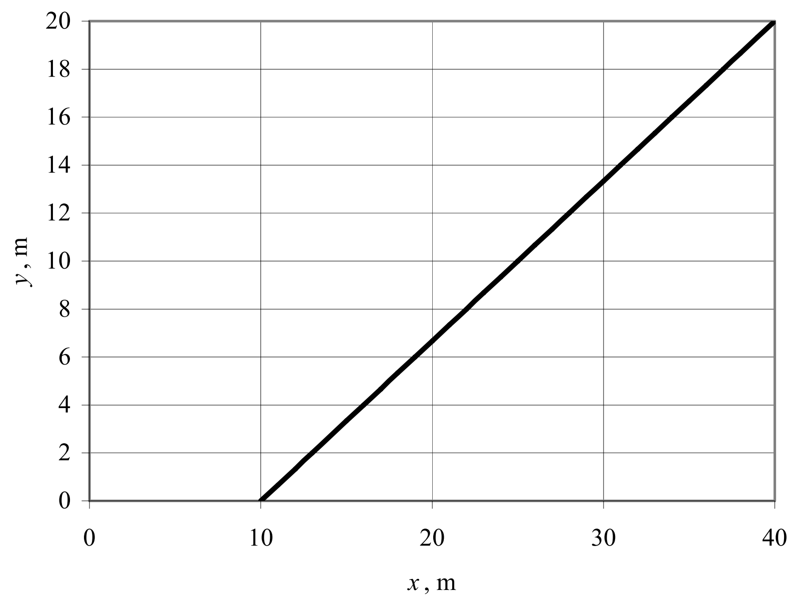
and

$$y = \left(2.0\ \text{m/s}^2\right)t^2$$

Eliminate *t* from these equations and solve for *y* to obtain:

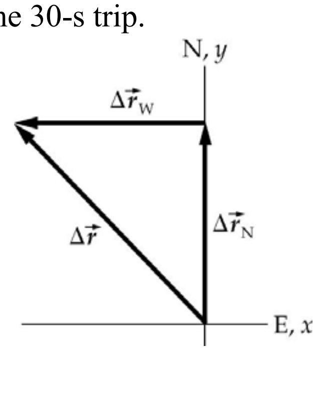
$$\boxed{y = \tfrac{2}{3}x - \tfrac{20}{3}\ \text{m}}$$

The graph of $y = \frac{2}{3}x - \frac{20}{3}\ \text{m}$ is shown below. Note that the path in the *xy* plane is a straight line.



53 •• Starting from rest at a dock, a motor boat on a lake heads north while gaining speed at a constant 3.0 m/s^2 for 20 s. The boat then heads west and continues for 10 s at the speed that it had at 20 s. (*a*) What is the average velocity of the boat during the 30-s trip? (*b*) What is the average acceleration of the boat during the 30-s trip? (*c*) What is the displacement of the boat during the 30-s trip?

Picture the Problem The displacements of the boat are shown in the following figure. Let the +*x* direction be to the east and the +*y* direction be to the north. We need to determine each of the displacements in order to calculate the average velocity of the boat during the 30-s trip.



(*a*) The average velocity of the boat is given by:

$$\vec{v}_{av} = \frac{\Delta\vec{r}}{\Delta t} \quad (1)$$

The total displacement of the boat is given by:

$$\Delta\vec{r} = \Delta\vec{r}_N + \Delta\vec{r}_W = \tfrac{1}{2}a_N(\Delta t_N)^2\,\hat{j} + v_W\Delta t_W(-\hat{i}) \quad (2)$$

To calculate the displacement we first have to find the speed after the first 20 s:

$$v_W = v_{N,f} = a_N\Delta t_N$$

Substitute numerical values and evaluate v_W:

$$v_W = (3.0\ \text{m/s}^2)(20\ \text{s}) = 60\ \text{m/s}$$

Substitute numerical values in equation (2) and evaluate $\Delta\vec{r}(30\ \text{s})$:

$$\Delta\vec{r}(30\ \text{s}) = \tfrac{1}{2}(3.0\ \text{m/s}^2)(20\ \text{s})^2\,\hat{j} - (60\ \text{m/s})(10\ \text{s})\,\hat{i} = (600\ \text{m})\hat{j} - (600\ \text{m})\hat{i}$$

Substitute numerical values in equation (1) to find the boat's average velocity:

$$\vec{v}_{av} = \frac{\Delta\vec{r}}{\Delta t} = \frac{(600\ \text{m})(-\hat{i}+\hat{j})}{30\ \text{s}} = \boxed{(20\ \text{m/s})(-\hat{i}+\hat{j})}$$

(*b*) The average acceleration of the boat is given by:

$$\vec{a}_{av} = \frac{\Delta\vec{v}}{\Delta t} = \frac{\vec{v}_f - \vec{v}_i}{\Delta t}$$

Substitute numerical values and evaluate $\vec{a}_{av}$:

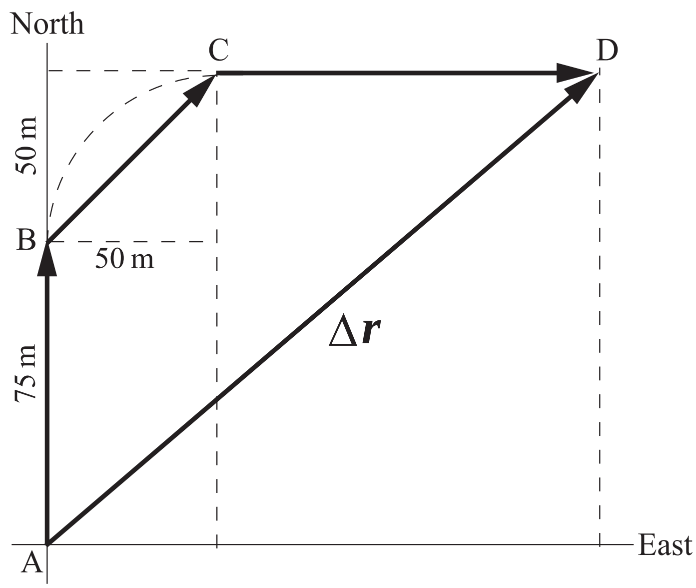
$$\vec{a}_{av} = \frac{(-60\ \text{m/s})\hat{i} - 0}{30\ \text{s}} = \boxed{(-2.0\ \text{m/s}^2)\hat{i}}$$

(*c*) The displacement of the boat from the dock at the end of the 30-s trip was one of the intermediate results we obtained in Part (*a*).

$$\Delta\vec{r} = (600\ \text{m})\hat{j} + (-600\ \text{m})\hat{i} = \boxed{(600\ \text{m})(-\hat{i}+\hat{j})}$$

54 •• Starting from rest at point A, you ride your motorcycle north to point B 75.0 m away, increasing speed at steady rate of 2.00 m/s^2. You then gradually turn toward the east along a circular path of radius 50.0 m at constant speed from B to point C until your direction of motion is due east at C. You then continue eastward, slowing at a steady rate of 1.00 m/s^2 until you come to rest at point D. (*a*) What is your average velocity and acceleration for the trip from A to D? (*b*) What is your displacement during your trip from A to C? (*c*) What distance did you travel for the entire trip from A to D?

Picture the Problem The following diagram summarizes the information given in the problem statement. Let the $+x$ direction be to the east and the $+y$ direction be to the north. To find your average velocity you'll need to find your displacement $\Delta\vec{r}$ and the total time required for you to make this trip. You can express $\Delta\vec{r}$ as the sum of your displacements $\Delta\vec{r}_{AB}$, $\Delta\vec{r}_{BC}$, and $\Delta\vec{r}_{CD}$. The total time for your trip is the sum of the times required for each of the segments. Because the acceleration is constant (but different) along each of the segments of your trip, you can use constant-acceleration equations to find each of these quantities.



(*a*) The average velocity for your trip is given by:

$$\vec{v}_{av} = \frac{\Delta\vec{r}}{\Delta t} \qquad (1)$$

The total displacement for your trip is the sum of the displacements along the three segments:

$$\Delta\vec{r} = \Delta\vec{r}_{AB} + \Delta\vec{r}_{BC} + \Delta\vec{r}_{CD} \qquad (2)$$

The total time for your trip is the sum of the times for the three segments:

$$\Delta t = \Delta t_{AB} + \Delta t_{BC} + \Delta t_{CD} \qquad (3)$$

The displacements of the three segments of the trip are:

$$\Delta\vec{r}_{AB} = 0\hat{\boldsymbol{i}} + (75.0\text{ m})\hat{\boldsymbol{j}}\,,$$

$$\Delta\vec{r}_{BC} = (50.0\text{ m})\hat{\boldsymbol{i}} + (50.0\text{ m})\hat{\boldsymbol{j}}\,,$$

and

$$\Delta\vec{r}_{CD} = \Delta r_{CD}\hat{\boldsymbol{i}} + 0\hat{\boldsymbol{j}}$$

In order to find Δx_{CD}, you need to find the time for the C to D segment of the trip. Use a constant-acceleration equation to express Δx_{CD}:

$$\Delta x_{CD} = v_C \Delta t_{CD} + \tfrac{1}{2} a_{CD} (\Delta t_{CD})^2 \quad (4)$$

Because $v_C = v_B$:

$$v_C = v_B = v_A + a_{AB}\Delta t_{AB}$$

or, because $v_A = 0$,

$$v_C = a_{AB}\Delta t_{AB} \quad (5)$$

Use a constant-acceleration equation to relate Δt_{AB} to Δy_{AB}:

$$\Delta y_{AB} = v_A \Delta t_{AB} + \tfrac{1}{2} a_{AB} (\Delta t_{AB})^2$$

or, because $v_A = 0$,

$$\Delta y_{AB} = \tfrac{1}{2} a_{AB} (\Delta t_{AB})^2 \Rightarrow \Delta t_{AB} = \sqrt{\frac{2\Delta y_{AB}}{a_{AB}}}$$

Substitute numerical values and evaluate Δt_{AB}:

$$\Delta t_{AB} = \sqrt{\frac{2(75.0\text{ m})}{2.00\text{ m/s}^2}} = 8.660\text{ s}$$

Substitute for Δt_{AB} in equation (5) to obtain:

$$v_C = a_{AB}\sqrt{\frac{2\Delta y_{AB}}{a_{AB}}} = \sqrt{2a_{AB}\Delta y_{AB}}$$

Substitute numerical values and evaluate v_C:

$$v_C = \sqrt{2(2.00\text{ m/s}^2)(75.0\text{ m})} = 17.32\text{ m/s}$$

The time required for the circular segment BC is given by:

$$\Delta t_{BC} = \frac{\tfrac{1}{2}\pi r}{v_B}$$

Substitute numerical values and evaluate Δt_{BC}:

$$\Delta t_{BC} = \frac{\tfrac{1}{2}\pi (50.0\text{ m})}{17.32\text{ m/s}} = 4.535\text{ s}$$

The time to travel from C to D is given by:

$$\Delta t_{CD} = \frac{\Delta v_{CD}}{a_{CD}} = \frac{v_D - v_C}{a_{CD}}$$

or, because $v_D = 0$,

$$\Delta t_{CD} = \frac{-v_C}{a_{CD}}$$

Substitute numerical values and evaluate Δt_{CD}:

$$\Delta t_{CD} = \frac{-17.32\text{ m/s}}{-1.00\text{ m/s}^2} = 17.32\text{ s}$$

Now we can use equation (4) to evaluate Δt_{CD}:

$$\Delta x_{\mathrm{CD}} = (17.32\ \mathrm{m/s})(17.32\ \mathrm{s}) + \tfrac{1}{2}(-1.00\ \mathrm{m/s^2})(17.32\ \mathrm{s})^2 = 150\ \mathrm{m}$$

The three displacements that you need to add in order to get $\Delta\vec{r}$ are:

$\Delta\vec{r}_{\mathrm{AB}} = 0\hat{i} + (75.0\ \mathrm{m})\hat{j}$,
$\Delta\vec{r}_{\mathrm{BC}} = (50.0\ \mathrm{m})\hat{i} + (50.0\ \mathrm{m})\hat{j}$,
and
$\Delta\vec{r}_{\mathrm{CD}} = (150\ \mathrm{m})\hat{i} + 0\hat{j}$

Substitute in equation (2) to obtain:

$$\begin{aligned}\Delta\vec{r} &= 0\hat{i} + (75.0\ \mathrm{m})\hat{j} + (50.0\ \mathrm{m})\hat{i} + (50.0\ \mathrm{m})\hat{j} + (150\ \mathrm{m})\hat{i} + 0\hat{j}\\ &= (200\ \mathrm{m})\hat{i} + (125\ \mathrm{m})\hat{j}\end{aligned}$$

Substituting in equation (3) for Δt_{AB}, Δt_{BC}, and Δt_{CD} yields:

$$\Delta t = 8.660\ \mathrm{s} + 4.535\ \mathrm{s} + 17.32\ \mathrm{s} = 30.51\ \mathrm{s}$$

Use equation (1) to find $\vec{v}_{\mathrm{av}}$:

$$\begin{aligned}\vec{v}_{\mathrm{av}} &= \frac{(200\ \mathrm{m})\hat{i} + (125\ \mathrm{m})\hat{j}}{30.51\ \mathrm{s}}\\ &= \boxed{(6.56\ \mathrm{m/s})\hat{i} + (4.10\ \mathrm{m/s})\hat{j}}\end{aligned}$$

Because the final and initial velocities are zero, the average acceleration is zero.

(*b*) Express your displacement from A to C as the sum of the displacements from A to B and from B to C:

$$\Delta\vec{r}_{\mathrm{AC}} = \Delta\vec{r}_{\mathrm{AB}} + \Delta\vec{r}_{\mathrm{BC}}$$

From (*a*) you have:

$\Delta\vec{r}_{\mathrm{AB}} = 0\hat{i} + (75.0\ \mathrm{m})\hat{j}$
and
$\Delta\vec{r}_{\mathrm{BC}} = (50.0\ \mathrm{m})\hat{i} + (50.0\ \mathrm{m})\hat{j}$

Substitute and simplify to obtain:

$$\begin{aligned}\Delta\vec{r}_{\mathrm{AC}} &= 0\hat{i} + (75.0\ \mathrm{m})\hat{j} + (50.0\ \mathrm{m})\hat{i}\\ &\quad + (50.0\ \mathrm{m})\hat{j}\\ &= \boxed{(50.0\ \mathrm{m})\hat{i} + (125\ \mathrm{m})\hat{j}}\end{aligned}$$

(*c*) Express the total distance you traveled as the sum of the distances traveled along the three segments:

$d_{\mathrm{tot}} = d_{\mathrm{AB}} + d_{\mathrm{BC}} + d_{\mathrm{CD}}$
where $d_{\mathrm{BC}} = \tfrac{1}{2}\pi r$ and r is the radius of the circular arc.

Substituting for d_{BC} yields: $d_{tot} = d_{AB} + \frac{1}{2}\pi r + d_{CD}$

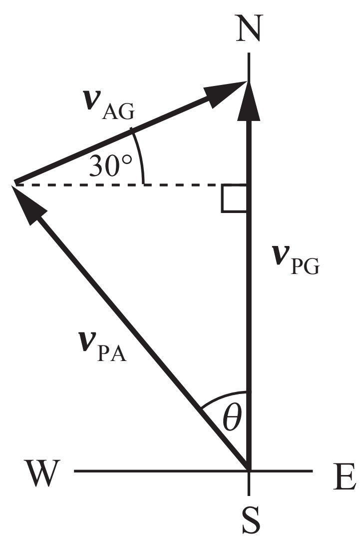
Substitute numerical values and evaluate d_{tot}:

$$d_{tot} = 75.0\text{ m} + \tfrac{1}{2}\pi(50.0\text{ m}) + 150\text{ m} = \boxed{304\text{ m}}$$

Relative Velocity

55 •• A plane flies at an airspeed of 250 km/h. A wind is blowing at 80 km/h toward the direction 60º east of north. (*a*) In what direction should the plane head in order to fly due north relative to the ground? (*b*) What is the speed of the plane relative to the ground?

Picture the Problem Choose a coordinate system in which north is the +*y* direction and east is the +*x* direction. Let θ be the angle between north and the direction of the plane's heading. The velocity of the plane relative to the ground, $\vec{v}_{PG}$, is the sum of the velocity of the plane relative to the air, $\vec{v}_{PA}$, and the velocity of the air relative to the ground, $\vec{v}_{AG}$. That is, $\vec{v}_{PG} = \vec{v}_{PA} + \vec{v}_{AG}$. The pilot must head in such a direction that the east-west component of $\vec{v}_{PG}$ is zero in order to make the plane fly due north.



(*a*) From the diagram one can see that: $v_{AG}\cos 30° = v_{PA}\sin\theta$

Solving for θ yields:

$$\theta = \sin^{-1}\left[\frac{v_{AG}\cos 30°}{v_{PA}}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{(80\text{ km/h})\cos 30°}{250\text{ km/h}}\right] = 16.1° \approx \boxed{16°\ \text{west of north}}$$

(*b*) Because the plane is headed due north, add the north components of $\vec{v}_{PA}$ and $\vec{v}_{AG}$ to determine the plane's ground speed:

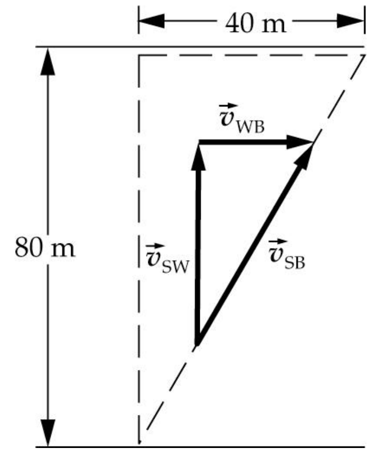
$$\left|\vec{v}_{PG}\right| = (250\text{ km/h})\cos 16.1° + (80\text{ km/h})\sin 30° = \boxed{280\text{ km/s}}$$

56 •• A swimmer *heads* directly across a river, swimming at 1.6 m/s relative to the water. She arrives at a point 40 m downstream from the point directly across the river, which is 80 m wide. (*a*) What is the speed of the river current? (*b*) What is the swimmer's speed relative to the shore? (*c*) In what direction should the swimmer head in order to arrive at the point directly opposite her starting point?

Picture the Problem Let $\vec{v}_{SB}$ represent the velocity of the swimmer relative to the shore; $\vec{v}_{SW}$ the velocity of the swimmer relative to the water; and $\vec{v}_{WB}$ the velocity of the water relative to the shore; i.e.,

$$\vec{v}_{SB} = \vec{v}_{SW} + \vec{v}_{WB}$$

The current of the river causes the swimmer to drift downstream.



(*a*) The triangles shown in the figure are similar right triangles. Set up a proportion between their sides and solve for the speed of the water relative to the bank:

$$\frac{v_{WB}}{v_{SW}} = \frac{40\,\text{m}}{80\,\text{m}}$$

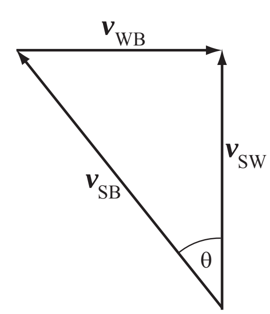
and

$$v_{WB} = \tfrac{1}{2}(1.6\,\text{m/s}) = \boxed{0.80\,\text{m/s}}$$

(*b*) Use the Pythagorean Theorem to solve for the swimmer's speed relative to the shore:

$$v_{SB} = \sqrt{v_{SW}^2 + v_{WB}^2} = \sqrt{(1.6\,\text{m/s})^2 + (0.80\,\text{m/s})^2} = \boxed{1.8\,\text{m/s}}$$

(*c*) The swimmer should head in a direction such that the upstream component of her velocity relative to the shore ($\vec{v}_{SB}$) is equal to the speed of the water relative to the shore ($\vec{v}_{WB}$):



Referring to the diagram, relate $\sin\theta$ to $\vec{v}_{WB}$ and $\vec{v}_{SB}$:

$$\sin\theta = \frac{v_{WB}}{v_{SB}} \Rightarrow \theta = \sin^{-1}\left(\frac{v_{WB}}{v_{SB}}\right)$$

Substitute numerical values and evaluate θ:

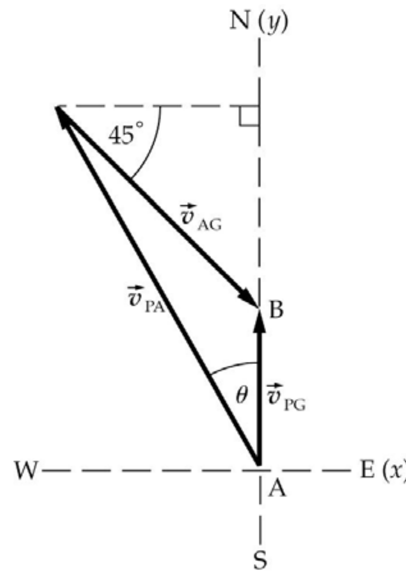
$$\theta = \sin^{-1}\left(\frac{0.80\,\text{m/s}}{1.8\,\text{m/s}}\right) = \boxed{26^\circ}$$

57 •• [SSM] A small plane departs from point A heading for an airport 520 km due north at point B. The airspeed of the plane is 240 km/h and there is a steady wind of 50 km/h blowing directly toward the southeast. Determine the proper heading for the plane and the time of flight.

Picture the Problem Let the velocity of the plane relative to the ground be represented by $\vec{v}_{\text{PG}}$; the velocity of the plane relative to the air by $\vec{v}_{\text{PA}}$, and the velocity of the air relative to the ground by $\vec{v}_{\text{AG}}$. Then

$$\vec{v}_{\text{PG}} = \vec{v}_{\text{PA}} + \vec{v}_{\text{AG}} \quad (1)$$

Choose a coordinate system with the origin at point A, the +*x* direction to the east, and the +*y* direction to the north. θ is the angle between north and the direction of the plane's heading. The pilot must head so that the east-west component of $\vec{v}_{\text{PG}}$ is zero in order to make the plane fly due north.



Use the diagram to express the condition relating the eastward component of $\vec{v}_{\text{AG}}$ and the westward component of $\vec{v}_{\text{PA}}$. This must be satisfied if the plane is to stay on its northerly course. [*Note*: this is equivalent to equating the *x*-components of equation (1).]

$$v_{\text{AG}} \cos 45° = v_{\text{PA}} \sin\theta$$

Now solve for θ to obtain:

$$\theta = \sin^{-1}\left[\frac{v_{\text{AG}} \cos 45°}{v_{\text{PA}}}\right]$$

Substitute numerical values and evaluate θ:

$$\boldsymbol{\theta} = \sin^{-1}\left[\frac{(50\text{ km/h})\cos 45°}{240\text{ km/h}}\right] = 8.47°$$

$$= \boxed{8.5°}$$

Add the north components of $\vec{v}_{\text{PA}}$ and $\vec{v}_{\text{AG}}$ to find the velocity of the plane relative to the ground:

$$v_{\text{PG}} + v_{\text{AG}} \sin 45° = v_{\text{PA}} \cos 8.47°$$

Solving for v_{PG} yields: $v_{PG} = v_{PA}\cos 8.47° - v_{AG}\sin 45°$

Substitute numerical values and evaluate v_{PG} to obtain:

$$v_{PG} = (240\ \text{km/h})\cos 8.47° - (50\ \text{km/h})\sin 45° = 202.0\ \text{km/h}$$

The time of flight is given by: $t_{flight} = \dfrac{\text{distance travelled}}{v_{PG}}$

Substitute numerical values and evaluate t_{flight}: $t_{flight} = \dfrac{520\ \text{km}}{202.0\ \text{km/h}} = \boxed{2.57\ \text{h}}$

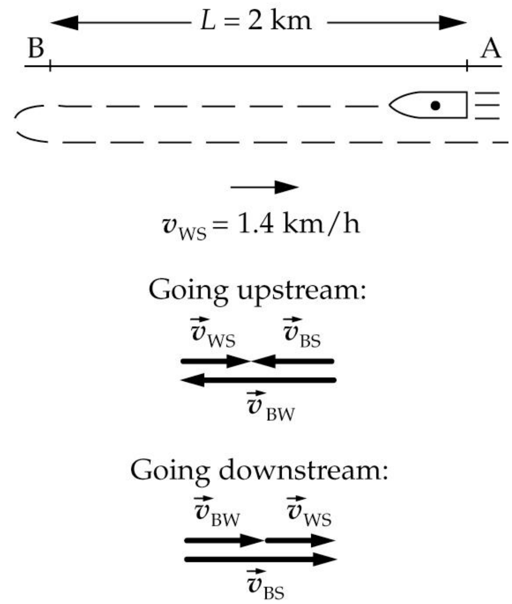
58 •• Two boat landings are 2.0 km apart on the same bank of a stream that flows at 1.4 km/h. A motorboat makes the round trip between the two landings in 50 min. What is the speed of the boat relative to the water?

Picture the Problem Let $\vec{v}_{BS}$ be the velocity of the boat relative to the shore; $\vec{v}_{BW}$ be the velocity of the boat relative to the water; and $\vec{v}_{WS}$ represent the velocity of the water relative to the shore. Independently of whether the boat is going upstream or downstream:

$$\vec{v}_{BS} = \vec{v}_{BW} + \vec{v}_{WS}$$

Going upstream, the speed of the boat relative to the shore is reduced by the speed of the water relative to the shore.

Going downstream, the speed of the boat relative to the shore is increased by the same amount.



For the upstream leg of the trip: $v_{BS} = v_{BW} - v_{WS}$

For the downstream leg of the trip: $v_{BS} = v_{BW} + v_{WS}$

Express the total time for the trip in terms of the times for its upstream and downstream legs:

$$t_{total} = t_{upstream} + t_{downstream} = \frac{L}{v_{BW} - v_{WS}} + \frac{L}{v_{BW} + v_{WS}}$$

Multiply both sides of the equation by $(v_{\text{BW}} - v_{\text{WS}})(v_{\text{BW}} + v_{\text{WS}})$ (the product of the- denominators) and rearrange the terms to obtain:

$$v_{\text{BW}}^2 - \frac{2L}{t_{\text{total}}} v_{\text{BW}} - v_{\text{WS}}^2 = 0$$

Substituting numerical values gives:

$$v_{\text{BW}}^2 - \frac{2(2.0\,\text{km})}{\frac{5}{6}\,\text{h}} v_{\text{BW}} - (1.4\,\text{km/h})^2 = 0$$

or

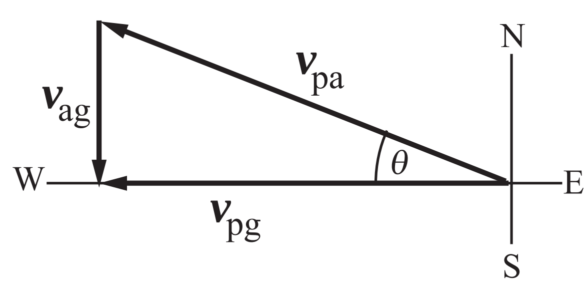
$$v_{\text{BW}}^2 - (4.80\,\text{km/h})v_{\text{BW}} - 1.96\,(\text{km})^2/\text{h}^2 = 0$$

Use the quadratic formula or your graphing calculator to solve the quadratic equation for v_{BW} (Note that only the positive root is physically meaningful.):

$$v_{\text{BW}} = \boxed{5.2\,\text{km/h}}$$

59 •• During a radio-controlled model-airplane competition, each plane must fly from the center of a 1.0-km-radius circle to any point on the circle and back to the center. The winner is the plane that has the shortest round-trip time. The contestants are free to fly their planes along any route as long as the plane begins at the center, travels to the circle, and then returns to the center. On the day of the race, a steady wind blows out of the north at 5.0 m/s. Your plane can maintain an air speed of 15 m/s. Should you fly your plane upwind on the first leg and downwind on the trip back, or across the wind flying east and then west? Optimize your chances by calculating the round-trip time for both routes using your knowledge of vectors and relative velocities. With this pre-race calculation, you can determine the best route and have a major advantage over the competition!

Picture the Problem Let $\vec{\boldsymbol{v}}_{\text{pg}}$ be the velocity of the plane relative to the ground; $\vec{\boldsymbol{v}}_{\text{ag}}$ be the velocity of the air relative to the ground; and $\vec{\boldsymbol{v}}_{\text{pa}}$ the velocity of the plane relative to the air. Then, $\vec{\boldsymbol{v}}_{\text{pg}} = \vec{\boldsymbol{v}}_{\text{pa}} + \vec{\boldsymbol{v}}_{\text{ag}}$. The wind will affect the flight times differently along these two paths.



The speed of the plane, relative to the ground, on its eastbound leg is equal to its speed on its westbound leg. Using the diagram, express the speed of the plane relative to the ground for both directions:

$$v_{pg} = \sqrt{v_{pa}^2 - v_{ag}^2}$$

Substitute numerical values and evaluate v_{pg}:

$$v_{pg} = \sqrt{(15\ \text{m/s})^2 - (5.0\ \text{m/s})^2} = 14.1\ \text{m/s}$$

Express the time for the east-west roundtrip in terms of the distances and velocities for the two legs:

$$t_{\text{roundtrip,EW}} = t_{\text{eastbound}} + t_{\text{westbound}} = \frac{\text{radius of the circle}}{v_{\text{pg,eastbound}}} + \frac{\text{radius of the circle}}{v_{\text{pg,westbound}}}$$

Substitute numerical values and evaluate $t_{\text{roundtrip,EW}}$:

$$t_{\text{roundtrip,EW}} = \frac{2\times 1.0\ \text{km}}{14.1\ \text{m/s}} = 142\ \text{s}$$

Use the distances and speeds for the two legs to express the time for the north-south roundtrip:

$$t_{\text{roundtrip,NS}} = t_{\text{northbound}} + t_{\text{southbound}} = \frac{\text{radius of the circle}}{v_{\text{pg,northbound}}} + \frac{\text{radius of the circle}}{v_{\text{pg,southbound}}}$$

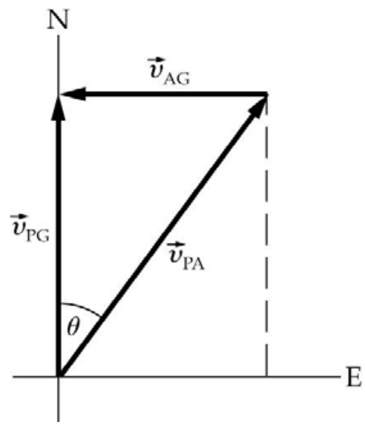
Substitute numerical values and evaluate $t_{\text{roundtrip,NS}}$:

$$t_{\text{roundtrip,NS}} = \frac{1.0\ \text{km}}{(15\ \text{m/s}) - (5.0\ \text{m/s})} + \frac{1.0\ \text{km}}{(15\ \text{m/s}) + (5.0\ \text{m/s})} = 150\ \text{s}$$

Because $t_{\text{roundtrip,EW}} < t_{\text{roundtrip,NS}}$, you should fly your plane across the wind.

60 • You are piloting a small plane that can maintain an air speed of 150 kt (knots, or nautical miles per hour) and you want to fly due north (azimuth = 000º) relative to the ground. (*a*) If a wind of 30 kt is blowing from the east (azimuth = 090º), calculate the heading (azimuth) you must ask your co-pilot to maintain. (*b*) At that heading, what will be your groundspeed?

Picture the Problem This is a relative velocity problem. The given quantities are the direction of the velocity of the plane relative to the ground and the velocity (magnitude and direction) of the air relative to the ground. Asked for is the direction of the velocity of the air relative to the ground. Using $\vec{v}_{PG} = \vec{v}_{PA} + \vec{v}_{AG}$, draw a vector addition diagram and solve for the unknown quantities.



(*a*) Referring to the diagram, relate the heading you must take to the wind speed and the speed of your plane relative to the air:

$$\theta = \sin^{-1}\left(\frac{v_{AG}}{v_{PA}}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left(\frac{30\text{ kts}}{150\text{ kts}}\right) = 11.5°$$

Because this is also the angle of the plane's heading clockwise from north, it is also its azimuth or the required true heading:

$$\text{Az} = (011.5°) = \boxed{(012°)}$$

(*b*) Referring to the diagram, relate your heading to your plane's speeds relative to the ground and relative to the air:

$$\cos\theta = \frac{v_{PG}}{v_{PA}}$$

Solve for the speed of your plane relative to the ground to obtain:

$$v_{PG} = v_{PA}\cos\theta$$

Substitute numerical values and evaluate v_{PG}:

$$v_{PG} = (150\text{ kt})\cos 11.5° = 147\text{ kt}$$
$$= \boxed{1.5\times10^{2}\text{ kt}}$$

61 •• **[SSM]** Car A is traveling east at 20 m/s toward an intersection. As car A crosses the intersection, car B starts from rest 40 m north of the intersection and moves south, steadily gaining speed at 2.0 m/s^2. Six seconds after A crosses the intersection find (*a*) the position of B relative to A, (*b*) the velocity of B relative to A, and (*c*) the acceleration of B relative to A. (*Hint: Let the unit vectors* $\hat{\boldsymbol{i}}$ *and* $\hat{\boldsymbol{j}}$ *be toward the east and north, respectively, and express your answers using* $\hat{\boldsymbol{i}}$ *and* $\hat{\boldsymbol{j}}$.)

Picture the Problem The position of B relative to A is the vector from A to B; that is,

$$\vec{r}_{BA} = \vec{r}_B - \vec{r}_A$$

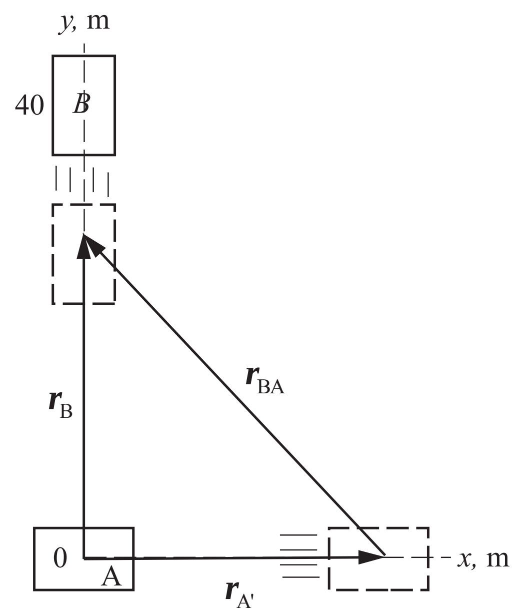
The velocity of B relative to A is

$$\vec{v}_{BA} = d\vec{r}_{BA}/dt$$

and the acceleration of B relative to A is

$$\vec{a}_{BA} = d\vec{v}_{BA}/dt$$

Choose a coordinate system with the origin at the intersection, the $+x$ direction to the east, and the $+y$ direction to the north.



(*a*) Find $\vec{r}_B$ and $\vec{r}_A$:

$$\vec{r}_B = \left[40\text{ m} - \tfrac{1}{2}\left(2.0\text{ m/s}^2\right)t^2\right]\hat{j}$$

and

$$\vec{r}_A = \left[(20\text{ m/s})t\right]\hat{i}$$

Use $\vec{r}_{BA} = \vec{r}_B - \vec{r}_A$ to find $\vec{r}_{BA}$:

$$\vec{r}_{BA} = \left[(-20\text{ m/s})t\right]\hat{i} + \left[40\text{ m} - \tfrac{1}{2}\left(2.0\text{ m/s}^2\right)t^2\right]\hat{j}$$

Evaluate $\vec{r}_{BA}$ at $t = 6.0$ s:

$$\vec{r}_{BA}(6.0\text{ s}) = \left[(-20\text{ m/s})(6.0\text{ s})\right]\hat{i} + \left[40\text{ m} - \tfrac{1}{2}\left(2.0\text{ m/s}^2\right)(6.0\text{ s})^2\right]\hat{j}$$
$$= \boxed{(-1.2\times10^2\text{ m})\,\hat{i} + (4.0\text{ m})\,\hat{j}}$$

(*b*) Find $\vec{v}_{BA} = d\vec{r}_{BA}/dt$:

$$\vec{v}_{BA} = \frac{d\vec{r}_{BA}}{dt} = \frac{d}{dt}\left[\{(-20\text{ m/s})t\}\hat{i} + \left\{40\text{ m} - \tfrac{1}{2}\left(2.0\text{ m/s}^2\right)t^2\right\}\hat{j}\right]$$
$$= (-20\text{ m/s})\,\hat{i} + (-2.0\text{ m/s}^2)\,t\,\hat{j}$$

Evaluate $\vec{v}_{BA}$ at $t = 6.0$ s:

$$\vec{v}_{BA}(6.0\text{ s}) = (-20\text{ m/s})\,\hat{i} + (-2.0\text{ m/s}^2)(6.0\text{ s})\,\hat{j} = \boxed{(-20\text{ m/s})\hat{i} - (12\text{ m/s})\hat{j}}$$

(*c*) Find $\vec{a}_{\mathrm{BA}} = d\vec{v}_{\mathrm{BA}}/dt$:

$$\vec{a}_{\mathrm{BA}} = \frac{d}{dt}\left[(-20\ \mathrm{m/s})\,\hat{i} + (-2.0\ \mathrm{m/s^2})\,t\,\hat{j}\right]$$
$$= \boxed{\left(-2.0\,\mathrm{m/s^2}\right)\hat{j}}$$

Note that $\vec{a}_{\mathrm{BA}}$ is independent of time.

62 •• While walking between gates at an airport, you notice a child running along a moving walkway. Estimating that the child runs at a constant speed of 2.5 m/s relative to the surface of the walkway, you decide to try to determine the speed of the walkway itself. You watch the child run on the entire 21-m walkway in one direction, immediately turn around, and run back to his starting point. The entire trip taking a total elapsed time of 22 s. Given this information, what is the speed of the moving walkway relative to the airport terminal?

Picture the Problem We don't need to know which direction the child ran first, and which he ran second. Because we have the total length of the walkway, the elapsed time for the round trip journey, and the child's walking speed relative to the walkway, we are given sufficient information to determine the moving walkway's speed. The distance covered in the airport is 21 m, and this is covered in a total time of 22 s. When the child walks in the direction of the walkway, his velocity in the airport is the sum of his walking velocity, $\vec{v}_{\mathrm{child}}$, and the walkway velocity, $\vec{v}_{\mathrm{ww}}$. On the return trip, the velocity in the airport is the difference of these two velocities.

Express the total time for the child's run in terms of his running times with and against the moving walkway:

$$\Delta t_{\mathrm{tot}} = \Delta t_{\mathrm{with}} + \Delta t_{\mathrm{against}}$$

In terms of the length L of the walkway and the speeds, relative to the airport, of the child walking with and against the moving walkway:

$$\Delta t_{\mathrm{tot}} = \frac{L}{v_{\mathrm{with}}} + \frac{L}{v_{\mathrm{against}}} \qquad (1)$$

The speeds of the child relative to the airport, then, in each case, are:

$$v_{\mathrm{with}} = \left|\vec{v}_{\mathrm{child}}\right| + \left|\vec{v}_{\mathrm{ww}}\right| = v_{\mathrm{child}} + v_{\mathrm{ww}}$$

and

$$v_{\mathrm{against}} = \left|\vec{v}_{\mathrm{child}}\right| - \left|\vec{v}_{\mathrm{ww}}\right| = v_{\mathrm{child}} - v_{\mathrm{ww}}$$

Substitute for v_{with} and v_{against} in equation (1) to obtain:

$$\Delta t_{\mathrm{tot}} = \frac{L}{v_{\mathrm{child}} + v_{\mathrm{ww}}} + \frac{L}{v_{\mathrm{child}} + v_{\mathrm{ww}}}$$

Solving this equation for v_{ww} yields:

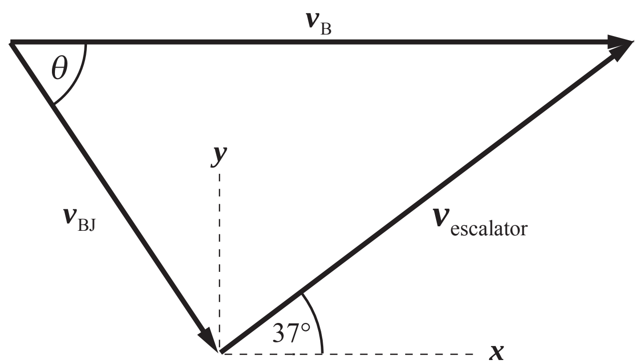
$$v_{\mathrm{ww}} = \sqrt{v_{\mathrm{child}}^2 - \frac{2v_{\mathrm{child}}L}{\Delta t_{\mathrm{tot}}}}$$

Substitute numerical values and evaluate v_{ww}:

$$v_{ww} = \sqrt{(2.5\text{ m/s})^2 - \frac{2(2.5\text{ m/s})(21\text{ m})}{22\text{ s}}} = \boxed{1.2\text{ m/s}}$$

63 •• [SSM] Ben and Jack are shopping in a department store. Ben leaves Jack at the bottom of the escalator and walks east at a speed of 2.4 m/s. Jack then stands on the escalator, which is inclined at an angle of 37° above the horizontal and travels eastward and upward at a speed of 2.0 m/s. (*a*) What is the velocity of Ben relative to Jack? (*b*) At what speed should Jack walk up the escalator so that he is always directly above Ben (until he reaches the top)?

Picture the Problem The velocity of Ben relative to Jack ($\vec{v}_{BJ}$) is the difference between the vectors $\vec{v}_B$ and $\vec{v}_{escalator}$. Choose the coordinate system shown and express these vectors using the unit vectors $\hat{i}$ and $\hat{j}$.



(*a*) The velocity of Ben relative to Jack is given by:

$$\vec{v}_{BJ} = \vec{v}_B - \vec{v}_{escalator}$$

The velocities of the floor walker and the escalator are:

$$\vec{v}_B = (2.4\text{ m/s})\,\hat{i}$$

and

$$\vec{v}_{escalator} = (2.0\text{ m/s})\cos 37°\,\hat{i} + (2.0\text{ m/s})\sin 37°\,\hat{j}$$

Substitute for $\vec{v}_B$ and $\vec{v}_{escalator}$ and simplify to obtain:

$$\begin{aligned}\vec{v}_{BJ} &= (2.4\text{ m/s})\,\hat{i} - \left[(2.0\text{ m/s})\cos 37°\,\hat{i} + (2.0\text{ m/s})\sin 37°\,\hat{j}\right] \\ &= (0.803\text{ m/s})\,\hat{i} - (1.20\text{ m/s})\,\hat{j} \\ &= \boxed{(0.80\text{ m/s})\,\hat{i} - (1.2\text{ m/s})\,\hat{j}}\end{aligned}$$

The magnitude and direction of $\vec{v}_{BJ}$ are given by:

$$\left|\vec{v}_{BJ}\right| = \sqrt{v_{BJ,x}^2 + v_{BJ,y}^2}$$

and

$$\theta = \tan^{-1}\left(\frac{v_{BJ,y}}{v_{BJ,x}}\right)$$

Substitute numerical values and evaluate $\left|\vec{v}_{BJ}\right|$ and θ:

$$\left|\vec{v}_{BJ}\right| = \sqrt{(0.803\text{ m/s})^2 + (-1.20\text{ m/s})^2} = \boxed{1.4\text{ m/s}}$$

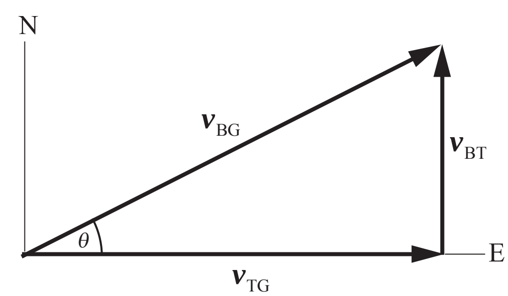
and

$$\theta = \tan^{-1}\left(\frac{-1.20\text{ m/s}}{0.803\text{ m/s}}\right) = -56.2°$$

$$= \boxed{56° \text{ below the horizontal}}$$

64 ••• A juggler traveling in a train on level track throws a ball straight up, relative to the train, with a speed of 4.90 m/s. The train has a velocity of 20.0 m/s due east. As observed by the juggler, (*a*) what is the ball's total time of flight, and (*b*) what is the displacement of the ball during its rise? According to a friend standing on the ground next to the tracks, (*c*) what is the ball's initial speed, (*d*) what is the angle of the launch, and (*e*) what is the displacement of the ball during its rise?

Picture the Problem The vector diagram shows the relationship between the velocity of the ball relative to the train $\vec{v}_{BT}$, the velocity of the train relative to the ground $\vec{v}_{TG}$, and the velocity of the ball relative to the ground $\vec{v}_{BG}$. Choose a coordinate system in which the +*x* direction is to the east and the +*y* direction is to the north.



(*a*) The ball's time-of-flight is twice the time it takes it to reach its maximum height:

$$t_{flight} = 2t_{max\ height} \qquad (1)$$

Use a constant-acceleration equation to relate the ball's speed to its initial speed and the time into its flight:

$$v_y = v_{0y} + a_y t$$

At its maximum height, $v_y = 0$:

$$0 = v_{0y} + a_y t_{\text{max height}}$$

or, because $a_y = -g$,

$$0 = v_{0y} - g t_{\text{max height}}$$

Solving for $t_{\text{max height}}$ yields:

$$t_{\text{max height}} = \frac{v_{0y}}{g}$$

Substitute for $t_{\text{max height}}$ in equation (1) to obtain:

$$t_{\text{flight}} = \frac{2v_{0y}}{g}$$

Substitute numerical values and evaluate t_{flight}:

$$t_{\text{flight}} = \frac{2(4.90\ \text{m/s})}{9.81\ \text{m/s}^2} = \boxed{1.00\ \text{s}}$$

(*b*) The displacement of the ball during its rise is given by:

$$\Delta\vec{\boldsymbol{y}}_{\text{BT}} = \Delta y_{\text{BT}}\hat{\boldsymbol{j}}$$

Use a constant-acceleration equation to relate the displacement of the ball during its ascent to its initial and final speeds:

$$v_x^2 = v_{0x}^2 - 2g\Delta y_{\text{BT}}$$

or, because $v_x = 0$,

$$0 = v_{0x}^2 - 2g\Delta y_{\text{BT}} \Rightarrow \Delta y_{\text{BT}} = \frac{v_{0x}^2}{2g}$$

Substituting for Δy_{BT} gives:

$$\Delta\vec{\boldsymbol{y}}_{\text{BT}} = \frac{v_{0x}^2}{2g}\hat{\boldsymbol{j}}$$

Substitute numerical values and evaluate $\Delta\vec{\boldsymbol{y}}_{\text{BT}}$:

$$\Delta\vec{\boldsymbol{y}}_{\text{BT}} = \frac{(4.90\ \text{m/s})^2}{2(9.81\ \text{m/s}^2)}\hat{\boldsymbol{j}} = \boxed{(1.22\ \text{m})\hat{\boldsymbol{j}}}$$

(*c*) $\vec{\boldsymbol{v}}_{\text{BG}}$ is the sum of $\vec{\boldsymbol{v}}_{\text{BT}}$ and $\vec{\boldsymbol{v}}_{\text{TG}}$:

$$\vec{\boldsymbol{v}}_{\text{BG}} = \vec{\boldsymbol{v}}_{\text{BT}} + \vec{\boldsymbol{v}}_{\text{TG}} \qquad (3)$$

Express $\vec{\boldsymbol{v}}_{\text{BT}}$ and $\vec{\boldsymbol{v}}_{\text{TG}}$ in terms of the unit vectors $\hat{\boldsymbol{i}}$ and $\hat{\boldsymbol{j}}$:

$$\vec{\boldsymbol{v}}_{\text{BT}} = 0\hat{\boldsymbol{i}} + (4.90\ \text{m/s})\hat{\boldsymbol{j}}$$

and

$$\vec{\boldsymbol{v}}_{\text{TG}} = (20.0\ \text{m/s})\hat{\boldsymbol{i}} + 0\hat{\boldsymbol{j}}$$

Substitute for $\vec{\boldsymbol{v}}_{\text{BT}}$ and $\vec{\boldsymbol{v}}_{\text{TG}}$ in equation (1) to obtain:

$$\vec{\boldsymbol{v}}_{\text{BG}} = (20.0\ \text{m/s})\hat{\boldsymbol{i}} + (4.90\ \text{m/s})\hat{\boldsymbol{j}}$$

The magnitude of $\vec{\boldsymbol{v}}_{\text{BG}}$ is given by:

$$v_{\text{BG}} = \sqrt{(20.0\ \text{m/s})^2 + (4.90\ \text{m/s})^2} = \boxed{20.6\ \text{m/s}}$$

(*d*) Referring to the vector diagram, express the angle of the launch θ in terms of v_{BT} and v_{TG}:

$$\theta = \tan^{-1}\left(\frac{v_{BT}}{v_{TG}}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left(\frac{4.90\text{ m/s}}{20.0\text{ m/s}}\right) = \boxed{13.8°}$$

(*e*) When the ball is at its peak it is 20.0 m east and 1.22 m above the friend observing from the ground. Hence its displacement is:

$$\vec{\boldsymbol{d}} = \boxed{(20.0\text{ m})\hat{\boldsymbol{i}} + (1.22\text{ m})\hat{\boldsymbol{j}}}$$

Circular Motion and Centripetal Acceleration

65 • What is the magnitude of the acceleration of the tip of the minute hand of the clock in Problem 38? Express it as a fraction of the magnitude of free-fall acceleration *g*.

Picture the Problem We can use the definition of centripetal acceleration to express a_c in terms of the speed of the tip of the minute hand. We can find the tangential speed of the tip of the minute hand by using the distance it travels each revolution and the time it takes to complete each revolution.

Express the magnitude of the acceleration of the tip of the minute hand of the clock as a function of the length of the hand and the speed of its tip:

$$a_c = \frac{v^2}{R} \qquad (1)$$

Use the distance the minute hand travels every hour to express its speed:

$$v = \frac{2\pi R}{T}$$

Substituting for *v* in equation (1) yields:

$$a_c = \frac{4\pi^2 R}{T^2}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{4\pi^2(0.50\text{ m})}{(3600\text{ s})^2} = 1.52\times10^{-6}\text{ m/s}^2$$

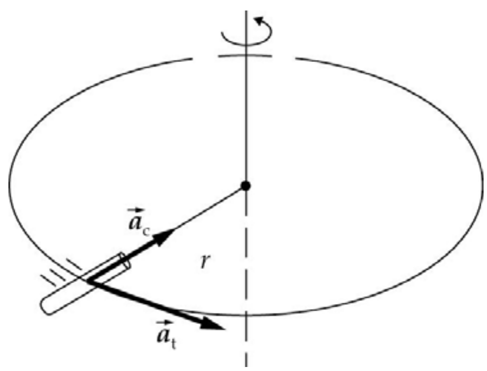
$$= \boxed{1.5\times10^{-6}\text{ m/s}^2}$$

Express the ratio of a_c to *g*:

$$\frac{a_c}{g} = \frac{1.52\times10^{-6}\text{ m/s}^2}{9.81\text{ m/s}^2} = \boxed{1.55\times10^{-7}}$$

66 • You are designing a centrifuge to spins at a rate of 15,000 rev/min. (*a*) Calculate the maximum centripetal acceleration that a test-tube sample held in the centrifuge arm 15 cm from the rotation axis must withstand. (*b*) It takes 1 min, 15 s for the centrifuge to spin up to its maximum rate of revolution from rest. Calculate the *magnitude* of the tangential acceleration of the centrifuge while it is spinning up, assuming that the tangential acceleration is constant.

Picture the Problem The following diagram shows the centripetal and tangential accelerations experienced by the test tube. The tangential acceleration will be zero when the centrifuge reaches its maximum speed. The centripetal acceleration increases as the tangential speed of the centrifuge increases. We can use the definition of centripetal acceleration to express a_c in terms of the speed of the test tube. We can find the tangential speed of the test tube by using the distance it travels each revolution and the time it takes to complete each revolution. The tangential acceleration can be found from the change in the tangential speed as the centrifuge is spinning up.



(*a*) Express the maximum centripetal acceleration of the centrifuge arm as a function of the length of its arm and the speed of the test tube:

$$a_{c,\max} = \frac{v^2}{R} \quad (1)$$

Use the distance the test tube travels every revolution to express its speed:

$$v = \frac{2\pi R}{T}$$

Substituting for v in equation (1) yields:

$$a_{c,\max} = \frac{4\pi^2 R}{T^2}$$

Substitute numerical values and evaluate a_c:

$$a_{c,\max} = \frac{4\pi^2(0.15\,\text{m})}{\left(\frac{1\,\text{min}}{15000\,\text{rev}} \times \frac{60\,\text{s}}{\text{min}}\right)^2} = \boxed{3.7\times10^5\ \text{m/s}^2}$$

(*b*) Express the tangential acceleration in terms of the difference between the final and initial tangential speeds:

$$a_t = \frac{v_f - v_i}{\Delta t} = \frac{\frac{2\pi R}{T} - 0}{\Delta t} = \frac{2\pi R}{T\Delta t}$$

Substitute numerical values and evaluate a_T:

$$a_t = \frac{2\pi(0.15\,\text{m})}{\left(\frac{1\,\text{min}}{15000\,\text{rev}} \times \frac{60\,\text{s}}{\text{min}}\right)(75\,\text{s})} = \boxed{3.1\,\text{m/s}^2}$$

67 ••• [SSM] Earth rotates on its axis once every 24 hours, so that objects on its surface that are stationary with respect to the surface execute uniform circular motion about the axis with a period of 24 hours. Consider only the effect of this rotation on the person on the surface. (Ignore Earth's orbital motion about the Sun.) (*a*) What is the speed and what is the magnitude of the acceleration of a person standing on the equator? (Express the magnitude of this acceleration as a percentage of *g*.) (*b*) What is the direction of the acceleration vector? (*c*) What is the speed and what is the magnitude of the centripetal acceleration of a person standing on the surface at 35°N latitude? (*d*) What is the angle between the direction of the acceleration of the person at 35°N latitude and the direction of the acceleration of the person at the equator if both persons are at the same longitude?

Picture the Problem The radius of Earth is 6370 km. Thus at the equator, a person undergoes circular motion with radius equal to Earth's radius, and a period of 24 h = 86400 s. At 35° N latitude, the person undergoes circular motion having radius $r\cos 35^\circ$ = 5220 km, and the same period.

The centripetal acceleration experienced by a person traveling with a speed v in a circular path of radius r is given by:

$$a = \frac{v^2}{r} \qquad (1)$$

The speed of the person is the distance the person travels in one revolution divided by the elapsed time (the period T):

$$v = \frac{2\pi r}{T}$$

Substitute for v in equation (1) to obtain:

$$a = \frac{\left(\frac{2\pi r}{T}\right)^2}{r} = \frac{4\pi^2 r}{T^2}$$

(*a*) Substitute numerical values and evaluate v for the person at the equator:

$$v = \frac{2\pi(6370\,\text{km})}{86400\,\text{s}} = \boxed{463\,\text{m/s}}$$

Substitute numerical values and evaluate a for the person at the equator:

$$a = \frac{4\pi^2 (6370\ \text{km})}{(86400\ \text{s})^2} = 3.369 \times 10^{-2}\ \text{m/s}^2$$
$$= \boxed{3.37\ \text{cm/s}^2}$$

The ratio of a to g is:

$$\frac{a}{g} = \frac{3.369 \times 10^{-2}\ \text{m/s}^2}{9.81\ \text{m/s}^2} = \boxed{0.343\%}$$

(*b*) The acceleration vector points directly at the center of Earth.

(*c*) Substitute numerical values and evaluate v for the person at 35°N latitude:

$$v = \frac{2\pi (5220\ \text{km})}{86400\ \text{s}} = \boxed{380\ \text{m/s}}$$

Substitute numerical values and evaluate v for the person at 35°N latitude:

$$a = \frac{4\pi^2 (5220\ \text{km})}{(86400\ \text{s})^2} = \boxed{2.76\ \text{cm/s}^2}$$

(*d*) The plane of the person's path is parallel to the plane of the equator – the acceleration vector is in the plane – so that it is perpendicular to Earth's axis, pointing at the center of the person's revolution, rather than the center of Earth.

68 •• Determine the acceleration of the Moon toward Earth, using values for its mean distance and orbital period from the Terrestrial and Astronomical Data table in this book. Assume a circular orbit. Express the acceleration as a fraction of the magnitude of free-fall acceleration g.

Picture the Problem We can relate the acceleration of the Moon toward Earth to its orbital speed and distance from Earth. Its orbital speed can be expressed in terms of its distance from Earth and its orbital period. From the Terrestrial and Astronomical Data table, we find that the sidereal period of the Moon is 27.3 d and that its mean distance from Earth is 3.84×10^8 m.

Express the centripetal acceleration of the Moon:

$$a_c = \frac{v^2}{r} \qquad (1)$$

Express the orbital speed of the Moon:

$$v = \frac{2\pi r}{T}$$

Substituting for v in equation (1) yields:

$$a_c = \frac{4\pi^2 r}{T^2}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{4\pi^2\left(3.84\times10^8\ \text{m}\right)}{\left(27.3\ \text{d}\times\frac{24\ \text{h}}{\text{d}}\times\frac{3600\ \text{s}}{\text{h}}\right)^2} = 2.72\times10^{-3}\ \text{m/s}^2 = \boxed{2.78\times10^{-4}\ g}$$

Remarks: Note that $\frac{\mathbf{a_c}}{\mathbf{g}} = \frac{\textbf{radius of Earth}}{\textbf{distance from Earth to Moon}}$ **(a_c is just the acceleration due to Earth's gravity evaluated at the moon's position). This is Newton's famous ″falling apple″ observation.**

69 •• (*a*) What are the period and speed of the motion of a person on a carousel if the person has an acceleration magnitude of 0.80 m/s^2 when she is standing 4.0 m from the axis? (*b*) What are her acceleration magnitude and speed if she then moves in to a distance of 2.0 m from the carousel center and the carousel keeps rotating with the same period?

Picture the Problem The person riding on this carousel experiences a centripetal acceleration due to the fact that her velocity is continuously changing. Use the expression for centripetal acceleration to relate her speed to her centripetal acceleration and the relationship between distance, speed, and time to find the period of her motion.

In general, the acceleration and period of any object moving in a circular path at constant speed are given by:

$$a_c = \frac{v^2}{r} \qquad (1)$$

and

$$T = \frac{2\pi r}{v} \qquad (2)$$

Solving equation (1) for v yields:

$$v = \sqrt{a_c r} \qquad (3)$$

Substituting for v in equation (2) yields:

$$T = \frac{2\pi r}{\sqrt{a_c r}} = 2\pi\sqrt{\frac{r}{a_c}} \qquad (4)$$

(*a*) Substitute numerical values in equation (3) and evaluate v for a person standing 4.0 m from the axis:

$$v = \sqrt{\left(0.80\ \text{m/s}^2\right)\left(4.0\ \text{m}\right)} = 1.79\ \text{m/s} = \boxed{1.8\ \text{m/s}}$$

Substitute numerical values in equation (4) and evaluate T for a person standing 4.0 m from the axis:

$$T = 2\pi\sqrt{\frac{4.0\ \text{m}}{0.80\ \text{m/s}^2}} = 14.05\ \text{s} = \boxed{14\ \text{s}}$$

(*b*) Solve equation (2) for v to obtain:

$$v = \frac{2\pi r}{T}$$

For a person standing 2.0 m from the axis:

$$v = \frac{2\pi(2.0\ \text{m})}{14.05\ \text{s}} = 0.894\ \text{m/s} = \boxed{0.89\ \text{m/s}}$$

From equation (1) we have, for her acceleration:

$$a_c = \frac{(0.894\ \text{m/s})^2}{2.0\ \text{m}} = \boxed{0.40\ \text{m/s}^2}$$

70 ••• Pulsars are neutron stars that emit X rays and other radiation in such a way that we on Earth receive pulses of radiation from the pulsars at regular intervals equal to the period that they rotate. Some of these pulsars rotate with periods as short as 1 ms! The Crab Pulsar, located inside the Crab Nebula in the constellation Orion, has a period currently of length 33.085 ms. It is estimated to have an equatorial radius of 15 km, which is an average radius for a neutron star. (*a*) What is the value of the centripetal acceleration of an object on the surface and at the equator of the pulsar? (*b*) Many pulsars are observed to have periods that lengthen slightly with time, a phenomenon called "spin down." The rate of slowing of the Crab Pulsar is 3.5×10^{-13} s per second, which implies that if this rate remains constant, the Crab Pulsar will stop spinning in 9.5×10^{10} s (about 3000 years). What is the tangential acceleration of an object on the equator of this neutron star?

Picture the Problem We need to know the speed of a point on the equator where the object sits. The circular path that the object at the equator undergoes has a radius equal to that of the star, and therefore is simply the equatorial circumference – and is traversed in a time interval of one period, 33.085 ms. In (*b*) we need only consider the change in speed of an object on the surface over the course of this time period.

(*a*) The centripetal acceleration of the object is given by:

$$a_c = \frac{v^2}{r} \qquad (1)$$

The speed of the object is equal to related to the radius of its path and the period of its motion:

$$v = \frac{2\pi r}{T}$$

Substituting for v in equation (1) yields:

$$a_c = \frac{\left(\frac{2\pi r}{T}\right)^2}{r} = \frac{4\pi^2 r}{T^2}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{4\pi^2(15\ \text{km})}{(33.085\ \text{ms})^2} = \boxed{5.4\times10^8\ \text{m/s}^2}$$

(*b*) The tangential acceleration of an object on the equator of the neutron star is given by:

$$a_{\mathrm{t}}=\frac{\Delta v_{\mathrm{t}}}{\Delta t_{\text{spin down}}}=\frac{v_{\text{t, final}}-v_{\text{t, initial}}}{\Delta t_{\text{spin down}}}$$

Because $\boldsymbol{v}_{\text{r,final}}=0$:

$$a_{\mathrm{t}}=\frac{-v_{\text{t, initial}}}{\Delta t_{\text{spin down}}}$$

We can obtain the initial speed of the object from equation (1):

$$v_{\text{t, initial}}=\frac{2\pi r}{T}$$

Substitute for $\boldsymbol{v}_{\text{r,final}}=0$ to obtain:

$$a_{\mathrm{t}}=\frac{-\dfrac{2\pi r}{T}}{\Delta t_{\text{spin down}}}=-\frac{2\pi r}{\Delta t_{\text{spin down}}T}$$

Substitute numerical values and evaluate $\boldsymbol{a}_{\mathrm{t}}$:

$$a_{\mathrm{t}}=-\frac{2\pi(15\text{ km})}{(9.5\times10^{10}\text{ s})(33.085\times10^{-3}\text{ s})}=\boxed{-3.0\times10^{-5}\text{ m/s}^2}$$

71 ••• Human blood contains plasma, platelets and blood cells. To separate the plasma from other components, centrifugation is used. Effective centrifugation requires subjecting blood to an acceleration of 2000*g* or more. In this situation, assume that blood is contained in test tubes that are 15 cm long and are full of blood. These tubes ride in the centrifuge tilted at an angle of 45.0° above the horizontal (See Figure 3-34.) (*a*) What is the distance of a sample of blood from the rotation axis of a centrifuge rotating at 3500 rpm, if it has an acceleration of 2000*g*? (*b*) If the blood at the center of the tubes revolves around the rotation axis at the radius calculated in Part (*a*), calculate the centripetal accelerations experienced by the blood at each end of the test tube. Express all accelerations as multiples of *g*.

Picture the Problem The equations that describe the centripetal acceleration and speed of objects moving in circular paths at constant speed can be used to find the distance of the sample of blood from the rotation axis as well as the accelerations experienced by the blood at each end of the test tube under the conditions described in the problem statement.

(*a*) The centripetal acceleration of the blood sample is given by:

$$a_{\mathrm{c}}=\frac{v^2}{r}$$

The speed of the blood's revolution is given by:

$$v=\frac{2\pi r}{T}=2\pi rf$$

where *f* is the frequency of revolution.

Substitute for v in the expression for a_c to obtain:

$$a_c = \frac{(2\pi rf)^2}{r} = 4\pi^2 f^2 r \qquad (1)$$

Solving for r yields:

$$r = \frac{a_c}{4\pi^2 f^2}$$

or, because $a_c = g$,

$$r = \frac{2000g}{4\pi^2 f^2}$$

Substitute numerical values and evaluate r:

$$r = \frac{2000(9.81\ \text{m/s}^2)}{4\pi^2\left(3500\ \frac{\text{rev}}{\text{min}} \times \frac{1\ \text{min}}{60\ \text{s}}\right)^2} = 0.146\ \text{m}$$

$$= \boxed{15\ \text{cm}}$$

(b) The center of the tube undergoes uniform circular motion with a radius of 15cm. Because the tubes are tilted at a 45 degree angle, the top surface of the blood is undergoing uniform circular motion with a radius of:

$$r_{\text{top}} = 14.6\ \text{cm} - (7.5\ \text{cm})\cos 45° = 9.30\ \text{cm}$$

The bottom surface is moving in a circle of radius:

$$r_{\text{bottom}} = 14.6\ \text{cm} + (7.5\ \text{cm})\cos 45° = 19.90\ \text{cm}$$

The range of accelerations can be found from equation (1):

$$a_c = 4\pi^2 f^2 r$$

The minimum acceleration corresponds to r_{top}:

$$a_{\min} = 4\pi^2 f^2 r_{\text{top}}$$

Substitute numerical values and evaluate $a_{\min}$:

$$a_{\min} = 4\pi^2\left(3500\ \frac{\text{rev}}{\text{min}} \times \frac{1\ \text{min}}{60\ \text{s}}\right)^2 (9.30\ \text{cm}) = 1.249\times10^4\ \text{m/s}^2 \approx \boxed{1300g}$$

The maximum acceleration corresponds to r_{bottom}:

$$a_{\max} = 4\pi^2 f^2 r_{\text{bottom}}$$

Substitute numerical values and evaluate a_{max}:

$$a_{max} = 4\pi^2\left(3500\,\frac{\text{rev}}{\text{min}}\times\frac{1\,\text{min}}{60\,\text{s}}\right)^2(19.90\,\text{cm}) = 2.673\times10^4\ \text{m/s}^2 \approx \boxed{2700g}$$

The range of accelerations is 1300*g* to 2700*g*.

Projectile Motion and Projectile Range

72 • While trying out for the position of pitcher on your high school baseball team, you throw a fastball at 87 mi/h toward home plate, which is 18.4 m away. How far does the ball drop due to effects of gravity by the time it reaches home plate? (Ignore any effects due to air resistance.)

Picture the Problem Neglecting air resistance, the accelerations of the ball are constant and the horizontal and vertical motions of the ball are independent of each other. We can use the horizontal motion to determine the time-of-flight and then use this information to determine the distance the ball drops. Choose a coordinate system in which the origin is at the point of release of the ball, downward is the positive y direction, and the horizontal direction is the positive x direction.

Express the vertical displacement of the ball:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $a_y = g$,

$$\Delta y = \tfrac{1}{2}g(\Delta t)^2 \qquad (1)$$

Use $v_x = \Delta x/\Delta t$ to express the time of flight:

$$\Delta t = \frac{\Delta x}{v_x}$$

Substitute for Δt in equation (1) to obtain:

$$\Delta y = \tfrac{1}{2}g\left(\frac{\Delta x}{v_x}\right)^2 = \frac{g(\Delta x)^2}{2(v_x)^2}$$

Substitute numerical values and evaluate Δy:

$$\Delta y = \frac{\left(9.81\,\frac{\text{m}}{\text{s}^2}\right)(18.4\,\text{m})^2}{2\left(87\,\frac{\text{mi}}{\text{h}}\cdot\frac{0.4470\,\frac{\text{m}}{\text{s}}}{1\,\frac{\text{mi}}{\text{h}}}\right)^2} = \boxed{1.1\,\text{m}}$$

73 • A projectile is launched with speed v_0 at an angle of θ_0 above the horizontal. Find an expression for the maximum height it reaches above its starting point in terms of v_0, θ_0, and g. (Ignore any effects due to air resistance.)

Picture the Problem In the absence of air resistance, the maximum height achieved by a projectile depends on the vertical component of its initial velocity.

Use a constant-acceleration equation to relate the displacement of a projectile to its initial and final speeds and its acceleration:

$$v_y^2 = v_{0y}^2 + 2a_y\Delta y \Rightarrow \Delta y = \frac{v_y^2 - v_{0y}^2}{2a_y}$$

Because $v_y = 0$ and $a_y = -g$:

$$\Delta y = \frac{v_{0y}^2}{2g}$$

The vertical component of the projectile's initial velocity is:

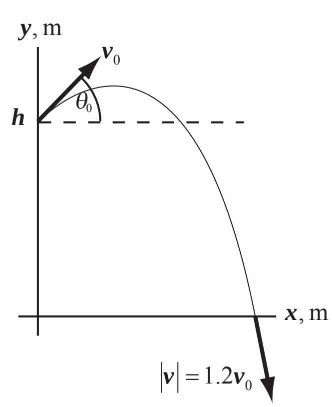
$$v_{0y} = v_0 \sin\theta_0$$

Setting $\Delta y = h$ and substituting for v_{0y} yields:

$$h = \boxed{\frac{(v_0 \sin\theta_0)^2}{2g}}$$

74 •• A cannonball is fired with initial speed v_0 at an angle 30º above the horizontal from a height of 40 m above the ground. The projectile strikes the ground with a speed of $1.2v_0$. Find v_0. (Ignore any effects due to air resistance.)

Picture the Problem Choose the coordinate system shown to the right. Because, in the absence of air resistance, the horizontal and vertical speeds are independent of each other, we can use constant-acceleration equations to relate the impact speed of the projectile to its components.



The horizontal and vertical velocity components are:

$$v_{0x} = v_x = v_0 \cos\theta_0$$

and

$$v_{0y} = v_0 \sin\theta_0$$

Using a constant-acceleration equation, relate the vertical component of the velocity to the vertical displacement of the projectile:

$$v_y^2 = v_{0y}^2 + 2a_y\Delta y$$

or, because $a_y = -g$ and $\Delta y = -h$,

$$v_y^2 = (v_0 \sin\theta_0)^2 + 2gh$$

Express the relationship between the magnitude of a velocity vector and its components, substitute for the components, and simplify to obtain:

$$\begin{aligned} v^2 &= v_x^2 + v_y^2 = (v_0 \cos\theta_0)^2 + v_y^2 \\ &= v_0^2(\sin^2\theta_0 + \cos^2\theta_0) + 2gh \\ &= v_0^2 + 2gh \end{aligned}$$

Substituting for v and solving for v_0 gives:

$$(1.2v_0)^2 = v_0^2 + 2gh \Rightarrow v_0 = \sqrt{\frac{2gh}{0.44}}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{\frac{2(9.81\,\text{m/s}^2)(40\,\text{m})}{0.44}} = \boxed{42\,\text{m/s}}$$

Remarks: Note that v is independent of θ_0. This will be more obvious once conservation of energy has been studied.

75 •• In Figure 3.35, what is the minimum initial speed of the dart if it is to hit the monkey before the monkey hits the ground, which is 11.2 m below the initial position of the monkey, if x is 50 m and h = 10 m? (Ignore any effects due to air resistance.)

Picture the Problem Example 3-12 shows that the dart will hit the monkey unless the dart hits the ground before reaching the monkey's line of fall. What initial speed does the dart need in order to just reach the monkey's line of fall? First, we will calculate the fall time of the monkey, and then we will calculate the horizontal component of the dart's velocity.

Relate the horizontal speed of the dart to its launch angle and initial velocity v_0:

$$v_x = v_0 \cos\theta \Rightarrow v_0 = \frac{v_x}{\cos\theta}$$

Use the definition of v_x and the fact that, in the absence of air resistance, it is constant to obtain:

$$v_x = \frac{\Delta x}{\Delta t}$$

Substituting in the expression for v_0 yields:

$$v_0 = \frac{\Delta x}{(\cos\theta)\Delta t} \qquad (1)$$

Using a constant-acceleration equation, relate the monkey's fall distance to the fall time:

$$\Delta h = \tfrac{1}{2} g (\Delta t)^2 \Rightarrow \Delta t = \sqrt{\frac{2\Delta h}{g}}$$

Substituting for Δt in equation (1) yields:

$$v_0 = \frac{\Delta x}{\cos\theta}\sqrt{\frac{g}{2\Delta h}} \qquad (2)$$

Let θ be the angle the barrel of the dart gun makes with the horizontal. Then:

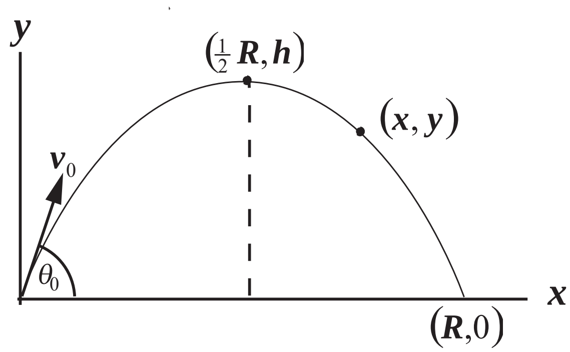
$$\theta = \tan^{-1}\left(\frac{10\,\text{m}}{50\,\text{m}}\right) = 11.3°$$

Substitute numerical values in equation (2) and evaluate v_0:

$$v_0 = \frac{50\text{ m}}{\cos 11.3°}\sqrt{\frac{9.81\,\text{m/s}^2}{2(11.2\,\text{m})}} = \boxed{34\text{ m/s}}$$

76 •• A projectile is launched from ground level with an initial speed of 53 m/s. Find the launch angle (the angle the initial velocity vector is above the horizontal) such that the maximum height of the projectile is equal to its horizontal range. (Ignore any effects due to air resistance.)

Picture the Problem Choose the coordinate system shown in the figure to the right. In the absence of air resistance, the projectile experiences constant acceleration in both the x and y directions. We can use the constant-acceleration equations to express the x and y coordinates of the projectile along its trajectory as functions of time. The elimination of the parameter t will yield an expression for y as a function of x that we can evaluate at (R, 0) and (R/2, h). Solving these equations simultaneously will yield an expression for θ.



Express the position coordinates of the projectile along its flight path in terms of the parameter t:

$$x = (v_0\cos\theta)t$$

and

$$y = (v_0\sin\theta)t - \tfrac{1}{2}gt^2$$

Eliminate t from these equations to obtain:

$$y = (\tan\theta)x - \frac{g}{2v_0^2\cos^2\theta}x^2 \qquad (1)$$

Evaluate equation (1) at $(R, 0)$ to obtain:

$$R = \frac{2v_0^2 \sin\theta \cos\theta}{g}$$

Evaluate equation (1) at $(R/2, h)$ to obtain:

$$h = \frac{(v_0 \sin\theta)^2}{2g}$$

Equating R and h yields:

$$\frac{2v_0^2 \sin\theta \cos\theta}{g} = \frac{(v_0 \sin\theta)^2}{2g}$$

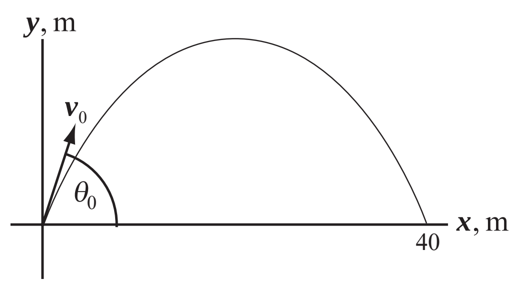
Solving for θ gives:

$$\theta = \tan^{-1}(4) = \boxed{76°}$$

Note that this result is independent of v_0.

77 •• [SSM] A ball launched from ground level lands 2.44 s later 40.0-m away from the launch point. Find the magnitude of the initial velocity vector and the angle it is above the horizontal. (Ignore any effects due to air resistance.)

Picture the Problem In the absence of air resistance, the motion of the ball is uniformly accelerated and its horizontal and vertical motions are independent of each other. Choose the coordinate system shown in the figure to the right and use constant-acceleration equations to relate the x and y components of the ball's initial velocity.



Express θ_0 in terms of v_{0x} and v_{0y}:

$$\theta_0 = \tan^{-1}\left(\frac{v_{0y}}{v_{0x}}\right) \quad (1)$$

Use the Pythagorean relationship between the velocity and its components to express v_0:

$$v_0 = \sqrt{v_{0x}^2 + v_{0y}^2} \quad (2)$$

Using a constant-acceleration equation, express the vertical speed of the projectile as a function of its initial upward speed and time into the flight:

$$v_y = v_{0y} + a_y t \Rightarrow v_{0y} = v_y - a_y t$$

Because $v_y = 0$ halfway through the flight (at maximum elevation) and $a_y = -g$:

$$v_{0y} = g t_{\text{max elevation}}$$

Substitute numerical values and evaluate v_{0y}:

$$v_{0y}=(9.81\text{ m/s}^2)(1.22\text{ s})=11.97\text{ m/s}$$

Because there is no acceleration in the horizontal direction, v_{0x} can be found from:

$$v_{0x}=\frac{\Delta x}{\Delta t}=\frac{40.0\text{ m}}{2.44\text{ s}}=16.39\text{ m/s}$$

Substitute for v_{0x} and v_{0y} in equation (2) and evaluate v_0:

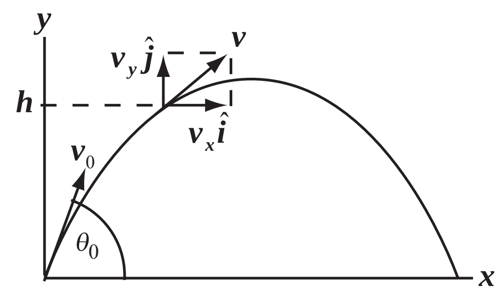
$$v_0=\sqrt{(16.39\text{ m/s})^2+(11.97\text{ m/s})^2}=\boxed{20.3\text{ m/s}}$$

Substitute for v_{0x} and v_{0y} in equation (1) and evaluate θ_0 :

$$\theta_0=\tan^{-1}\left(\frac{11.97\text{ m/s}}{16.39\text{ m/s}}\right)=\boxed{36.1°}$$

78 •• Consider a ball that is launched from ground level with initial speed v_0 at an angle θ_0 above the horizontal. If we consider its speed to be v at height h above the ground, show that for a given value of h, v is independent of θ_0. (Ignore any effects due to air resistance.)

Picture the Problem In the absence of friction, the acceleration of the ball is constant and we can use the constant-acceleration equations to describe its motion. The figure shows the launch conditions and an appropriate coordinate system. The speeds v, v_x, and v_y are related by the Pythagorean Theorem.



The squares of the vertical and horizontal components of the object's velocity are:

$$v_y^2=v_0^2\sin^2\theta_0-2gh$$

and

$$v_x^2=v_0^2\cos^2\theta_0$$

The relationship between these variables is:

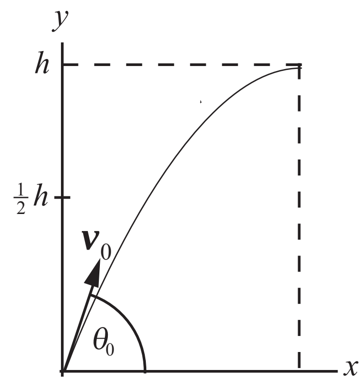
$$v^2=v_x^2+v_y^2$$

Substitute for v_x and v_y and simplify to obtain:

$$\begin{aligned}v^2&=v_0^2\cos^2\theta_0+v_0^2\sin^2\theta_0-2gh\\&=v_0^2(\cos^2\theta_0+\sin^2\theta_0)-2gh\\&=\boxed{v_0^2-2gh}\end{aligned}$$

79 ••• At $\frac{1}{2}$ of its maximum height, the speed of a projectile is $\frac{3}{4}$ of its initial speed. What was its launch angle? (Ignore any effects due to air resistance.)

Picture the Problem In the absence of air resistance, the projectile experiences constant acceleration during its flight and we can use constant-acceleration equations to relate the speeds at half the maximum height and at the maximum height to the launch angle θ_0 of the projectile.



The angle θ the initial velocity makes with the horizontal is related to the initial velocity components:

$$\theta_0 = \tan^{-1}\left(\frac{v_{0y}}{v_{0x}}\right) \quad (1)$$

Using a constant-acceleration equation, relate the vertical component of the speed to the projectile to its acceleration and displacement:

$$v_y^2 = v_{0y}^2 + 2a\Delta y \quad (2)$$

When the projectile is at the top of its trajectory $\Delta y = h$ and $v_y = 0$. Hence:

$$0 = v_{0y}^2 - 2gh \Rightarrow v_{0y}^2 = 2gh$$

When $\Delta y = \frac{1}{2}h$ equation (2) becomes:

$$v_y^2 = v_{0y}^2 - gh \quad (3)$$

Substituting for v_{0y}^2 and simplifying yields:

$$v_y^2 = 2gh - gh = gh$$

We are given that $v = \frac{3}{4}v_0$ when $\Delta y = \frac{1}{2}h$. Square both sides of $v = \frac{3}{4}v_0$ and express this using the components of the velocity.

$$v_{0x}^2 + v_y^2 = \left(\tfrac{3}{4}\right)^2\left(v_{0x}^2 + v_{0y}^2\right) \quad (4)$$

where we have used v_{0x} for v_x because the x component of the velocity remains constant.

Solving equation (2) for v_{0y}^2 gives:

Substitute for v_{0y}^2 in equation (3) to obtain:

$$v_y^2 = 2gh - gh = gh$$

Substituting for v_y^2 and v_{0y}^2 in equation (4) yields:

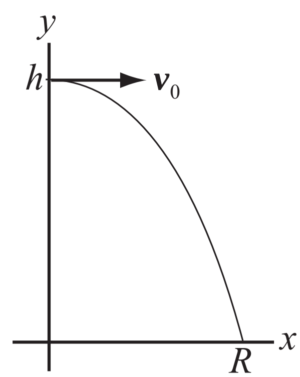
$$v_{0x}^2 + gh = \tfrac{9}{16}\left(v_{0x}^2 + 2gh\right) \Rightarrow v_{0x}^2 = \tfrac{2}{7}gh$$

Finally, substituting for v_{0y} and v_{0x} in equation (1) and simplifying gives:

$$\theta_0 = \tan^{-1}\left(\frac{\sqrt{2gh}}{\sqrt{\frac{2}{7}gh}}\right) = \tan^{-1}\left(\sqrt{7}\right) = \boxed{69.3°}$$

80 •• A cargo plane is flying horizontally at an altitude of 12 km with a speed of 900 km/h when a large crate falls out of the rear-loading ramp. (Ignore any effects due to air resistance.) (*a*) How long does it take the crate to hit the ground? (*b*) How far horizontally is the crate from the point where it fell off when it hits the ground? (*c*) How far is the crate from the aircraft when the crate hits the ground, assuming that the plane continues to fly with the same velocity?

Picture the Problem The horizontal speed of the crate, in the absence of air resistance, is constant and equal to the speed of the cargo plane. Choose a coordinate system in which the direction the plane is moving is the positive x direction and downward is the positive y direction and apply the constant-acceleration equations to describe the crate's displacements at any time during its flight.



(*a*) Using a constant-acceleration equation, relate the vertical displacement of the crate Δy to the time of fall Δt:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}g(\Delta t)^2$$

or, because $v_{0y} = 0$ and $\Delta y = h$,

$$h = \tfrac{1}{2}g(\Delta t)^2 \Rightarrow \Delta t = \sqrt{\frac{2h}{g}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \sqrt{\frac{2(12\times10^3\ \text{m})}{9.81\,\text{m/s}^2}} = 49.46\,\text{s} = \boxed{49\,\text{s}}$$

(*b*) The horizontal distance traveled in time Δt is:

$$R = \Delta x = v_{0x}\Delta t$$

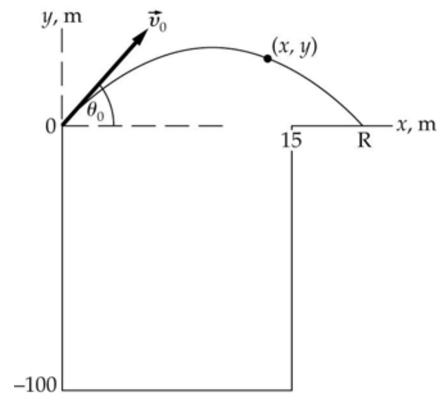
Substitute numerical values and evaluate R:

$$R = (900\,\text{km/h})\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)(49.46\,\text{s}) = \boxed{12\,\text{km}}$$

(*c*) Because the velocity of the plane is constant, it will be directly over the crate when it hits the ground; that is, the distance to the aircraft will be the elevation of the aircraft. Therefore $\Delta y = \boxed{12\,\text{km}}$.

81 •• [SSM] Wile E. Coyote (*Carnivorous hungribilous*) is chasing the Roadrunner (*Speedibus cantcatchmi*) yet again. While running down the road, they come to a deep gorge, 15.0 m straight across and 100 m deep. The Roadrunner launches himself across the gorge at a launch angle of 15º above the horizontal, and lands with 1.5 m to spare. (*a*) What was the Roadrunner's launch speed? (*b*) Wile E. Coyote launches himself across the gorge with the same initial speed, but at a different launch angle. To his horror, he is short the other lip by 0.50 m. What was his launch angle? (Assume that it was less than 15º.)

Picture the Problem In the absence of air resistance, the accelerations of both Wiley Coyote and the Roadrunner are constant and we can use constant-acceleration equations to express their coordinates at any time during their leaps across the gorge. By eliminating the parameter t between these equations, we can obtain an expression that relates their y coordinates to their x coordinates and that we can solve for their launch angles.



(*a*) Using constant-acceleration equations, express the x coordinate of the Roadrunner while it is in flight across the gorge:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $a_x = 0$ and $v_{0x} = v_0 \cos\theta_0$,

$$x = (v_0 \cos\theta_0)t \qquad (1)$$

Using constant-acceleration equations, express the y coordinate of the Roadrunner while it is in flight across the gorge:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $a_y = -g$ and $v_{0y} = v_0 \sin\theta_0$,

$$y = (v_0 \sin\theta_0)t - \tfrac{1}{2}gt^2 \qquad (2)$$

Eliminate the variable t between equations (1) and (2) to obtain:

$$y = (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2 \qquad (3)$$

When $y = 0$, $x = R$ and equation (3) becomes:

$$0 = (\tan\theta_0)R - \frac{g}{2v_0^2\cos^2\theta_0}R^2$$

Using the trigonometric identity $\sin 2\theta = 2\sin\theta\cos\theta$, solve for v_0:

$$v_0 = \sqrt{\frac{Rg}{\sin 2\theta_0}}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{\frac{(16.5\,\text{m})(9.81\,\text{m/s}^2)}{\sin 30°}} = \boxed{18\,\text{m/s}}$$

(*b*) Letting *R* represent Wiley's range, solve equation (1) for his launch angle:

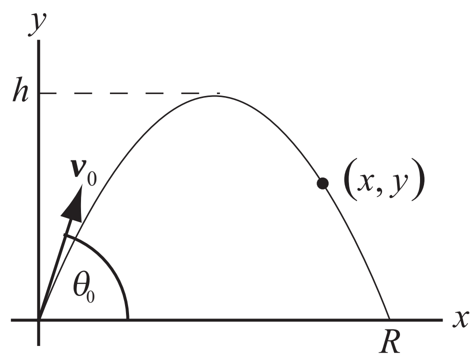
$$\theta_0 = \frac{1}{2}\sin^{-1}\left(\frac{Rg}{v_0^2}\right)$$

Substitute numerical values and evaluate θ_0:

$$\theta_0 = \frac{1}{2}\sin^{-1}\left[\frac{(14.5\,\text{m})(9.81\,\text{m/s}^2)}{(18.0\,\text{m/s})^2}\right] = \boxed{13°}$$

82 •• A cannon barrel is elevated 45º above the horizontal. It fires a ball with a speed of 300 m/s. (*a*) What height does the ball reach? (*b*) How long is the ball in the air? (*c*) What is the horizontal range of the cannon ball? (Ignore any effects due to air resistance.)

Picture the Problem Because, in the absence of air resistance, the vertical and horizontal accelerations of the cannonball are constant, we can use constant-acceleration equations to express the ball's position and velocity as functions of time and acceleration. The maximum height of the ball and its time-of-flight are related to the components of its launch velocity.



(*a*) Using a constant-acceleration equation, relate *h* to the initial and final speeds of the cannon ball:

$$v^2 = v_{0y}^2 + 2a_y\Delta y$$

or, because $v = 0$, $a_y = -g$, and $\Delta y = h$,

$$0 = v_{0y}^2 - 2gh \Rightarrow h = \frac{v_{0y}^2}{2g}$$

The vertical component of the firing speed is given by:

$$v_{0y} = v_0\sin\theta_0$$

Substituting for v_{0y} gives:

$$h = \frac{v_0^2\sin^2\theta_0}{2g}$$

Substitute numerical values and evaluate *h*:

$$h = \frac{(300\,\text{m/s})^2\sin^2 45°}{2(9.81\,\text{m/s}^2)} = \boxed{2.3\,\text{km}}$$

(*b*) The total flight time of the cannon ball is given by:

$$\Delta t = t_{\text{up}} + t_{\text{dn}} = 2t_{\text{up}} = 2\frac{v_{0y}}{g} = \frac{2v_0\sin\theta_0}{g}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2(300\ \text{m/s})\sin 45°}{9.81\ \text{m/s}^2} = 43.2\ \text{s}$$
$$= \boxed{43\ \text{s}}$$

(*c*) Express the *x* coordinate of the cannon ball as a function of time:

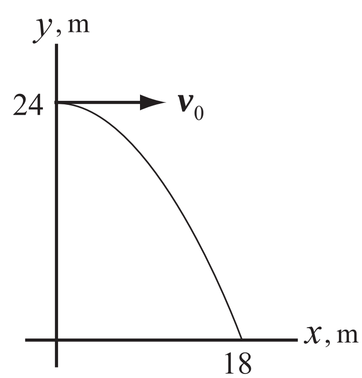
$$x = v_{0x}\Delta t = (v_0 \cos\theta_0)\Delta t$$

Evaluate *x* (= *R*) when Δt = 43.2 s:

$$x = [(300\ \text{m/s})\cos 45°](43.2\ \text{s})$$
$$= \boxed{9.2\ \text{km}}$$

83 •• [SSM] A stone thrown horizontally from the top of a 24-m tower hits the ground at a point 18 m from the base of the tower. (Ignore any effects due to air resistance.) (*a*) Find the speed with which the stone was thrown. (*b*) Find the speed of the stone just before it hits the ground.

Picture the Problem Choose a coordinate system in which the origin is at the base of the tower and the *x*- and *y*-axes are as shown in the figure to the right. In the absence of air resistance, the horizontal speed of the stone will remain constant during its fall and a constant-acceleration equation can be used to determine the time of fall. The final velocity of the stone will be the vector sum of its *x* and *y* components.



Because the stone is thrown horizontally:

$$v_x = v_{0x} = \frac{\Delta x}{\Delta t} \qquad (1)$$

(*a*) Using a constant-acceleration equation, express the vertical displacement of the stone as a function of the fall time:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because v_{0y} = 0 and $a = -g$,

$$\Delta y = -\tfrac{1}{2}g(\Delta t)^2 \Rightarrow \Delta t = \sqrt{-\frac{2\Delta y}{g}}$$

Substituting for Δt in equation (1) and simplifying yields:

$$v_x = \Delta x\sqrt{\frac{g}{-2\Delta y}}$$

Substitute numerical values and evaluate v_x:

$$v_x = (18\ \text{m})\sqrt{\frac{9.81\ \text{m/s}^2}{-2(-24\ \text{m})}} = \boxed{8.1\ \text{m/s}}$$

(*b*) The speed with which the stone hits the ground is related to the *x* and *y* components of its speed:

$$v=\sqrt{v_x^2+v_y^2} \qquad (2)$$

The *y* component of the stone's velocity at time *t* is:

$$v_y=v_{0y}-gt$$

or, because $v_{0y}=0$,

$$v_y=-gt$$

Substitute for v_x and v_y in equation (2) and simplify to obtain:

$$v=\sqrt{\left(\Delta x\sqrt{\frac{g}{-2\Delta y}}\right)^2+(-gt)^2}$$

$$=\sqrt{\frac{g(\Delta x)^2}{-2\Delta y}+g^2t^2}$$

Substitute numerical values and evaluate *v*:

$$v=\sqrt{\frac{(9.81\,\text{m/s}^2)(18\,\text{m})^2}{-2(-24\,\text{m})}+(9.81\,\text{m/s}^2)^2(2.21\,\text{s})^2}=\boxed{23\,\text{m/s}}$$

84 •• A projectile is fired into the air from the top of a 200-m cliff above a valley (Figure 3-36). Its initial velocity is 60 m/s at 60º above the horizontal. Where does the projectile land? (Ignore any effects due to air resistance.)

Picture the Problem In the absence of air resistance, the acceleration of the projectile is constant and its horizontal and vertical motions are independent of each other. We can use constant-acceleration equations to express the horizontal and vertical displacements of the projectile in terms of its time-of-flight.

Using a constant-acceleration equation, express the horizontal displacement of the projectile as a function of time:

$$\Delta x=v_{0x}\Delta t+\tfrac{1}{2}a_x(\Delta t)^2$$

or, because $v_{0x}=v_0\cos\theta_0$ and $a_x=0$,

$$\Delta x=(v_0\cos\theta_0)\Delta t$$

Using a constant-acceleration equation, express the vertical displacement of the projectile as a function of time:

$$\Delta y=v_{0y}\Delta t+\tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y}=v_0\sin\theta_0$ and $a_y=-g$,

$$\Delta y=(v_0\cos\theta_0)\Delta t-\tfrac{1}{2}g(\Delta t)^2$$

Substitute numerical values to obtain the quadratic equation:

$$-200\,\text{m}=(60\text{m/s})(\sin 60°)\Delta t-\tfrac{1}{2}(9.81\text{m/s}^2)(\Delta t)^2$$

Use the quadratic formula or your graphing calculator to obtain:

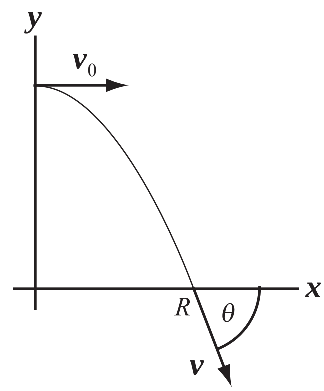
$\Delta t = 13.6\ \text{s}$

Substitute for Δt and evaluate the horizontal distance traveled by the projectile:

$$\Delta x = (60\ \text{m/s})(\cos 60°)(13.6\ \text{s}) = \boxed{0.41\,\text{km}}$$

85 •• The range of a cannonball fired horizontally from a cliff is equal to the height of the cliff. What is the direction of the velocity vector of the projectile as it strikes the ground? (Ignore any effects due to air resistance.)

Picture the Problem In the absence of air resistance, the acceleration of the cannonball is constant and its horizontal and vertical motions are independent of each other. Choose the origin of the coordinate system to be at the base of the cliff and the axes directed as shown and use constant-acceleration equations to describe both the horizontal and vertical displacements of the cannonball.



Express the direction of the velocity vector when the projectile strikes the ground:

$$\theta = \tan^{-1}\left(\frac{v_y}{v_x}\right) \qquad (1)$$

Express the vertical displacement using a constant-acceleration equation:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $a_y = -g$,

$$\Delta y = -\tfrac{1}{2}g(\Delta t)^2$$

Set $\Delta x = -\Delta y$ ($R = -h$) to obtain:

$$\Delta x = v_x\Delta t = \tfrac{1}{2}g(\Delta t)^2 \Rightarrow v_x = \frac{\Delta x}{\Delta t} = \tfrac{1}{2}g\Delta t$$

Find the y component of the projectile as it hits the ground:

$$v_y = v_{0y} + a\Delta t = -g\Delta t = -2v_x$$

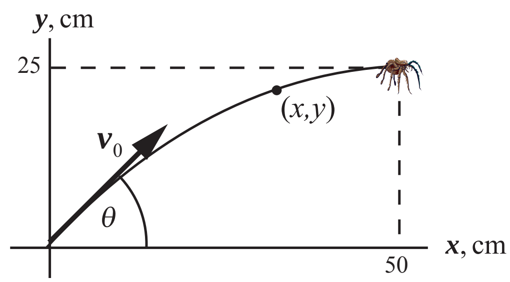
Substituting for v_y in equation (1) yields:

$$\theta = \tan^{-1}\left(\frac{-2v_x}{v_x}\right) = \tan^{-1}(-2) = \boxed{-63.4°}$$

86 •• An archerfish launches a droplet of water from the surface of a small lake at an angle of 60° above the horizontal. He is aiming at a juicy spider sitting on a leaf 50 cm to the east and on a branch 25 cm above the water surface. The

fish is trying to knock the spider into the water so that the fish may eat the spider. (*a*) What must the speed of the water droplet be for the fish to be successful? (*b*) When it hits the spider, is the droplet rising or falling?

Picture the Problem The diagram to the right shows the trajectory of the water droplet launched by the archerfish. We can use constant-acceleration equations to derive expressions for the required speed of the droplet and for the vertical velocity of the droplet as a function of its position.



(*a*) Use a constant-acceleration equation to express the *x*- and *y*-coordinates of the droplet:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$
and
$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

Because $x_0 = y_0 = 0$, $v_{0x} = v_0\cos\theta$, $v_{0y} = v_0\sin\theta$, and, in the absence of air resistance, $a_x = 0$:

$$x = (v_0 \cos\theta)t \qquad (1)$$
and
$$y = (v_0 \sin\theta)t - \tfrac{1}{2}gt^2 \qquad (2)$$

Solve equation (1) for *t* to obtain:

$$t = \frac{x}{v_0\cos\theta}$$

Substituting for *t* in equation (2) yields:

$$y = (v_0 \sin\theta)\left(\frac{x}{v_0\cos\theta}\right) - \tfrac{1}{2}g\left(\frac{x}{v_0\cos\theta}\right)^2$$

Simplify this equation to obtain:

$$y = (\tan\theta)x - \left(\frac{g}{2v_0^2\cos^2\theta}\right)x^2$$

Solving for v_0 yields:

$$v_0 = \sqrt{\frac{g}{2(x\tan\theta - y)\cos^2\theta}}\,x$$

When the droplet hits the spider, its coordinates must be $x = 0.50$ m and $y = 0.25$ m. Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{\frac{9.81\,\text{m/s}^2}{2((0.50\,\text{m})\tan 60° - 0.25\,\text{m})\cos^2 60°}}(0.50\,\text{m}) = 2.822\,\text{m/s} = \boxed{2.8\,\text{m/s}}$$

(*b*) Use a constant-acceleration equation to express the y component of the speed of the droplet as a function of time:

$$v_y(t) = v_{0y} + a_y t$$

or, because $v_{0y} = v_0 \sin\theta$ and $a_y = -g$,

$$v_y(t) = v_0 \sin\theta - gt \qquad (3)$$

From equation (1), the time-to-the-target, $t_{\text{to target}}$, is given by:

$$t_{\text{to target}} = \frac{x_{\text{target}}}{v_x} = \frac{x_{\text{target}}}{v_{0x}} = \frac{x_{\text{target}}}{v_0 \cos\theta}$$

where x_{target} is the x-coordinate of the target.

Substitute in equation (3) to obtain:

$$v_y(t_{\text{to target}}) = v_0 \sin\theta - g t_{\text{to target}} = v_0 \sin\theta - \frac{g x_{\text{target}}}{v_0 \cos\theta}$$

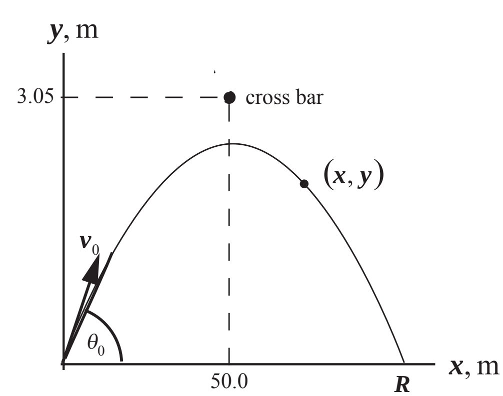
Substitute numerical values and evaluate $v_y(t_{\text{to target}})$:

$$v_y(t_{\text{to target}}) = (2.822\ \text{m/s})\sin 60° - \frac{(9.81\ \text{m/s}^2)(0.50\ \text{m})}{(2.822\ \text{m/s})\cos 60°} = -1.032\ \text{m/s}$$

Because the y-component of the velocity of the droplet is negative at the location of the spider, the droplet is falling and moving horizontally when it hits the spider.

87 •• [SSM] You are trying out for the position of place-kicker on a professional football team. With the ball teed up 50.0 m from the goalposts with a crossbar 3.05 m off the ground, you kick the ball at 25.0 m/s and 30° above the horizontal. (*a*) Is the field goal attempt good? (*b*) If so, by how much does it clear the bar? If not, by how much does it go under the bar? (*c*) How far behind the plane of the goalposts does the ball land?

Picture the Problem We can use constant-acceleration equations to express the x and y coordinates of the ball along its flight path. Eliminating t between the equations will leave us with an equation for y as a function of x that we can use to find the height of the ball when it has reached the cross bar. We can use this same equation to find the range of the ball and, hence, how far behind the plane of the goalposts the ball lands.



(*a*) Use a constant-acceleration equation to express the x coordinate of the ball as a function of time:

$$x(t) = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta_0$, and $a_x = 0$,

$$x(t) = (v_0\cos\theta_0)t \Rightarrow t = \frac{x(t)}{v_0\cos\theta_0}$$

Use a constant-acceleration equation to express the y coordinate of the ball as a function of time:

$$y(t) = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $v_{0y} = v_0\sin\theta_0$, and $a_y = -g$,

$$y(t) = (v_0\sin\theta_0)t - \tfrac{1}{2}gt^2$$

Substituting for t yields:

$$y(x) = (v_0\sin\theta_0)\frac{x(t)}{v_0\cos\theta_0} - \tfrac{1}{2}g\left(\frac{x(t)}{v_0\cos\theta_0}\right)^2$$

Simplify to obtain:

$$y(x) = (\tan\theta_0)x(t) - \frac{g}{2v_0^2\cos^2\theta_0}(x(t))^2$$

Substitute numerical values and evaluate $y(50.0\text{ m})$:

$$y(50.0\text{ m}) = (\tan 30°)(50.0\text{ m}) - \frac{9.81\text{ m/s}^2}{2(25.0\text{ m/s})^2\cos^2 30°}(50.0\text{ m})^2 = 2.71\text{ m}$$

Because 2.71 m < 3.05 m, the ball goes under the crossbar and the kick is no good.

(*b*) The ball goes under the bar by:

$$d_{\text{under}} = 3.05\text{ m} - 2.71\text{ m} = \boxed{0.34\text{ m}}$$

(*c*) The distance the ball lands behind the goalposts is given by:

$$d_{\substack{\text{behind the}\\ \text{goal posts}}} = R - 50.0\text{ m} \qquad (3)$$

Evaluate the equation derived in (*a*) for $y = 0$ and $x(t) = R$:

$$0 = (\tan\theta_0)R - \frac{g}{2v_0^2\cos^2\theta_0}R^2$$

Solving for v_0 yields:

$$R = \frac{v_0^2\sin 2\theta_0}{g}$$

Substitute for R in equation (3) to obtain:

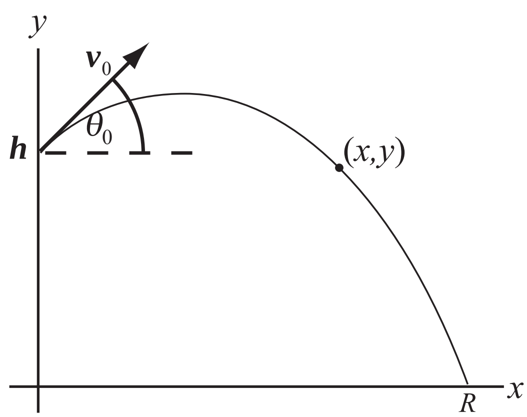
$$d_{\substack{\text{behind the}\\\text{goal posts}}} = \frac{v_0^2 \sin 2\theta_0}{g} - 50.0\text{ m}$$

Substitute numerical values and evaluate $d_{\substack{\text{behind the}\\\text{goal posts}}}$:

$$d_{\substack{\text{behind the}\\\text{goal posts}}} = \frac{(25.0\text{ m/s})^2 \sin 2(30°)}{9.81\text{ m/s}^2} - 50.0\text{ m} = \boxed{5.2\text{ m}}$$

88 •• The speed of an arrow fired from a compound bow is about 45.0 m/s. (*a*) A Tartar archer sits astride his horse and launches an arrow into the air, elevating the bow at an angle of 10º above the horizontal. If the arrow is 2.25 m above the ground at launch, what is the arrow's horizontal range? Assume that the ground is level, and ignore any effects due to air resistance. (*b*) Now assume that his horse is at full gallop and moving in the same direction as the direction the archer will fire the arrow. Also assume that the archer elevates the bow at the same elevation angle as in Part (*a*) and fires. If the horse's speed is 12.0 m/s, what is the arrow's horizontal range now?

Picture the Problem Choose a coordinate system in which the origin is at ground level. Let the positive x direction be to the right and the positive y direction be upward. We can apply constant-acceleration equations to obtain equations in time that relate the range to the initial horizontal speed and the height h to which the initial upward speed. Eliminating time from these equations will leave us with a quadratic equation in R, the solution to which will give us the range of the arrow. In (*b*), we'll find the launch speed and angle as viewed by an observer who is at rest on the ground and then use these results to find the arrow's range when the horse is moving at 12.0 m/s.



(*a*) Use constant-acceleration equations to express the horizontal and vertical coordinates of the arrow's motion:

$\Delta x = x - x_0 = v_{0x}t$

and

$y = h + v_{0y}t + \frac{1}{2}(-g)t^2$

where

$v_{0x} = v_0 \cos\theta_0$ and $v_{0y} = v_0 \sin\theta_0$

Solve the x-component equation for time:

$$t = \frac{\Delta x}{v_{0x}} = \frac{\Delta x}{v_0 \cos\theta_0}$$

Eliminating time from the y-component equation yields:

$$y = h + v_{0y}\frac{\Delta x}{v_{0x}} - \frac{1}{2}g\left(\frac{\Delta x}{v_{0x}}\right)^2$$

When $y = 0$, $\Delta x = R$ and:

$$0 = h + (\tan\theta_0)R - \frac{g}{2v_0^2\cos^2\theta_0}R^2$$

Solve for the range R to obtain:

$$R = \frac{v_0^2}{2g}\sin 2\theta_0\left(1 + \sqrt{1 + \frac{2gh}{v_0^2\sin^2\theta_0}}\right)$$

Substitute numerical values and evaluate R:

$$R = \frac{(45.0\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)}\sin 20°\left(1 + \sqrt{1 + \frac{2(9.81\,\text{m/s}^2)(2.25\,\text{m})}{(45.0\,\text{m/s})^2(\sin^2 10°)}}\right) = \boxed{82\,\text{m}}$$

(b) Express the speed of the arrow in the horizontal direction:

$$\begin{aligned} v_x &= v_{\text{arrow}} + v_{\text{archer}} \\ &= (45.0\,\text{m/s})\cos 10° + 12.0\,\text{m/s} \\ &= 56.32\,\text{m/s} \end{aligned}$$

Express the vertical speed of the arrow:

$$v_y = (45.0\,\text{m/s})\sin 10° = 7.814\,\text{m/s}$$

Express the angle of elevation from the perspective of someone on the ground:

$$\theta_0 = \tan^{-1}\left(\frac{v_y}{v_x}\right)$$

Substitute numerical values and evaluate θ_0 :

$$\theta_0 = \tan^{-1}\left(\frac{7.814\,\text{m/s}}{56.32\,\text{m/s}}\right) = 7.899°$$

The arrow's speed relative to the ground is given by:

$$v_0 = \sqrt{v_x^2 + v_y^2}$$

Substitute numerical values and evaluate v_0:

$$\begin{aligned} v_0 &= \sqrt{(56.32\,\text{m/s})^2 + (7.814\,\text{m/s})^2} \\ &= 56.86\,\text{m/s} \end{aligned}$$

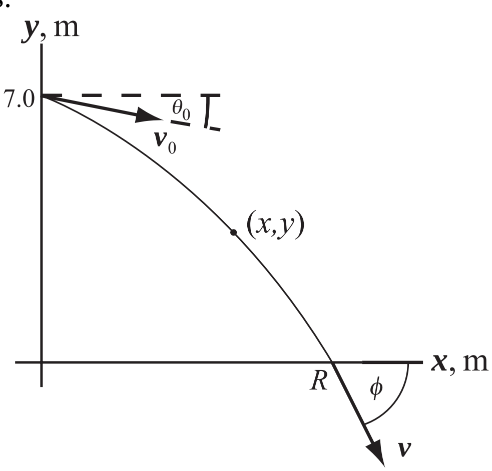
Substitute numerical values and evaluate R:

$$R=\frac{(56.86\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)}\sin(15.8°)\left(1+\sqrt{1+\frac{2(9.81\,\text{m/s}^2)(2.25\,\text{m})}{(56.86\,\text{m/s})^2(\sin^2 7.899°)}}\right)=\boxed{0.10\,\text{km}}$$

Remarks: An alternative solution for part (*b*) is to solve for the range in the reference frame of the archer and then add to it the distance the frame travels, relative to Earth, during the time of flight.

89 •• [SSM] The roof of a two-story house makes an angle of 30° with the horizontal. A ball rolling down the roof rolls off the edge at a speed of 5.0 m/s. The distance to the ground from that point is about two stories or 7.0 m. (*a*) How long is the ball in the air? (*b*) How far from the base of the house does it land? (*c*) What is its speed and direction just before landing?

Picture the Problem Choosing the coordinate system shown in the figure to the right, we can use a constant acceleration equation to express the *y* coordinate of the ball's position as a function of time. When the ball hits the ground, this position coordinate is zero and we can solve the resulting quadratic equation for the time-to-the-ground. Because, in the absence of air resistance, there is no acceleration in the horizontal direction we can find *R, v,* and ϕ using constant-acceleration equations.



(*a*) Use a constant-acceleration equation to relate the *y* coordinate of the ball to its time-in-flight:

$$y(t)=y_0+v_{0y}t+\tfrac{1}{2}a_y t^2$$

or, because $v_{0y}=v_0\sin\theta_0$ and $a_y=-g$,

$$y(t)=y_0+(v_0\sin\theta_0)t-\tfrac{1}{2}gt^2$$

$y(t_{\text{ground}})=0$ when the ball hits the ground and:

$$0=y_0+(v_0\sin\theta_0)t_{\text{ground}}-\tfrac{1}{2}gt_{\text{ground}}^2$$

Substitute numerical values to obtain:

$$0 = 7.0\text{ m} + (-5.0\text{ m/s})\sin 30^\circ\, t_{\text{ground}} - \tfrac{1}{2}(9.81\text{ m/s}^2)t_{\text{ground}}^2$$

Simplifying yields:

$$(4.91\text{ m/s}^2)t_{\text{ground}}^2 + (2.50\text{ m/s})t_{\text{ground}} - 7.0\text{ m} = 0$$

Use the quadratic formula or your graphing calculator to obtain:

$$t_{\text{ground}} = 0.966\text{ s or } -1.48\text{ s}$$

Because only the positive root has physical meaning:

$$t_{\text{ground}} = \boxed{0.97\text{ s}}$$

(*b*) The distance from the house *R* is related to the ball's horizontal speed and the time-to-ground:

$$R = v_{0x}t_{\text{ground}} = (v_0\cos\theta_0)t_{\text{ground}}$$

Substitute numerical values and evaluate *R*:

$$R = (5.0\text{ m/s})(\cos 30^\circ)(0.966\text{ s}) = \boxed{4.2\text{ m}}$$

(*c*) The speed and direction of the ball just before landing are given by:

$$v = \sqrt{v_x^2 + v_y^2} \qquad (1)$$

and

$$\phi = \tan^{-1}\left(\frac{v_y}{v_x}\right) \qquad (2)$$

Express v_x and v_y in terms of v_0:

$$v_x = v_0\cos\theta_0$$

and

$$v_y = v_{0y} + a_y t = v_0\sin\theta_0 + gt$$

Substitute numerical values and evaluate v_x and v_y:

$$v_x = (5.0\text{ m/s})\cos 30^\circ = 4.330\text{ m/s}$$

and

$$v_y = (5.0\text{ m/s})\sin 30^\circ + (9.81\text{ m/s}^2)(0.966\text{ s}) = 11.98\text{ m/s}$$

Substituting numerical values in equations (1) and (2) yields:

$$v=\sqrt{(4.330\text{ m/s})^2+(11.98\text{ m/s})^2}=\boxed{13\text{ m/s}}$$

and

$$\phi=\tan^{-1}\left(\frac{11.98\text{ m/s}}{4.330\text{ m/s}}\right)=\boxed{70^\circ\text{ below the horizontal}}$$

90 •• Compute $dR/d\theta_0$ from $R=(v_0^2/g)\sin(2\theta_0)$ and show that setting $dR/d\theta_0=0$ gives $\theta_0=45°$ for the maximum range.

Picture the Problem An extreme value (i.e., a maximum or a minimum) of a function is determined by setting the appropriate derivative equal to zero. Whether the extremum is a maximum or a minimum can be determined by evaluating the second derivative at the point determined by the first derivative.

Evaluate $dR/d\theta_0$:

$$\frac{dR}{d\theta_0}=\frac{v_0^2}{g}\frac{d}{d\theta_0}\left[\sin(2\theta_0)\right]=\frac{2v_0^2}{g}\cos(2\theta_0)$$

Set $dR/d\theta_0=0$ for extrema:

$$\frac{2v_0^2}{g}\cos(2\theta_0)=0$$

Solve for θ_0 to obtain:

$$\theta_0=\tfrac{1}{2}\cos^{-1}(0)=45^\circ$$

Determine whether 45° corresponds to a maximum or a minimum value of R:

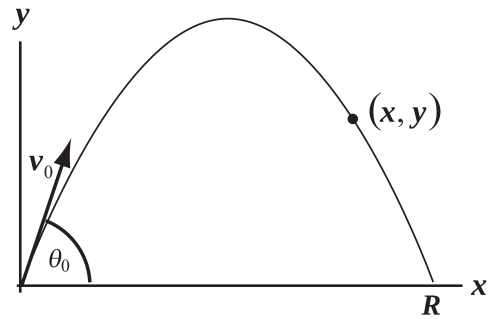
$$\left.\frac{d^2R}{d\theta_0^2}\right|_{\theta_0=45^\circ}=\left[-4\left(v_0^2/g\right)\sin 2\theta_0\right]_{\theta_0=45^\circ}<0$$

Therefore R is a maximum at $\theta_0=45°$.

91 •• In a science fiction short story written in the 1970s, Ben Bova described a conflict between two hypothetical colonies on the moon—one founded by the United States and the other by the USSR. In the story, colonists from each side started firing bullets at each other, only to find to their horror that their rifles had large enough muzzle velocities that the bullets went into orbit. (*a*) If the magnitude of free-fall acceleration on the moon is 1.67 m/s^2, what is the maximum range of a rifle bullet with a muzzle velocity of 900 m/s? (Assume the curvature of the surface of the moon is negligible.) (*b*) What would the muzzle velocity have to be to send the bullet into a circular orbit just above the surface of the moon?

Picture the Problem We can use constant-acceleration equations to express the x and y coordinates of a bullet in flight on the moon as a function of t. Eliminating this parameter will yield an expression for y as a function of x that we can use to

find the range of the bullet. The necessity that the centripetal acceleration of an object in orbit at the surface of a body equals the acceleration due to gravity at the surface will allow us to determine the required muzzle velocity for orbital motion.



(*a*) Using a constant-acceleration equation, express the *x* coordinate of a bullet in flight on the moon:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $a_x = 0$ and $v_{0x} = v_0\cos\theta_0$,

$$x = (v_0 \cos\theta_0)t$$

Using a constant-acceleration equation, express the *y* coordinate of a bullet in flight on the moon:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $a_y = -g_{\text{moon}}$ and $v_{0y} = v_0\sin\theta_0$,

$$y = (v_0 \sin\theta_0)t - \tfrac{1}{2}g_{\text{moon}}t^2$$

Using the *x*-component equation, eliminate time from the *y*-component equation to obtain:

$$y = (\tan\theta_0)x - \frac{g_{\text{moon}}}{2v_0^2\cos^2\theta_0}x^2$$

When $y = 0$ and $x = R$:

$$0 = (\tan\theta_0)R - \frac{g_{\text{moon}}}{2v_0^2\cos^2\theta_0}R^2$$

and

$$R = \frac{v_0^2}{g_{\text{moon}}}\sin 2\theta_0$$

Substitute numerical values and evaluate *R*:

$$R = \frac{(900\,\text{m/s})^2}{1.67\,\text{m/s}^2}\sin 90° = \boxed{485\,\text{km}}$$

This result is probably not very accurate because it is about 28% of the moon's radius (1740 km). This being the case, we can no longer assume that the ground is "flat" because of the curvature of the moon.

(*b*) Express the condition that the centripetal acceleration must satisfy for an object in orbit at the surface of the moon:

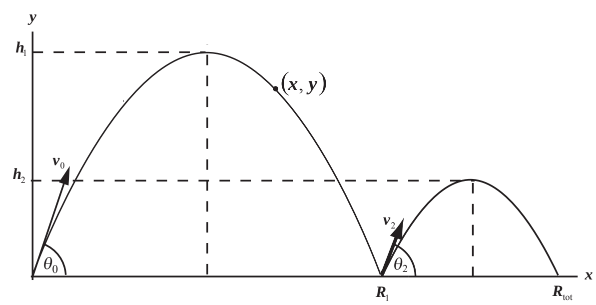
$$a_c = g_{\text{moon}} = \frac{v^2}{r} \Rightarrow v = \sqrt{g_{\text{moon}}r}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(1.67\,\text{m/s}^2)(1.74\times10^6\,\text{m})} = \boxed{1.70\,\text{km/s}}$$

92 ••• On a level surface, a ball is launched from ground level at an angle of 55° above the horizontal, with an initial speed of 22 m/s. It lands on a hard surface, and bounces, reaching a peak height of 75% of the height it reached on its first arc. (Ignore any effects due to air resistance.) (*a*) What is the maximum height reached in its first parabolic arc? (*b*) How far horizontally from the launch point did it strike the ground the first time? (*c*) How far horizontally from the launch point did the ball strike the ground the second time? Assume the horizontal component of the velocity remains constant during the collision of the ball with the ground. *Note: You cannot assume the angle with which the ball leaves the ground after the first collision is the same as the initial launch angle.*

Picture the Problem The following diagram shows a convenient coordinate system to use in solving this problem as well as the relevant distances and angles. We can use constant-acceleration equations to find h_1. In (*b*) we can use the same-elevation equation to find R_1. In (*c*) we know the speed with which the tennis ball hits the ground on its first bounce – this is simply the speed with which it was launched. As it collides with the ground, it accelerates such that it leaves the surface with a speed that is reduced and is directed generally upward again. We are told that it reaches a height of 75% of its first peak height, and to assume that there is no horizontal acceleration. Again, we can use constant-acceleration equations to find θ_2 and the components of $\vec{v}_2$ and hence the range of the ball after its bounce. We can then find the total range from the sum of the ranges before and after the bounce.



(*a*) Use constant-acceleration equations to express the x and y coordinates of the tennis ball along its first parabolic trajectory as functions of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2 \qquad (1)$$

and

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2 \qquad (2)$$

Because $x_0 = 0$, $v_{0x} = v_0\cos\theta_0$, and $a_x = 0$, equation (1) becomes:

$$x = (v_0\cos\theta_0)t \qquad (3)$$

Because $y_0 = 0$, $v_{0y} = v_0 \sin\theta_0$, and $a_y = -g$, equation (2) becomes:

$$y = (v_0 \sin\theta_0)t - \tfrac{1}{2}gt^2 \qquad (4)$$

Use a constant-acceleration equation to relate the vertical velocity of the ball to time:

$$v_y = v_{0y} + a_y t = v_0 \sin\theta_0 - gt$$

When the ball is at the top of its trajectory $v_y = 0$ and:

$$0 = v_0 \sin\theta_0 - gt_{\text{top of trajectory}}$$

Solving for $t_{\text{top of trajectory}}$ yields:

$$t_{\text{top of trajectory}} = \frac{v_0 \sin\theta_0}{g}$$

Substitute in equation (4) and simplify to obtain:

$$h_1 = (v_0 \sin\theta_0)\left(\frac{v_0 \sin\theta_0}{g}\right) - \tfrac{1}{2}g\left(\frac{v_0 \sin\theta_0}{g}\right)^2 = \frac{v_0^2 \sin^2\theta_0}{2g}$$

Substitute numerical values and evaluate h_1:

$$h_1 = \frac{(22\ \text{m/s})^2 \sin^2 55^\circ}{2(9.81\ \text{m/s}^2)} = 16.55\ \text{m}$$
$$= \boxed{17\ \text{m}}$$

(*b*) The same-elevation range equation is:

$$R = \frac{v_0^2}{g}\sin 2\theta_0$$

Substitute numerical values and evaluate R_1:

$$R_1 = \frac{(22\ \text{m/s})^2}{9.81\ \text{m/s}^2}\sin 2(55^\circ) = 46.36\ \text{m}$$
$$= \boxed{46\ \text{m}}$$

(*c*) The total range of the ball is the sum of the ranges R_1 and R_2:

$$R_{\text{tot}} = R_1 + R_2 \qquad (5)$$

Provided we can determine the initial velocity v_{20} and rebound angle θ_2 of the rebounding ball, we can use the same-elevation equation to find R_2:

$$R_2 = \frac{v_{20}^2}{g}\sin 2\theta_2 \qquad (6)$$

where

$$v_{20}^2 = v_{2x}^2 + v_{2y}^2 \qquad (7)$$

Substituting equation (6) in equation (7) yields:

$$R_2 = \frac{v_{2x}^2 + v_{2y}^2}{g}\sin 2\theta_2 \qquad (8)$$

Use a constant-acceleration equation to relate the rebound height h_2 to the y component of the rebound velocity:

$$v_2^2 = v_{2y}^2 + 2a_y h_2$$

or, because $v_2 = 0$ and $a_y = -g$,

$$0 = v_{2y}^2 - 2gh_2$$

Solving for v_{2y} yields:

$$v_{2y}^2 = 2gh_2$$

or, because $h_2 = 0.75h_1$,

$$v_{2y}^2 = 1.5gh_1 \qquad (9)$$

Because there is no horizontal acceleration, the ball continues with the same horizontal velocity it originally had:

$$v_{2x} = v_{1x} = v_0 \cos\theta_0$$

and

$$v_{2x}^2 = v_0^2 \cos^2\theta_0 \qquad (10)$$

The rebound angle θ_2 is given by:

$$\theta_2 = \tan^{-1}\left(\frac{v_{2y}}{v_{2x}}\right)$$

Substituting for v_{2y} and v_{2x} and simplifying yields:

$$\theta_2 = \tan^{-1}\left(\frac{\sqrt{1.5gh_1}}{v_0 \cos\theta_0}\right)$$

Substitute numerical values and evaluate θ_2:

$$\boldsymbol{\theta}_2 = \tan^{-1}\left(\frac{\sqrt{1.5(9.81\text{ m/s}^2)(16.55\text{ m})}}{(22\text{ m/s})\cos 55°}\right) = 51.04°$$

Substitute (9) and (10) in equation (8) to obtain:

$$R_2 = \frac{v_0^2 \cos^2\theta_0 + 1.5gh_1}{g}\sin 2\theta_2$$

Substitute numerical values and evaluate R_2:

$$R_2 = \frac{(22\text{ m/s})^2 \cos^2 55° + 1.5\left(9.81\text{ m/s}^2\right)(16.55\text{ m})}{9.81\text{ m/s}^2}\sin 2\left(51.04°\right) = 40.15\text{ m}$$

Substitute numerical values for R_1 and R_2 in equation (5) and evaluate R_{tot}:

$$R_{\text{tot}} = 46.36\text{ m} + 40.15\text{ m} = \boxed{87\text{ m}}$$

93 ••• In the text, we calculated the range for a projectile that lands at the same elevation from which it is fired as $R = (v_0^2 / g)\sin 2\theta_0$. A golf ball hit from an elevated tee at 45.0 m/s and an angle of 35.0° lands on a green 20.0 m below the tee (Figure 3-37). (Ignore any effects due to air resistance.) (*a*) Calculate the range using the same elevation equation $R = (v_0^2 / g)\sin 2\theta_0$ even though the ball is hit from an elevated tee. (*b*) Show that the range for the more general problem

(Figure 3-37) is given by $R=\left(1+\sqrt{1-\dfrac{2gy}{v_0^2\sin^2\theta_0}}\right)\dfrac{v_0^2}{2g}\sin 2\theta_0$, where y is the height of the tee above the green. That is, $y=-h$. (*c*) Compute the range using this formula. What is the percentage error in neglecting the elevation of the green?

Picture the Problem The initial position is on the $+y$ axis and the point of impact is on the $+x$ axis, with the x axis horizontal and the y axis vertical. We can apply constant-acceleration equations to express the horizontal and vertical coordinates of the projectile as functions of time. Solving these equations simultaneously will leave us with a quadratic equation in R, the solution to which is the result we are required to establish.

(*a*) The same elevation equation is:

$$R_{\substack{\text{same}\\\text{elevation}}}=\frac{v_0^2}{g}\sin 2\theta_0$$

Substitute numerical values and evaluate $R_{\substack{\text{same}\\\text{elevation}}}$:

$$R_{\substack{\text{same}\\\text{elevation}}}=\frac{(45.0\text{ m/s})^2}{9.81\text{ m/s}^2}\sin 2(35.0°)=\boxed{194\text{ m}}$$

(*b*) Write the constant-acceleration equations for the horizontal and vertical components of the projectile's motion:

$$x=v_{0x}t$$

and

$$y=h+v_{0y}t+\tfrac{1}{2}(-g)t^2$$

where

$v_{0x}=v_0\cos\theta_0$ and $v_{0y}=v_0\sin\theta_0$

Solve the x-component equation for t to obtain:

$$t=\frac{x}{v_{0x}}=\frac{x}{v_0\cos\theta_0}$$

Using the x-component equation, eliminate time from the y-component equation to obtain:

$$y=h+(\tan\theta_0)x-\frac{g}{2v_0^2\cos^2\theta_0}x^2$$

When the projectile strikes the ground its coordinates are (R, 0) and our equation becomes:

$$0=h+(\tan\theta_0)R-\frac{g}{2v_0^2\cos^2\theta_0}R^2$$

Using the plus sign in the quadratic formula to ensure a physically meaningful root (one that is positive), solve for the range to obtain:

$$R=\left(1+\sqrt{1+\frac{2gh}{v_0^2\sin^2\theta_0}}\right)\frac{v_0^2}{2g}\sin 2\theta_0$$

Because $y = -h$:

$$\boxed{R = \left(1 + \sqrt{1 - \frac{2gy}{v_0^2 \sin^2 \theta_0}}\right)\frac{v_0^2}{2g}\sin 2\theta_0}$$

(c) Substitute numerical values and evaluate R:

$$R = \left(1 + \sqrt{1 - \frac{2(9.81\,\text{m/s}^2)(-20.0\,\text{m})}{(45.0\,\text{m/s})^2 \sin^2 35.0°}}\right)\frac{(45.0\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)}\sin 2(35.0°) = \boxed{219\,\text{m}}$$

The percent error is given by:

$$\%\,\text{error} = \left|\frac{R - R_{\substack{\text{same}\\\text{elevation}}}}{R}\right|$$

Substitute numerical values and evaluate the percent error:

$$\%\,\text{error} = \left|\frac{219\,\text{m} - 194\,\text{m}}{219\,\text{m}}\right| = \boxed{11\%}$$

Remarks: Note that, for $y = -h$, the equation derived in Part (b) reduces to $R = (v_0^2/g)\sin 2\theta_0$, in agreement with the first equation in the problem statement.

94 ••• In the text, we calculated the range for a projectile that lands at the same elevation from which it is fired as $R = (v_0^2/g)\sin 2\theta_0$ if the effects of air resistance are negligible. (a) Show that for the same conditions the change in the range for a small change in free-fall acceleration g, and the same initial speed and angle, is given by $\Delta R/R = -\Delta g/g$. (b) What would be the length of a homerun at a high altitude where g is 0.50% less than at sea level if the homerun at sea level traveled 400 ft?

Picture the Problem We can show that $\Delta R/R = -\Delta g/g$ by differentiating R with respect to g and then using a differential approximation.

(a) Differentiate the range equation with respect to g:

$$\frac{dR}{dg} = \frac{d}{dg}\left(\frac{v_0^2}{g}\sin 2\theta_0\right) = -\frac{v_0^2}{g^2}\sin 2\theta_0$$
$$= -\frac{R}{g}$$

Approximate dR/dg by $\Delta R/\Delta g$:

$$\frac{\Delta R}{\Delta g} = -\frac{R}{g}$$

Separate the variables to obtain:

$$\frac{\Delta R}{R} = \boxed{-\frac{\Delta g}{g}}$$

That is, for small changes in gravity ($g \approx g \pm \Delta g$), the fractional change in R is linearly opposite to the fractional change in g.

(*b*) Solve the proportion derived in (*a*) for ΔR to obtain:

$$\Delta R = -\frac{\Delta g}{g} R$$

Substitute numerical values and evaluate ΔR:

$$\Delta R = -\frac{-0.0050g}{g}(400\text{ ft}) = 2\text{ ft}$$

The length of the homerun at this high-altitude location would be 402 ft.

Remarks: The result in (*a*) tells us that as gravity increases, the range will decrease, and vice versa. This is as it must be because *R* is inversely proportional to *g*.

95 ••• [SSM] In the text, we calculated the range for a projectile that lands at the same elevation from which it is fired as $R = \left(v_0^2/g\right)\sin 2\theta_0$ if the effects of air resistance are negligible. (*a*) Show that for the same conditions the change in the range for a small change in launch speed, and the same initial angle and free-fall acceleration, is given by $\Delta R/R = 2\Delta v_0/v_0$. (*b*) Suppose a projectile's range was 200 m. Use the formula in Part (*a*) to estimate its increase in range if the launch speed were increased by 20.0%. (*c*) Compare your answer in (*b*) to the increase in range by calculating the increase in range directly from $R = \left(v_0^2/g\right)\sin 2\theta_0$. If the results for Parts (*b*) and (*c*) are different, is the estimate too small or large, and why?

Picture the Problem We can show that $\Delta R/R = 2\Delta v_0/v_0$ by differentiating R with respect to v_0 and then using a differential approximation.

(*a*) Differentiate the range equation with respect to v_0:

$$\frac{dR}{dv_0} = \frac{d}{dv_0}\left(\frac{v_0^2}{g}\sin 2\theta_0\right) = \frac{2v_0}{g}\sin 2\theta_0$$
$$= 2\frac{R}{v_0}$$

Approximate dR/dv_0 by $\Delta R/\Delta v_0$:

$$\frac{\Delta R}{\Delta v_0} = 2\frac{R}{v_0}$$

Separate the variables to obtain:

$$\frac{\Delta R}{R}=\boxed{2\frac{\Delta v_0}{v_0}}$$

That is, for small changes in the launch velocity ($v_0 \approx v_0 \pm \Delta v_0$), the fractional change in R is twice the fractional change in v_0.

(*b*) Solve the proportion derived in (*a*) for ΔR to obtain:

$$\Delta R = 2R\frac{\Delta v_0}{v_0}$$

Substitute numerical values and evaluate ΔR:

$$\Delta R = 2(200\text{ m})\frac{0.20v_0}{v_0}=\boxed{80\text{ m}}$$

(*c*) The increase in range is given by:

$$\Delta R = R'-R \qquad (1)$$

The same-elevation equation is:

$$R=\frac{v_0^2}{g}\sin 2\theta_0$$

The longer range R' resulting from a 20.0% increase in the launch speed is given by:

$$R' = \frac{(v_0+0.20v_0)^2}{g}\sin 2\theta_0 = \frac{(1.20v_0)^2}{g}\sin 2\theta_0$$

Substituting for R and R' gives:

$$\Delta R = \frac{(1.20v_0)^2}{g}\sin 2\theta_0 - \frac{v_0^2}{g}\sin 2\theta_0 = \left[(1.20)^2-1\right]\frac{v_0^2}{g}\sin 2\theta_0 = 0.44R$$

Substitute the numerical value of R and evaluate ΔR:

$$\Delta R = 0.44(200\text{ m})=\boxed{88\text{ m}}$$

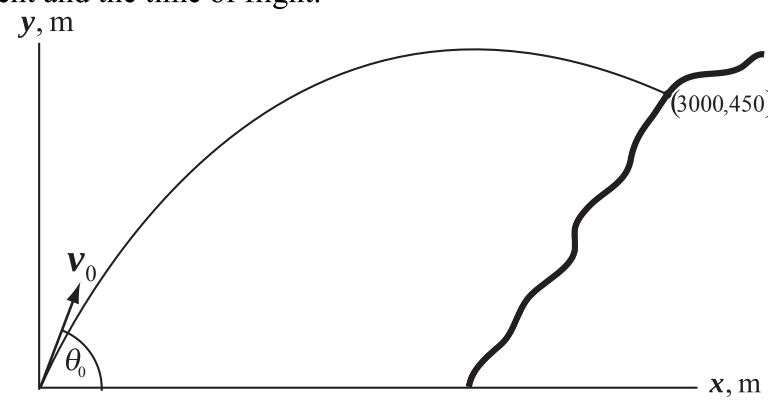
The approximate solution is smaller. The estimate ignores higher-order terms and they are important when the differences are not small.

Remarks: The result in (*a*) tells us that as launch velocity increases, the range will increase twice as fast, and vice versa.

96 ••• A projectile, fired with unknown initial velocity, lands 20.0 s later on the side of a hill, 3000 m away horizontally and 450 m vertically above its starting point. Neglect any effects due to air resistance. (*a*) What is the vertical component of its initial velocity? (*b*) What is the horizontal component of its initial velocity? (*c*) What was its maximum height above its launch point? (*d*) As it hit the hill,

what speed did it have and what angle did its velocity make with the vertical? (Ignore air resistance.)

Picture the Problem In the absence of air resistance, the horizontal and vertical displacements of the projectile are independent of each other and describable by constant-acceleration equations. Choose the origin at the firing location and with the coordinate axes as shown in the pictorial representation and use constant-acceleration equations to relate the vertical displacement to the vertical component of the initial velocity and the horizontal velocity to the horizontal displacement and the time of flight.



(*a*) Using a constant-acceleration equation, express the vertical displacement of the projectile as a function of its time of flight:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $a_y = -g$,

$$\Delta y = v_{0y}\Delta t - \tfrac{1}{2}g(\Delta t)^2 \quad (1)$$

Solve for v_{0y}:

$$v_{0y} = \frac{\Delta y + \frac{1}{2}g(\Delta t)^2}{\Delta t}$$

Substitute numerical values and evaluate v_{0y}:

$$v_{0y} = \frac{450\text{ m} + \frac{1}{2}(9.81\text{ m/s}^2)(20.0\text{ s})^2}{20.0\text{ s}}$$

$$= 120.6\text{ m/s} = \boxed{121\text{m/s}}$$

(*b*) The horizontal velocity remains constant, so:

$$v_{0x} = v_x = \frac{\Delta x}{\Delta t} = \frac{3000\text{ m}}{20.0\text{ s}} = \boxed{150\text{ m/s}}$$

(*c*) From equation (1) we have, when the projectile is at its maximum height *h*:

$$h = v_{0y}\Delta t - \tfrac{1}{2}g(\Delta t)^2$$

or, because $v_{0y} = v_0\sin\theta$,

$$h = (v_0\sin\theta_0)\Delta t - \tfrac{1}{2}g(\Delta t)^2 \quad (2)$$

Use a constant-acceleration equation to relate the y component of the velocity of the projectile to its initial value and to the elapsed time:

$$v_y = v_{0y} + a_y\Delta t = v_0 \sin\theta_0 - g\Delta t \quad (3)$$

The projectile is at its maximum height when its upward velocity is zero. Under this condition we have:

$$0 = v_0 \sin\theta_0 - g\Delta t \Rightarrow \Delta t = \frac{v_0 \sin\theta_0}{g}$$

Substitute for Δt in equation (2) to obtain:

$$h = (v_0 \sin\theta_0)\left(\frac{v_0 \sin\theta_0}{g}\right) - \tfrac{1}{2}g\left(\frac{v_0 \sin\theta_0}{g}\right)^2$$

Simplifying yields:

$$h = \frac{v_0^2 \sin^2\theta_0}{2g} \qquad (4)$$

v_0^2 is given by:

$$v_0^2 = v_{0x}^2 + v_{0y}^2$$

Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{(150\ \text{m/s})^2 + (120.6\ \text{m/s})^2} = 192.5\ \text{m/s}$$

The horizontal displacement of the projectile is given by:

$$\Delta x = v_{0x}\Delta t = (v_0 \cos\theta_0)\Delta t$$

Solving for the launch angle θ_0 gives:

$$\theta_0 = \cos^{-1}\left(\frac{\Delta x}{v_0 \Delta t}\right)$$

Substitute numerical values and evaluate θ_0:

$$\boldsymbol{\theta}_0 = \cos^{-1}\left(\frac{3000\ \text{m}}{(192.5\ \text{m/s})(20.0\ \text{s})}\right) = 38.80°$$

Substitute numerical values in equation (3) and evaluate h:

$$h = \frac{(192.5\ \text{m/s})^2 \sin^2 38.80°}{2(9.81\ \text{m/s}^2)} = \boxed{742\ \text{m}}$$

(*d*) Use equation (3) to evaluate $v_y(20.0\ \text{s})$:

$$v_y(20.0\ \text{s}) = 120.6\ \text{m/s} - (9.81\ \text{m/s}^2)(20.0\ \text{s}) = -75.60\ \text{m/s}$$

The speed of the projectile at impact is given by:

$$v(20.0\ \text{s}) = \sqrt{(v_x(20.0\ \text{s}))^2 + (v_y(20.0\ \text{s}))^2}$$

Substitute numerical values and evaluate $v(20.0\text{ s})$:

$$v(20.0\,\text{s}) = \sqrt{(150\,\text{m/s})^2 + (-75.6\,\text{m/s})^2} = \boxed{168\,\text{m/s}}$$

The angle at impact is given by:

$$\theta_{\text{impact}} = \tan^{-1}\left(\frac{v_y(20.0\,\text{s})}{v_x(20.0\,\text{s})}\right)$$

Substitute numerical values and evaluate θ_{impact}:

$$\theta_{\text{impact}} = \tan^{-1}\left(\frac{-75.60\,\text{m/s}}{150\,\text{m/s}}\right) = -26.75°$$
$$= \boxed{63.3° \text{ with the vertical}}$$

97 ••• A projectile is launched over level ground at an initial elevation angle of θ. An observer standing at the launch site sees the projectile at the point of its highest elevation, and measures the angle ϕ shown in Figure 3-38. Show that $\tan\phi = \frac{1}{2}\tan\theta$. (Ignore any effects due to air resistance.)

Picture the Problem We can use trigonometry to relate the maximum height of the projectile to its range and the sighting angle at maximum elevation and the range equation to express the range as a function of the launch speed and angle. We can use a constant-acceleration equation to express the maximum height reached by the projectile in terms of its launch angle and speed. Combining these relationships will allow us to conclude that $\tan\phi = \frac{1}{2}\tan\theta$.

Referring to the figure, relate the maximum height of the projectile to its range and the sighting angle ϕ:

$$\tan\phi = \frac{h}{\frac{1}{2}R}$$

Express the range of the rocket and use the trigonometric identity $\sin 2\theta = 2\sin\theta\cos\theta$ to rewrite the expression as:

$$R = \frac{v_0^2}{g}\sin(2\theta) = 2\frac{v_0^2}{g}\sin\theta\cos\theta$$

Using a constant-acceleration equation, relate the maximum height h of a projectile to the vertical component of its launch speed:

$$v_y^2 = v_{0y}^2 - 2gh$$

or, because $v_y = 0$ and $v_{0y} = v_0\sin\theta$,

$$v_0^2\sin^2\theta = 2gh \Rightarrow h = \frac{v_0^2}{2g}\sin^2\theta$$

Substitute for R and h and simplify to obtain:

$$\tan\phi = \frac{2\left(\dfrac{v_0^2}{2g}\sin^2\theta\right)}{2\left(\dfrac{v_0^2}{g}\sin\theta\cos\theta\right)} = \boxed{\tfrac{1}{2}\tan\theta}$$

98 ••• A toy cannon is placed on a ramp that has a slope of angle ϕ. (*a*) If the cannonball is projected up the hill at an angle of θ_0 above the horizontal (Figure 3-39) and has a muzzle speed of v_0, show that the range R of the cannonball (as measured along the ramp) is given by $R = \dfrac{2v_0^2\cos^2\theta_0(\tan\theta_0 - \tan\phi)}{g\cos\phi}$. Neglect any effects due to air resistance.

Picture the Problem The equation of a particle's trajectory is derived in the text so we'll use it as our starting point in this derivation. We can relate the coordinates of the point of impact (x, y) to the angle ϕ and use this relationship to eliminate y from the equation for the cannonball's trajectory. We can then solve the resulting equation for x and relate the horizontal component of the point of impact to the cannonball's range.

The equation of the cannonball's trajectory is given in Equation 3-22:

$$y(x) = (\tan\theta_0)x - \left(\frac{g}{2v_0^2\cos^2\theta_0}\right)x^2$$

Relate the x and y components of a point on the ground to the angle ϕ:

$$y(x) = (\tan\phi)x$$

Express the condition that the cannonball hits the ground:

$$(\tan\phi)x = (\tan\theta_0)x - \left(\frac{g}{2v_0^2\cos^2\theta_0}\right)x^2$$

Solving for x yields:

$$x = \frac{2v_0^2\cos^2\theta_0(\tan\theta_0 - \tan\phi)}{g}$$

Relate the range of the cannonball's flight R to the horizontal distance x:

$$x = R\cos\phi$$

Substitute to obtain:

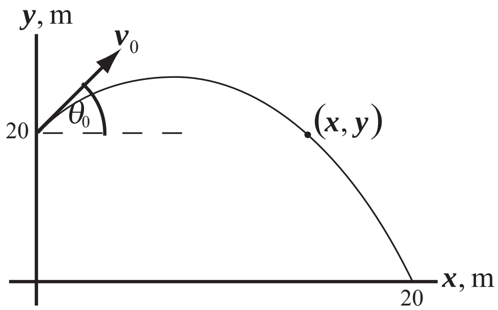
$$R\cos\phi = \frac{2v_0^2\cos^2\theta_0(\tan\theta_0 - \tan\phi)}{g}$$

Solving for R yields:

$$R = \boxed{\frac{2v_0^2\cos^2\theta_0(\tan\theta_0 - \tan\phi)}{g\cos\phi}}$$

99 ••• A rock is thrown from the top of a 20-m-high building at an angle of 53° above the horizontal. (*a*) If the horizontal range of the throw is equal to the height of the building, with what speed was the rock thrown? (*b*) How long is it in the air? (*c*) What is the velocity of the rock just before it strikes the ground? (Ignore any effects due to air resistance.)

Picture the Problem In the absence of air resistance, the acceleration of the rock is constant and the horizontal and vertical motions are independent of each other. Choose the coordinate system shown in the figure with the origin at the base of the building and the axes oriented as shown and apply constant-acceleration equations to relate the horizontal and vertical coordinates of the rock to the time into its flight.



(*a*) Using constant-acceleration equations, express the x and y coordinates of the rock as functions of the time into its flight:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$
and
$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

Because $x_0 = 0$, $a_x = 0$, and $a_y = -g$:

$$x = v_{0x}t = (v_0 \cos\theta_0)t \qquad (1)$$
and
$$y = y_0 + v_{0y}t - \tfrac{1}{2}gt^2$$
$$= y_0 + (v_0 \sin\theta_0)t - \tfrac{1}{2}gt^2$$

Eliminating time between these equations yields:

$$y = y_0 + (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2$$

When the rock hits the ground, $x = y_0$ and:

$$0 = y_0 + (\tan\theta_0)y_0 - \frac{g}{2v_0^2\cos^2\theta_0}y_0^2$$
or
$$0 = 1 + \tan\theta_0 - \frac{g}{2v_0^2\cos^2\theta_0}y_0$$

Solve for v_0 to obtain:

$$v_0 = \frac{1}{\cos\theta_0}\sqrt{\frac{gy_0}{2(1+\tan\theta_0)}}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \frac{1}{\cos 53^\circ}\sqrt{\frac{(9.81\ \text{m/s}^2)(20\ \text{m})}{2(1+\tan 53^\circ)}} = 10.79\ \text{m/s} \approx \boxed{11\ \text{m/s}}$$

(*b*) Solve equation (1) for the time-to-impact to obtain:

$$t = \frac{x}{v_0 \cos\theta_0}$$

Substitute numerical values and evaluate *t*:

$$t = \frac{20\,\text{m}}{(10.79\,\text{m/s})\cos 53°} = 3.08\,\text{s} = \boxed{3.1\,\text{s}}$$

(*c*) Using constant-acceleration equations, find v_y and v_x at impact:

$$v_x = v_{0x} = v_0 \cos\theta = (10.79\ \text{m/s})\cos 53° = 6.50\,\text{m/s}$$

and

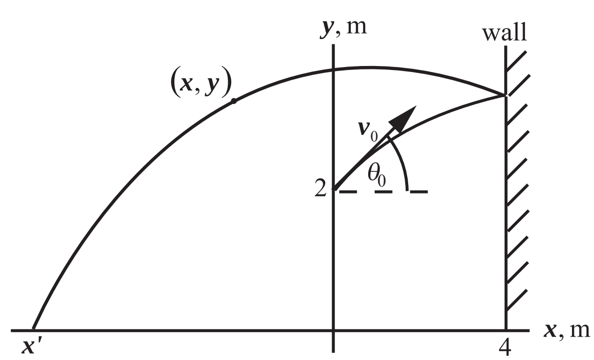
$$v_y = v_{0y} - gt = v_0 \sin\theta_0 - gt = (10.79\ \text{m/s})\sin 53° - (9.81\,\text{m/s}^2)\times(3.08\,\text{s}) = -21.6\,\text{m/s}$$

Expressing the velocity at impact in vector form gives:

$$\vec{\boldsymbol{v}} = \boxed{(6.5\,\text{m/s})\hat{\boldsymbol{i}} + (-22\ \text{m/s})\hat{\boldsymbol{j}}}$$

100 ••• A woman throws a ball at a vertical wall 4.0 m away (Figure 3-40). The ball is 2.0 m above ground when it leaves the woman's hand with an initial velocity of 14 m/s at 45º as shown. When the ball hits the wall, the horizontal component of its velocity is reversed; the vertical component remains unchanged. (*a*) Where does the ball hit the ground? (*b*) How long was the ball in the air before it hit the wall? (*c*) Where did the ball hit the wall? (*d*) How long was the ball in the air after it left the wall? Ignore any effects due to air resistance.

Picture the Problem Choose the coordinate system shown below with the positive *x* axis to the right and the positive *y* axis upward. The solid curve represents the trajectory of the ball as it bounces from the vertical wall. Because the ball experiences constant acceleration (except during its collision with the wall), we can use constant-acceleration equations to describe its motion.



(*a*) The ball hits the ground at a point x' whose coordinate is given by:

$$x' = \Delta x - 4.0\,\text{m} \qquad (1)$$

where Δx is the displacement of the ball after it hits the wall.

Using a constant-acceleration equation, express the vertical displacement of the ball as a function of Δt:

$$\Delta y = v_{0y}\Delta t - \tfrac{1}{2}g(\Delta t)^2$$

or, because $v_{0y} = v_0\sin\theta_0$,

$$\Delta y = (v_0\sin\theta_0)\Delta t - \tfrac{1}{2}g(\Delta t)^2$$

Because the y-component doesn't change on impact with the wall, the same equation for Δy applies for the entire motion of the ball. Substitute numerical values to obtain:

$$\Delta y = (14\,\text{m/s})(\sin 45°)\Delta t - \tfrac{1}{2}(9.81\,\text{m/s}^2)(\Delta t)^2$$

When the ball hits the ground, $\Delta y = -2.0$ m and $\Delta t = t_{\text{flight}}$:

$$-2.0\,\text{m} = (14\,\text{m/s})(\sin 45°)t_{\text{flight}} - \tfrac{1}{2}(9.81\,\text{m/s}^2)t_{\text{flight}}^2$$

Using the quadratic formula or your graphing calculator, solve for the time of flight:

$$t_{\text{flight}} = 2.203\,\text{s}$$

The horizontal distance traveled in this time is given by:

$$\Delta x = (v_{0x}\cos\theta_0)t_{\text{flight}}$$

Substitute numerical values and evaluate Δx:

$$\Delta \boldsymbol{x} = (14\,\text{m/s})(\cos 45°)(2.203\,\text{s}) = 21.8\,\text{m}$$

Use equation (1) to find where the ball hits the ground:

$$x' = 21.8\,\text{m} - 4.0\,\text{m} = \boxed{18\text{m}}$$

(b) The time-to-the-wall, Δt_{wall}, is related to the displacement of the ball when it hits the wall and to the x component of its velocity:

$$\Delta t_{\text{wall}} = \frac{\Delta x_{\text{wall}}}{v_{0x}} = \frac{\Delta x_{\text{wall}}}{v_0\cos\theta_0}$$

Substitute numerical values and evaluate Δt_{wall}:

$$\Delta t_{\text{wall}} = \frac{4.0\,\text{m}}{(14\,\text{m/s})\cos 45°} = 0.4041\,\text{s} = \boxed{0.40\,\text{s}}$$

(c) First we'll find the y component of the ball's velocity when it hits the wall. Use a constant-acceleration equation to express $v_y(\Delta t_{\text{wall}})$:

$$v_y(\Delta t_{\text{wall}}) = v_{0y} + a_y\Delta t_{\text{wall}}$$

or, because $v_{0y} = v_0\sin\theta_0$ and $a_y = -g$,

$$v_y(\Delta t_{\text{wall}}) = v_0\sin\theta_0 - g\Delta t_{\text{wall}}$$

Substitute numerical values and evaluate $v_y(0.4041\text{ s})$:

$$v_y(0.4041\,\text{s}) = (14\,\text{m/s})\sin 45° - (9.81\,\text{m/s}^2)(0.4041\,\text{s}) = 5.935\,\text{m/s}$$

Now we need to find the height of the ball when it hit the wall. Use a constant-acceleration equation to express $y(\Delta t_{\text{wall}})$:

$$y(\Delta t_{\text{wall}}) = y_0 + v_{0y}\Delta t_{\text{wall}} + \tfrac{1}{2}a_y(\Delta t_{\text{wall}})^2$$

Because $v_{0y} = v_0\sin\theta_0$ and $a_y = -g$:

$$y(\Delta t_{\text{wall}}) = y_0 + (v_0\sin\theta_0)\Delta t_{\text{wall}} - \tfrac{1}{2}g(\Delta t_{\text{wall}})^2$$

Substitute numerical values and evaluate $y(0.4041\text{ s})$:

$$\begin{aligned} y(0.4041\,\text{s}) &= 2.0\,\text{m} + (14\,\text{m/s})(\sin 45°)(0.4041\,\text{s}) - \tfrac{1}{2}(9.81\,\text{m/s}^2)(0.4041\,\text{s})^2 \\ &= 5.199\,\text{m} = \boxed{5.2\,\text{m}} \end{aligned}$$

(*d*) Letting Δt_{after} represent the time the ball is in the air after its collision with the wall, express its vertical position as a function of time:

$$y(\Delta t_{\text{after}}) = y_0 + v_y(0.4041\,\text{s})\Delta t_{\text{after}} - \tfrac{1}{2}g(\Delta t_{\text{after}})^2$$

Noting that $y(\Delta t_{\text{after}}) = 0$ when the ball hits the ground, substitute numerical values to obtain:

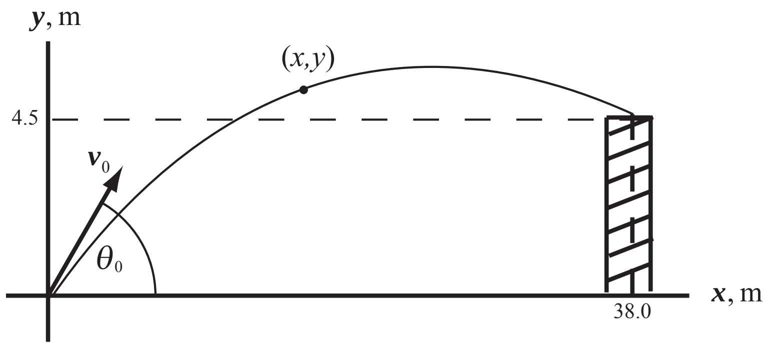
$$0 = 5.199\,\text{m} + (5.935\,\text{m/s})\Delta t_{\text{after}} - \tfrac{1}{2}(9.81\,\text{m/s}^2)(\Delta t_{\text{after}})^2$$

Solving this equation using the quadratic formula or your graphing calculator yields:

$$\Delta t_{\text{after}} = 1.798\,\text{s} = \boxed{1.8\,\text{s}}$$

101 ••• Catapults date from thousands of years ago, and were used historically to launch everything from stones to horses. During a battle in what is now Bavaria, inventive artillerymen from the united German clans launched giant *spaetzle* from their catapults toward a Roman fortification whose walls were 8.50 m high. The catapults launched *spaetzle* projectiles from a height of 4.00 m above the ground, and 38.0 m from the walls of the fortification, at an angle of 60.0 degrees above the horizontal. (Figure 3-41.) If the projectiles were to impact the top of the wall, splattering the Roman soldiers atop the wall with pulverized pasta, (*a*) what launch speed was necessary? (*b*) How long was the spaetzle in the air? (*c*) At what speed did the projectiles hit the wall? Ignore any effects due to air resistance.

Picture the Problem The simplest solution for this problem is to consider the equation relating y and x along the projectile's trajectory that is found in equation 3-17. This equation is valid for trajectories which begin at the origin. We'll let the origin of coordinates be the point of launch (as shown in the diagram). Thus the impact point on top of the walls is y = 4.50 m, rather than 8.50 m. Our launch angle θ_0 is 60.0°, and the position of the center of the wall is 38.0 m. We can solve Equation 3-17 for the launch speed.



(*a*) Equation 3-17 is:

$$y(x) = (\tan\theta_0)x - \left(\frac{g}{2v_0^2\cos^2\theta_0}\right)x^2$$

Solving for v_0 yields:

$$v_0 = \frac{x}{\cos\theta_0}\sqrt{\frac{g}{2[x\tan\theta_0 - y(x)]}}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \frac{38.0\text{ m}}{\cos 60.0°}\sqrt{\frac{9.81\text{ m/s}^2}{2[(38.0\text{ m})\tan 60.0° - 4.50\text{ m}]}} = 21.50\text{ m/s} = \boxed{21.5\text{ m/s}}$$

(*b*) Relate the x component of the spaetzle's velocity to its time-of-flight:

$$t_{\text{flight}} = \frac{\Delta x}{v_{0x}} = \frac{\Delta x}{v_0\cos\theta_0}$$

Substitute numerical values and evaluate t_{flight}:

$$t_{\text{flight}} = \frac{38.0\text{ m}}{(21.50\text{ m/s})\cos 60.0°} = 3.535\text{ s}$$
$$= \boxed{3.53\text{ s}}$$

(*c*)The speed with which the projectiles hit the wall is related to its x and y components through the Pythagorean Theorem:

$$v = \sqrt{v_x^2 + v_y^2} \qquad (1)$$

Because the acceleration in the x direction is zero, the x component of the projectile's velocity on impact equals its initial x component:

$$v_x = v_{0x} = v_0 \cos\theta_0$$

Substitute numerical values and evaluate v_x:

$$v_x = (21.5\ \text{m/s})\cos 60.0° = 10.75\ \text{m/s}$$

Use a constant-acceleration equation to express the y component of the projectile's velocity at any time along its flight path:

$$v_y(t) = v_{0y} + a_y t$$

or, because $v_{0y} = v_0\sin\theta_0$ and $a_y = -g$,

$$v_y(t) = v_0 \sin\theta_0 - gt$$

Substitute numerical values and evaluate $v_y(3.535\ \text{s})$:

$$v_y(3.535\ \text{s}) = (21.5\ \text{m/s})\sin 60.0° - (9.81\ \text{m/s}^2)(3.535\ \text{s}) = -16.06\ \text{m/s}$$

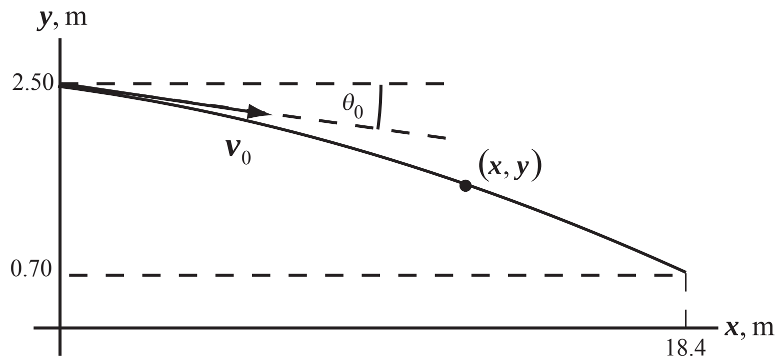
Substitute numerical values for v_x and v_y in equation (1) and evaluate v:

$$v = \sqrt{(10.75\ \text{m/s})^2 + (-16.06\ \text{m/s})^2} = \boxed{19.3\ \text{m/s}}$$

Hitting Targets and Related Problems

102 ••• **[SSM]** The distance from the pitcher's mound to home plate is 18.4 m. The mound is 0.20 m above the level of the field. A pitcher throws a fastball with an initial speed of 37.5 m/s. At the moment the ball leaves the pitcher's hand, it is 2.30 m above the mound. (*a*) What should the angle between $\vec{v}_0$ and the horizontal be so that the ball crosses the plate 0.70 m above ground? (Ignore any effects due to air resistance.) (*b*) With what speed does the ball cross the plate?

Picture the Problem The acceleration of the ball is constant (zero horizontally and $-g$ vertically) and the vertical and horizontal components are independent of each other. Choose the coordinate system shown in the figure and use constant-acceleration equations to express the x and y coordinates of the ball along its trajectory as functions of time. Eliminating t between these equations will lead to an equation that can be solved for θ_0. Differentiating the x and y coordinate equations with respect to time will yield expressions for the instantaneous speed of the ball along its trajectory that you can use to find its speed as it crosses the plate.



(*a*) Express the horizontal and vertical positions of the ball as functions of time:

$$x = (v_0 \cos\theta_0)t \quad (1)$$

and

$$y = y_0 + (v_0 \sin\theta_0)t - \tfrac{1}{2}gt^2 \quad (2)$$

Eliminating t between these equations gives:

$$y = y_0 - (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2$$

When the ball crosses the plate:

$$0.70\text{ m} = 2.50\text{ m} - (\tan\theta_0)(18.4\text{ m}) - \frac{9.81\text{ m/s}^2}{2(37.5\text{ m/s})^2\cos^2\theta_0}(18.4\text{ m})^2$$

Simplifying yields:

$$\frac{1}{\cos^2\theta_0} + 15.58\tan\theta_0 = 1.524$$

Use your graphing calculator to find the magnitude of θ_0:

$$\theta_0 = 1.922° = \boxed{1.9°}$$

(*b*) The speed with which the ball crosses the plate is related to the x and y components of its speed through the Pythagorean Theorem:

$$v = \sqrt{v_x^2 + v_y^2} \quad (3)$$

The x- and y-components of the speed of the ball are given by:

$$v_x = v_0\cos\theta_0$$

and

$$v_y = v_0\sin\theta_0 - gt$$

Substituting for v_x and v_y and simplifying yields:

$$v = \sqrt{(v_0\cos\theta_0)^2 + (v_0\sin\theta_0 - gt)^2}$$
$$= v_0^2 - (2v_0\sin\theta_0 - gt)gt$$

From equation (1), the time required for the ball to reach home plate is:

$$t_{\text{to plate}} = \frac{x_{\text{to plate}}}{v_0 \cos\theta_0}$$

Substitute numerical values and evaluate $gt_{\text{to plate}}$:

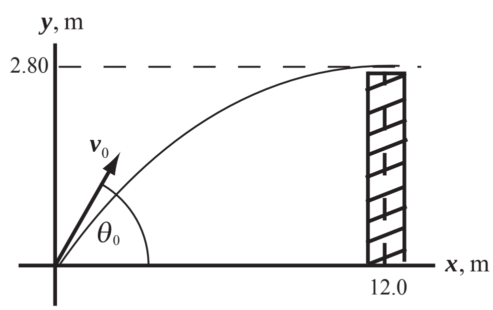
$$t_{\text{to plate}} = \frac{(9.81\ \text{m/s}^2)(18.4\ \text{m})}{(37.5\ \text{m/s})\cos 1.922°}$$
$$= 4.816\ \text{m/s}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(37.5\ \text{m/s})^2 - [2(37.5\ \text{m/s})\sin 1.922° - 4.186\ \text{m/s}](4.186\ \text{m/s})}$$
$$= \boxed{38\ \text{m/s}}$$

103 ••• You are watching your friend play hockey. In the course of the game, he strikes the puck is struck in such a way that, when it is at its highest point, it just clears the surrounding 2.80-m-high Plexiglas wall that is 12.0 m away. Find (*a*) the vertical component of its initial velocity, (*b*) the time it takes to reach the wall, and (*c*) the horizontal component of its initial velocity, its initial speed and angle. Ignore any effects due to air resistance.

Picture the Problem The acceleration of the puck is constant (zero horizontally and $-g$ vertically) and the vertical and horizontal components are independent of each other. Choose a coordinate system with the origin at the point of contact with the puck and the coordinate axes as shown in the figure and use constant-acceleration equations to relate the variables v_{0y}, the time t to reach the wall, v_{0x}, v_0, and θ_0.



(*a*) Using a constant-acceleration equation for the motion in the y direction, express v_{0y} as a function of the puck's displacement Δy:

$$v_y^2 = v_{0y}^2 + 2a_y\Delta y$$
or, because $v_y = 0$ and $a_y = -g$,
$$0 = v_{0y}^2 - 2g\Delta y$$

Solve for v_{0y} to obtain:

$$v_{0y} = \sqrt{2g\Delta y}$$

Substitute numerical values and evaluate v_{0y}:

$$v_{0y} = \sqrt{2(9.81\text{m/s}^2)(2.80\,\text{m})}$$
$$= 7.412\ \text{m/s} = \boxed{7.41\,\text{m/s}}$$

(*b*) The time to reach the top of the wall is related to the initial velocity in the *y* direction:

$$\Delta t = \frac{v_{0y}}{g}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{7.412\,\text{m/s}}{9.81\,\text{m/s}^2} = 0.7555\,\text{s} = \boxed{0.756\text{ s}}$$

(*c*) Use the definition of average velocity to express v_{0x}:

$$v_{0x} = v_x = \frac{\Delta x}{\Delta t}$$

Substitute numerical values and evaluate v_{0x}:

$$v_{0x} = \frac{12.0\,\text{m}}{0.7555\,\text{s}} = 15.88\,\text{m/s} = \boxed{15.9\,\text{m/s}}$$

v_0 is given by:

$$v_0 = \sqrt{v_{0x}^2 + v_{0y}^2}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{(15.88\,\text{m/s})^2 + (7.412\,\text{m/s})^2} = \boxed{17.5\,\text{m/s}}$$

θ_0 is related to v_{0y} and v_{0x}:

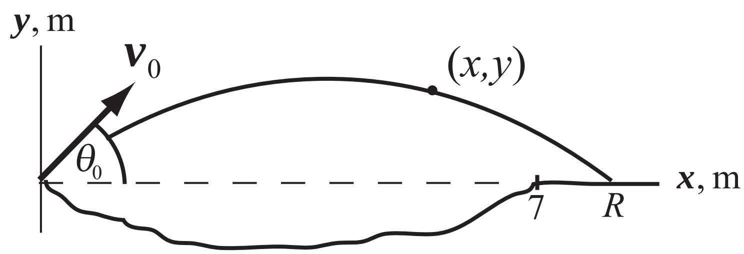
$$\theta_0 = \tan^{-1}\left(\frac{v_{0y}}{v_{0x}}\right)$$

Substitute numerical values and evaluate θ_0 :

$$\theta_0 = \tan^{-1}\left(\frac{7.412\,\text{m/s}}{15.88\,\text{m/s}}\right) = \boxed{25.0°}$$

104 ••• Carlos is on his trail bike, approaching a creek bed that is 7.0 m wide. A ramp with an incline of 10º has been built for daring people who try to jump the creek. Carlos is traveling at his bike's maximum speed, 40 km/h. (*a*) Should Carlos attempt the jump or brake hard? (*b*) What is the minimum speed a bike must have to make this jump? Assume equal elevations on either side of the creek. Ignore any effects of air resistance.

Picture the Problem In the absence of air resistance, the acceleration of Carlos and his bike is constant and we can use constant-acceleration equations to express his *x* and *y* coordinates as functions of time. Eliminating the parameter *t* between these equations will yield *y* as a function of *x* … an equation we can use to decide whether he can jump the creek bed as well as to find the minimum speed required to make the jump.



(a) Use a constant-acceleration equation to express Carlos' horizontal position as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta_0$, and $a_x = 0$,

$$x = (v_0\cos\theta_0)t$$

Use a constant-acceleration equation to express Carlos' vertical position as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

Because $y_0 = 0$, $v_{0y} = v_0\sin\theta_0$, and $a_y = -g$:

$$y = (v_0\sin\theta_0)t - \tfrac{1}{2}gt^2$$

Eliminate t between the x- and y-equations to obtain:

$$y = (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2$$

Substitute $y = 0$ and $x = R$ to obtain:

$$0 = (\tan\theta_0)R - \frac{g}{2v_0^2\cos^2\theta_0}R^2$$

Solving for R yields:

$$R = \frac{v_0^2}{g}\sin(2\theta_0)$$

Substitute numerical values and evaluate R:

$$R = \frac{\left(40\times10^3\ \frac{\text{m}}{\text{h}}\times\frac{1\ \text{h}}{3600\ \text{s}}\right)^2}{9.81\ \text{m/s}^2}\sin 2(10°)$$

$$= 4.3\ \text{m}$$

Because 4.3 m < 7 m, he should apply the brakes!

(b) Solve the equation we used in the previous step for $v_{0,\text{min}}$:

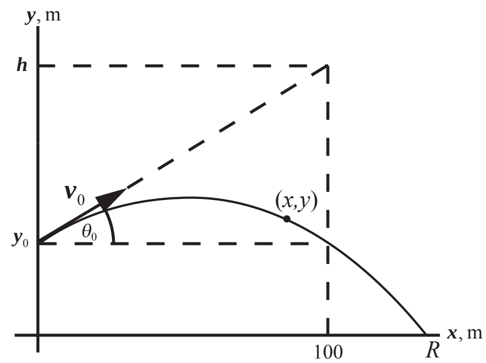
$$v_{0,\text{min}} = \sqrt{\frac{Rg}{\sin(2\theta_0)}}$$

Letting $R = 7$ m, evaluate $v_{0,\min}$:

$$v_{0,\min} = \sqrt{\frac{(7.0\text{ m})(9.81\text{m/s}^2)}{\sin 2(10°)}} = \boxed{14\text{ m/s} = 50\text{ km/h}}$$

105 ••• **[SSM]** If a bullet that leaves the muzzle of a gun at 250 m/s is to hit a target 100 m away at the level of the muzzle (1.7 m above the level ground), the gun must be aimed at a point above the target. (*a*) How far above the target is that point? (*b*) How far behind the target will the bullet strike the ground? Ignore any effects due to air resistance.

Picture the Problem In the absence of air resistance, the bullet experiences constant acceleration along its parabolic trajectory. Choose a coordinate system with the origin at the end of the barrel and the coordinate axes oriented as shown in the figure and use constant-acceleration equations to express the *x* and *y* coordinates of the bullet as functions of time along its flight path.



(*a*) Use a constant-acceleration equation to express the bullet's horizontal position as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta_0$, and $a_x = 0$,

$$x = (v_0\cos\theta_0)t$$

Use a constant-acceleration equation to express the bullet's vertical position as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $v_{0y} = v_0\sin\theta_0$, and $a_y = -g$,

$$y = y_0 + (v_0\sin\theta_0)t - \tfrac{1}{2}gt^2$$

Eliminate *t* between the two equations to obtain:

$$y = y_0 + (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2$$

Because $y = y_0$ when the bullet hits the target:

$$0 = (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2$$

Solve for the angle above the horizontal that the rifle must be fired to hit the target:

$$\theta_0 = \tfrac{1}{2}\sin^{-1}\left(\frac{xg}{v_0^2}\right)$$

Substitute numerical values and evaluate θ_0:

$$\theta_0 = \tfrac{1}{2}\sin^{-1}\left[\frac{(100\,\text{m})(9.81\,\text{m/s}^2)}{(250\,\text{m/s})^2}\right] = 0.450°$$

Note: A second value for θ_0, 89.6° is physically unreasonable.

Referring to the diagram, relate h to θ_0:

$$\tan\theta_0 = \frac{h}{100\,\text{m}} \Rightarrow h = (100\,\text{m})\tan\theta_0$$

Substitute numerical values and evaluate h:

$$h = (100\,\text{m})\tan(0.450°) = \boxed{0.785\,\text{m}}$$

(*b*) The distance Δx behind the target where the bullet will strike the ground is given by:

$$\Delta x = R - 100\text{ m} \qquad (1)$$

where R is the range of the bullet.

When the bullet strikes the ground, $y = 0$ and $x = R$:

$$0 = y_0 + (\tan\theta_0)R - \frac{g}{2v_0^2\cos^2\theta_0}R^2$$

Substitute numerical values and simplify to obtain:

$$\frac{9.81\text{ m/s}^2}{2(250\text{ m/s})^2\cos^2 0.450°}R^2 - (\tan 0.450°)R - 1.7\text{ m} = 0$$

Use the quadratic formula or your graphing calculator to obtain:

$$R = 206\text{ m}$$

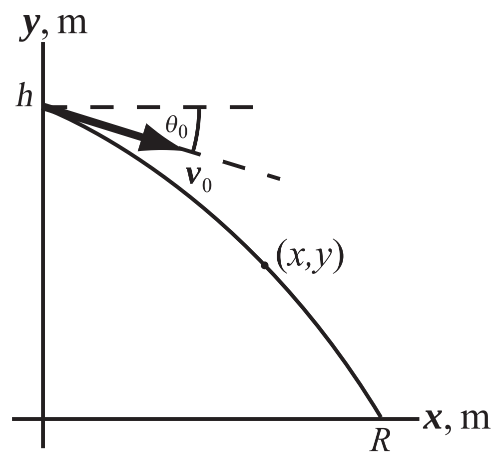
Substitute for R in equation (1) to obtain:

$$\Delta \boldsymbol{x} = 206\text{ m} - 100\text{ m} = \boxed{105\text{ m}}$$

General Problems

106 •• During a do-it-yourself roof repair project, you are on the roof of your house and accidentally drop your hammer. The hammer then slides down the roof at constant speed of 4.0 m/s. The roof makes an angle of 30º with the horizontal, and its lowest point is 10 m from the ground. (*a*) How long after leaving the roof does the hammer hit the ground? (*b*) What is the horizontal distance traveled by the hammer between the instant it leaves the roof and the instant it hits the ground? (Ignore any effects due to air resistance.)

Picture the Problem In the absence of air resistance, the hammer experiences constant acceleration as it falls. Choose a coordinate system with the origin and coordinate axes as shown in the figure and use constant-acceleration equations to describe the x and y coordinates of the hammer along its trajectory. We'll use the equation describing the vertical motion to find the time of flight of the hammer and the equation describing the horizontal motion to determine its range.



(a) Using a constant-acceleration equation, express the x coordinate of the hammer as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta_0$, and $a_x = 0$,

$$x = (v_0 \cos\theta_0)t$$

Using a constant-acceleration equation, express the y coordinate of the hammer as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = h$, $v_{0y} = v_0\sin\theta$, and $a_y = -g$,

$$y = h + (v_0 \sin\theta)t - \tfrac{1}{2}gt^2$$

Substituting numerical values yields:

$$y = 10\,\text{m} + (-4.0\,\text{m/s})(\sin 30°)t - \tfrac{1}{2}(9.81\,\text{m/s}^2)t^2$$

When the hammer hits the ground, $y = 0$ and our equation becomes:

$$0 = 10\,\text{m} - (4.0\,\text{m/s})\sin 30°\, t_{\text{fall}} - \tfrac{1}{2}(9.81\,\text{m/s}^2)t_{\text{fall}}^2$$

Use the quadratic formula or your graphing calculator to solve for the time of fall:

$$t_{\text{fall}} = 1.238\,\text{s} = \boxed{1.2\,\text{s}}$$

(b) Use the x-coordinate equation to express the horizontal distance traveled by the hammer as a function of its time-of-fall:

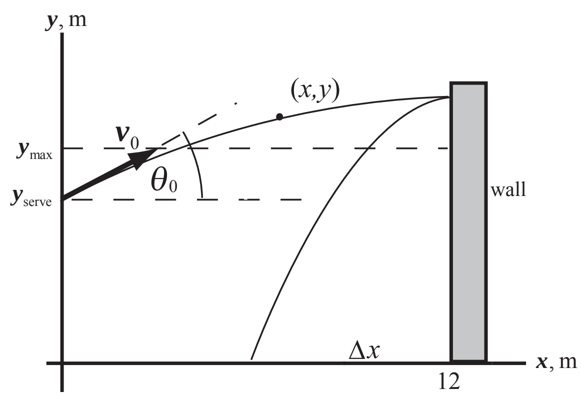
$$R = v_{0x}t_{\text{fall}} = (v_0\cos\theta_0)t_{\text{fall}}$$

Substitute numerical values and evaluate R:

$$R = (4.0\,\text{m/s})(\cos 30°)(1.238\,\text{s})$$
$$= \boxed{4.3\,\text{m}}$$

107 •• A squash ball typically rebounds from a surface with 25% of the speed with which it initially struck the surface. Suppose a squash ball is served in a shallow trajectory, from a height above the ground of 45 cm, at a launch angle of 6.0° degrees above the horizontal, and at a distance of 12 m from the front wall. (*a*) If it strikes the front wall exactly at the top of its parabolic trajectory, determine how high above the floor the ball strikes the wall. (*b*) How far horizontally from the wall does it strike the floor, after rebounding? Ignore any effects due to air resistance.

Picture the Problem The following diagram shows the trajectory of the ball, a coordinate system, and the distances relevant to the solution of the problem. This problem is another variation on the projectile motion problem in which we are given the launch angle and the horizontal distance to the point at which the ball reaches its peak. At that point, the ball's velocity is solely horizontal. In order to answer the question raised in (*b*), we'll need to find the (horizontal) speed with which the ball strikes the wall. We can then use this rebound speed to find the distance Δx by applying appropriate constant-acceleration equations.



(*a*) The height above the floor at which the ball strikes the wall is given by:

$$y_{max} = y_{serve} + h \qquad (1)$$

where h is the height above the service elevation to which the ball rises.

The distance h is related to the time Δt required for the ball to rise to its maximum height:

$$h = \tfrac{1}{2} g(\Delta t)^2 \qquad (2)$$

Δt is also related to v_{0y} and Δx_{serve}:

$$v_{0y} = g\Delta t \Rightarrow \Delta t = \frac{v_{0y}}{g} \qquad (3)$$

and

$$\Delta x_{serve} = v_{0x}\Delta t \Rightarrow \Delta t = \frac{\Delta x_{serve}}{v_{0x}} \qquad (4)$$

Substituting both (3) and (4) in equation (2) yields:

$$h = \tfrac{1}{2} g \left(\frac{v_{0y}}{g} \right) \left(\frac{\Delta x_{\text{serve}}}{v_{0x}} \right)$$

or, because $v_{0y} = v_0 \sin\theta_0$ and $v_{0x} = v_0 \cos\theta_0$,

$$h = \tfrac{1}{2} g \left(\frac{v_0 \sin\theta_0}{g} \right) \left(\frac{\Delta x_{\text{serve}}}{v_0 \cos\theta_0} \right)$$

Simplifying this expression yields:

$$h = \frac{\Delta x_{\text{serve}}}{2} \tan\theta_0$$

Substitute for h in equation (1) to obtain:

$$y_{\max} = y_{\text{serve}} + \frac{\Delta x_{\text{serve}}}{2} \tan\theta_0$$

Substitute numerical values and evaluate $y_{\max}$:

$$y_{\max} = 0.45\ \text{m} + \frac{12\ \text{m}}{2} \tan 6.0° = 1.081\ \text{m}$$

$$= \boxed{1.1\ \text{m}}$$

(*b*) The distance Δx the ball lands away from the wall is given by

$$\Delta x = v_{x,\text{rebound}} \Delta t$$

where Δt is the time it takes for the ball to fall to the floor.

Because the ball rebounds with 25% of the speed with which it initially struck the surface:

$$v_{x,\text{rebound}} = 0.25 v_{0x}$$

and

$$\Delta x = 0.25 v_{0x} \Delta t \qquad (5)$$

Δt is related to distance the ball falls vertically before hitting the floor:

$$y_{\max} = \tfrac{1}{2} g (\Delta t)^2 \Rightarrow \Delta t = \sqrt{\frac{2 y_{\max}}{g}}$$

Substitute for Δt in equation (5) to obtain:

$$\Delta x = 0.25 v_{0x} \sqrt{\frac{2 y_{\max}}{g}} \qquad (6)$$

To find v_{0x}, equate equations (3) and (4):

$$\frac{v_{0y}}{g} = \frac{\Delta x_{\text{serve}}}{v_{0x}} \qquad (7)$$

From the diagram, we can see that:

$$v_{0y} = v_{0x} \tan\theta_0$$

Substituting for v_{0y} in equation (7) yields:

$$\frac{v_{0x} \tan\theta_0}{g} = \frac{\Delta x_{\text{serve}}}{v_{0x}}$$

Solving for v_{0x} yields:

$$v_{0x} = \sqrt{\frac{g\Delta x_{\text{serve}}}{\tan\theta_0}}$$

Substitute for v_{0x} in equation (6) to obtain:

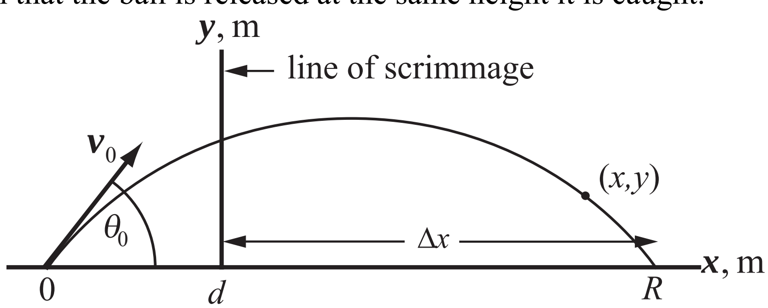
$$\Delta x = 0.25\sqrt{\frac{g\Delta x_{\text{serve}}}{\tan\theta_0}}\sqrt{\frac{2y_{\max}}{g}} = 0.25\sqrt{\frac{2\Delta x_{\text{serve}}y_{\max}}{\tan\theta_0}}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = 0.25\sqrt{\frac{2(12\text{ m})(1.081\text{ m})}{\tan 6.0°}} = \boxed{3.9\text{ m}}$$

108 •• A football quarterback throws a pass at an angle of 36.5° above the horizontal. He releases the pass 3.50 m behind the line of scrimmage. His receiver left the line of scrimmage 2.50 s earlier, goes straight downfield at a constant speed of 7.50 m/s. In order that the pass land gently in the receiver's hands without the receiver breaking stride, with what speed must the quarterback throw the pass? Assume that the ball is released at the same height it is caught and that the receiver is straight downfield from the quarterback at the time of the release. Ignore any effects due to air resistance.

Picture the Problem This problem deals with a moving target being hit by a projectile. The range required for the projectile is simply the distance that the receiver runs by the time the ball lands in his hands. We can use the equations developed in the text for both the range and time of flight of a projectile for any value of launch speed and angle, provided the launch and landing occur at the same height. The following diagram shows a convenient choice of a coordinate system as well as the trajectory of the ball. Note that the diagram includes the assumption that the ball is released at the same height it is caught.



The distance the receiver runs is given by:

$$\Delta x = v_{\text{rec}}\Delta t_{\text{tot}} \qquad (1)$$

The time-of-flight of the ball is given by:

$$\Delta t_{\text{ball}} = \Delta t_{\text{tot}} - \Delta t_{\text{delay}} \qquad (2)$$

where Δt_{delay} is the time the receiver ran before the quarterback released the ball.

The same-elevation range of the ball is:

$$R = \frac{v_0^2}{g}\sin 2\theta_0 \qquad (3)$$

If d is the distance behind the line of scrimmage that the ball is released:

$$R = \Delta x + d \qquad (4)$$

Combine equations (1), (3) and (4) to obtain:

$$v_{\text{rec}}\Delta t_{\text{tot}} + d = \frac{v_0^2}{g}\sin 2\theta_0$$

Solving for Δt_{tot} yields:

$$\Delta t_{\text{tot}} = \frac{v_0^2}{g v_{\text{rec}}}\sin 2\theta_0 - \frac{d}{v_{\text{rec}}}$$

The time-of-flight of the ball is given by:

$$\Delta t_{\text{ball}} = \frac{2v_0}{g}\sin\theta_0$$

Substitute for Δt_{tot} and Δt_{ball} in equation (2) to obtain:

$$\frac{2v_0}{g}\sin\theta_0 = \frac{v_0^2}{g v_{\text{rec}}}\sin 2\theta_0 - \Delta t_{\text{delay}} - \frac{d}{v_{\text{rec}}}$$

Rearrange and simplify to obtain:

$$\frac{\sin 2\theta_0}{g v_{\text{rec}}}v_0^2 - \frac{2\sin\theta_0}{g}v_0 - \Delta t_{\text{delay}} - \frac{d}{v_{\text{rec}}} = 0$$

Substituting numerical values yields:

$$\frac{\sin 2(36.5^\circ)}{(9.81\,\text{m/s}^2)(7.50\,\text{m/s})}v_0^2 - \frac{2\sin 36.5^\circ}{9.81\,\text{m/s}^2}v_0 - 2.50\,\text{s} - \frac{3.50\,\text{m}}{7.50\,\text{m/s}} = 0$$

or

$$\left(0.0130\,\frac{\text{s}^3}{\text{m}^2}\right)v_0^2 - \left(0.1213\,\frac{\text{s}^2}{\text{m}}\right)v_0 - 2.967\,\text{s} = 0$$

Use the quadratic formula or your graphing calculator to obtain:

$$v_0 = -11.1\,\text{m/s or } 20.5\,\text{m/s}$$

and, because the negative throwing speed is not physical,

$$v_0 = \boxed{20.5\,\text{m/s}}$$

109 •• Suppose a test pilot is able to safely withstand an acceleration of up to 5.0 times the acceleration due to gravity (that is, remain conscious and alert enough to fly). In the course of maneuvers, he is required to fly the plane in a horizontal circle at its top speed of 1900 mi/h, (*a*) What is the radius of the smallest circle he will be able to safely fly the plane in? (*b*) How long does it take him to go halfway around this minimum-radius circle?

Picture the Problem This is a simple application of centripetal acceleration.

(*a*) Express the radius of the pilot's circular path:

$$r = \frac{v^2}{a_c}$$

or, because $a_c = 5.0g$,

$$r = \frac{v^2}{5.0g}$$

Substitute numerical values and evaluate r:

$$r = \frac{\left(1900\,\frac{\text{mi}}{\text{h}} \times 1609\,\frac{\text{m}}{\text{mi}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{5.0\left(9.81\,\text{m/s}^2\right)}$$

$$= 14.70\,\text{km} = \boxed{15\,\text{km}}$$

(*b*) The time required to reverse his direction is equal to one-half the period of his motion:

$$t_{\text{rev}} = \tfrac{1}{2}T = \frac{2\pi r}{2v} = \frac{\pi r}{v}$$

Substitute numerical values and evaluate t_{rev}:

$$t_{\text{rev}} = \frac{\pi(14.70\,\text{km})}{1900\,\frac{\text{mi}}{\text{h}} \times 1609\,\frac{\text{m}}{\text{mi}} \times \frac{1\,\text{h}}{3600\,\text{s}}}$$

$$= \boxed{54\,\text{s}}$$

110 •• A particle moves in the *xy* plane with constant acceleration. At $t = 0$ the particle is at $\vec{r}_1 = (4.0\text{ m})\hat{i} + (3.0\text{ m})\hat{j}$, with velocity $\vec{v}_1$. At $t = 2.0$ s, the particle has moved to $\vec{r}_2 = (10\text{ m})\hat{i} - (2.0\text{ m})\hat{j}$ and its velocity has changed to $\vec{v}_2 = (5.0\text{ m/s})\hat{i} - (6.0\text{ m/s})\hat{j}$. (*a*) Find $\vec{v}_1$. (*b*) What is the acceleration of the particle? (*c*) What is the velocity of the particle as a function of time? (*d*) What is the position vector of the particle as a function of time?

Picture the Problem Because the acceleration is constant; we can use the constant-acceleration equations in vector form and the definitions of average velocity and average (instantaneous) acceleration to solve this problem.

(*a*) The average velocity is given by:

$$\vec{\boldsymbol{v}}_{av} = \frac{\Delta\vec{\boldsymbol{r}}}{\Delta t} = \frac{\vec{\boldsymbol{r}}_2 - \vec{\boldsymbol{r}}_1}{\Delta t}$$
$$= (3.0\ \text{m/s})\hat{\boldsymbol{i}} + (-2.5\ \text{m/s})\hat{\boldsymbol{j}}$$

The average velocity can also be expressed as:

$$\vec{\boldsymbol{v}}_{av} = \frac{\vec{\boldsymbol{v}}_1 + \vec{\boldsymbol{v}}_2}{2} \Rightarrow \vec{v}_1 = 2\vec{v}_{av} - \vec{v}_2$$

Substitute numerical values to obtain:

$$\vec{\boldsymbol{v}}_1 = \boxed{(1.0\ \text{m/s})\hat{\boldsymbol{i}} + (1.0\ \text{m/s})\hat{\boldsymbol{j}}}$$

(*b*) The acceleration of the particle is given by:

$$\vec{\boldsymbol{a}} = \frac{\Delta\vec{\boldsymbol{v}}}{\Delta t} = \frac{\vec{\boldsymbol{v}}_2 - \vec{\boldsymbol{v}}_1}{\Delta t}$$
$$= \boxed{(2.0\ \text{m/s}^2)\hat{\boldsymbol{i}} + (-3.5\ \text{m/s}^2)\hat{\boldsymbol{j}}}$$

(*c*) The velocity of the particle as a function of time is:

$$\vec{\boldsymbol{v}}(t) = \vec{\boldsymbol{v}}_1 + \vec{\boldsymbol{a}}t = \boxed{[(1.0\ \text{m/s}) + (2.0\ \text{m/s}^2)t]\hat{\boldsymbol{i}} + [(1.0\ \text{m/s}) + (-3.5\ \text{m/s}^2)t]\hat{\boldsymbol{j}}}$$

(*d*) Express the position vector as a function of time:

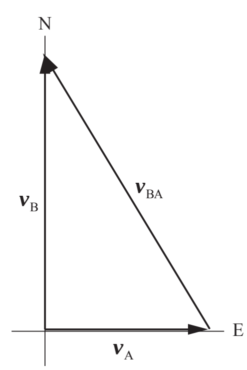
$$\vec{\boldsymbol{r}}(t) = \vec{\boldsymbol{r}}_1 + \vec{\boldsymbol{v}}_1 t + \tfrac{1}{2}\vec{\boldsymbol{a}}t^2$$

Substitute numerical values and evaluate $\vec{\boldsymbol{r}}(t)$:

$$\vec{\boldsymbol{r}}(t) = \boxed{\begin{array}{l}[(4.0\ \text{m}) + (1.0\ \text{m/s})t + (1.0\ \text{m/s}^2)t^2]\hat{\boldsymbol{i}} \\ \qquad + [(3.0\ \text{m}) + (1.0\ \text{m/s})t + \left(-1.8\ \text{m/s}^2\right)t^2]\hat{\boldsymbol{j}}\end{array}}$$

111 •• [SSM] Plane A is headed due east, flying at an air speed of 400 mph. Directly below, at a distance of 4000 ft, plane B is headed due north, flying at an air speed of 700 mph. Find the velocity vector of plane B relative to A.

Picture the Problem Choose a coordinate system in which the +*x* axis is to the east and the +*y* axis is to the north and write the velocity vectors for the two airplanes using unit vector notation. The velocity vectors of the two planes and the velocity vector of plane B relative to plane A is shown in the vector diagram.



The velocity of plane B relative to plane A is given by:

$$\vec{\boldsymbol{v}}_B = \vec{\boldsymbol{v}}_A + \vec{\boldsymbol{v}}_{BA}$$

Solving for $\vec{v}_{\text{BA}}$ gives:

$$\vec{v}_{\text{BA}} = \vec{v}_{\text{B}} - \vec{v}_{\text{A}}$$

Using unit vector notation, write expressions for $\vec{v}_{\text{Bg}}$ and $\vec{v}_{\text{Ag}}$:

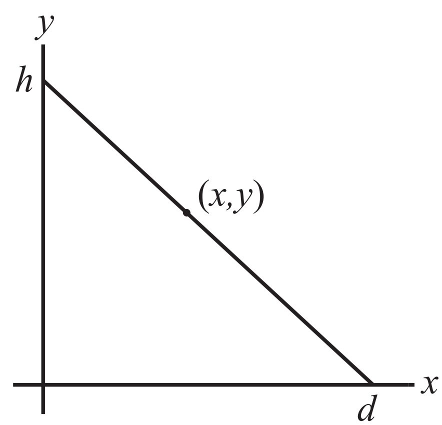
$$\vec{v}_{\text{B}} = (700\ \text{mi/h})\,\hat{\boldsymbol{j}}$$
and
$$\vec{v}_{\text{A}} = (400\ \text{mi/h})\,\hat{\boldsymbol{i}}$$

Substitute for $\vec{v}_{\text{Ba}}$ and $\vec{v}_{\text{Aa}}$ in equation (1) to obtain:

$$\vec{v}_{\text{BA}} = (700\ \text{mi/h})\,\hat{\boldsymbol{j}} - (400\ \text{mi/h})\,\hat{\boldsymbol{i}}$$
$$= \boxed{(-400\ \text{mi/h})\,\hat{\boldsymbol{i}} + (700\ \text{mi/h})\,\hat{\boldsymbol{j}}}$$

112 •• A diver steps off the cliffs at Acapulco, Mexico 30.0 m above the surface of the water. At that moment, he activates his rocket-powered backpack horizontally, which gives him a constant horizontal acceleration of 5.00 m/s^2 but does not affect his vertical motion. (*a*) How long does he take to reach the surface of the water? (*b*) How far out from the base of the cliff does he enter the water, assuming the cliff is vertical? (*c*) Show that his flight path is a straight line.

Picture the Problem Choose a coordinate system in which the origin is at the base of the cliff, the positive *x* axis is to the right, and the positive *y* axis is upward. Let the height of the cliff be *h* and the distance from the bottom of the cliff where the diver hits the water be *d.* Use constant-acceleration equations to obtain expressions for the *x* and *y* coordinates of the diver along his flight path, shown here as a straight line.



(*a*) Using a constant-acceleration equation, relate the vertical position of the diver to his initial position, initial speed, acceleration, and time of fall:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$
or, because $y_0 = h$, $v_{0y} = 0$, and $a_y = -g$,
$$y = h - \tfrac{1}{2}g t^2 \qquad (1)$$

When the diver reaches the surface of the water, $y = 0$ and:

$$0 = h - \tfrac{1}{2}g t^2 \Rightarrow t = \sqrt{\frac{2h}{g}} \qquad (2)$$

Substitute numerical values and evaluate *t*:

$$t = \sqrt{\frac{2(30.0\ \text{m})}{9.81\ \text{m/s}^2}} = \boxed{2.47\ \text{s}}$$

(*b*) Using a constant-acceleration equation, relate the horizontal position of the diver to his initial position, initial speed, acceleration, and time of fall:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$ and $v_{0x} = 0$,

$$x = \tfrac{1}{2}a_x t^2 \qquad (3)$$

When the diver hits the water, his x coordinate is d and the time is given by equation (2):

$$d = \tfrac{1}{2}a_x \frac{2h}{g} = \frac{a_x h}{g}$$

Substitute numerical values and evaluate d:

$$d = \frac{(5.00\ \text{m/s}^2)(30.0\ \text{m})}{9.81\ \text{m/s}^2} = \boxed{15.3\ \text{m}}$$

(*c*) Solving equation (3) for t^2 yields:

$$t^2 = \frac{2x}{a_x}$$

Substitute for t in equation (1) to obtain:

$$y = h - \tfrac{1}{2}g\frac{2x}{a_x} = h - \frac{g}{a_x}x$$

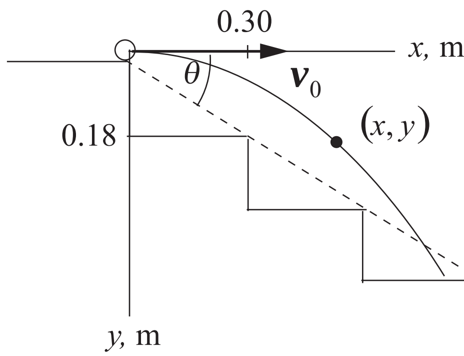
or

$$y = -\frac{g}{a_x}x + h \qquad (4)$$

Because equation (4) is of the form $y = mx + b$, the diver's trajectory into the water is a straight line.

113 •• [**SSM**] A small steel ball is projected horizontally off the top of a long flight of stairs. The initial speed of the ball is 3.0 m/s. Each step is 0.18 m high and 0.30 m wide. Which step does the ball strike first?

Picture the Problem In the absence of air resistance; the steel ball will experience constant acceleration. Choose a coordinate system with its origin at the initial position of the ball, the $+x$ direction to the right, and the $+y$ direction downward. In this coordinate system $y_0 = 0$ and $a = g$. Letting (x, y) be a point on the path of the ball, we can use constant-acceleration equations to express both x and y as functions of time and, using the geometry of the staircase, find an expression for the time of flight of the ball. Knowing its time of flight, we can find its range and identify the step it strikes first.



The angle of the steps, with respect to the horizontal, is:

$$\theta = \tan^{-1}\left(\frac{0.18\,\text{m}}{0.30\,\text{m}}\right) = 31.0°$$

Using a constant-acceleration equation, express the x coordinate of the steel ball in its flight:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_{0x} = 0$ and $a_x = 0$,

$$x = v_{0x}t = v_0 t \qquad (1)$$

Using a constant-acceleration equation, express the y coordinate of the steel ball in its flight:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $v_{0y} = 0$, and $a_y = g$,

$$y = \tfrac{1}{2}gt^2$$

The equation of the dashed line in the figure is:

$$\frac{y}{x} = \tan\theta = \frac{gt}{2v_0} \Rightarrow t = \frac{2v_0}{g}\tan\theta$$

Substitute for t in equation (1) to find the x coordinate of the landing position:

$$x = v_0 t = v_0\left(\frac{2v_0}{g}\tan\theta\right) = \frac{2v_0^2}{g}\tan\theta$$

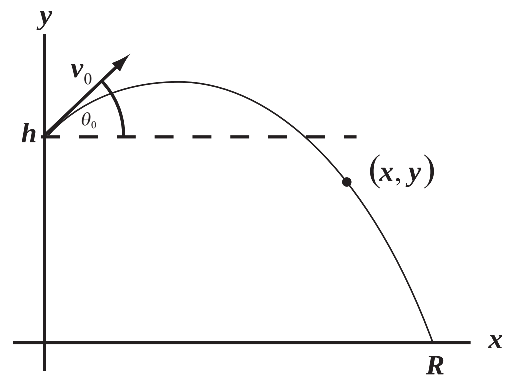
Substitute numerical values and evaluate x:

$$x = \frac{2(3.0\,\text{m/s})^2}{9.81\,\text{m/s}^2}\tan 31° = 1.1\,\text{m} \Rightarrow \text{The}$$

first step with $x > 1.1$ m is the 4th step.

114 •• Suppose you can throw a ball a maximum horizontal distance L when standing on level ground. How far can you throw it from the top of a building of height h if you throw it at (*a*) 0º, (*b*) 30º, (*c*) 45º? Ignore any effects due to air resistance.

Picture the Problem Ignoring the influence of air resistance, the acceleration of the ball is constant once it has left your hand and we can use constant-acceleration equations to express the x and y coordinates of the ball. Elimination of t will yield an equation from which we can determine v_0. We can then use the y equation to express the time of flight of the ball and the x equation to express its range in terms of x_0, v_0, θ and the time of flight.



Use a constant-acceleration equation to express the ball's horizontal position as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta_0$, and $a_x = 0$,

$$x = (v_0\cos\theta_0)t \qquad (1)$$

Use a constant-acceleration equation to express the ball's vertical position as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $v_{0y} = v_0\sin\theta_0$, and $a_y = -g$,

$$y = y_0 + (v_0\sin\theta_0)t - \tfrac{1}{2}gt^2 \qquad (2)$$

Eliminate t between equations (1) and (2) to obtain:

$$y = x_0 + (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2$$

For the throw while standing on level ground we have:

$$0 = (\tan\theta_0)L - \frac{g}{2v_0^2\cos^2\theta_0}L^2$$

and

$$L = \frac{v_0^2}{g}\sin 2\theta_0 = \frac{v_0^2}{g}\sin 2(45°) = \frac{v_0^2}{g}$$

Solving for v_0 gives:

$$v_0 = \sqrt{gL}$$

At impact equation (2) becomes:

$$0 = x_0 + \left(\sqrt{gL}\sin\theta_0\right)t_{\text{flight}} - \tfrac{1}{2}gt_{\text{flight}}^2$$

Solve for the time of flight:

$$t_{\text{flight}} = \sqrt{\frac{L}{g}}\left(\sin\theta_0 + \sqrt{\sin^2\theta_0 + 2}\right)$$

Substitute for v_0 and t_{flight} in equation (1) to express the range of the ball when thrown from an elevation x_0 at an angle θ_0 with the horizontal:

$$R = \left(\sqrt{gL}\cos\theta_0\right)t_{flight} = \left(\sqrt{gL}\cos\theta_0\right)\sqrt{\frac{L}{g}}\left(\sin\theta_0 + \sqrt{\sin^2\theta_0 + 2}\right)$$
$$= L\cos\theta\left(\sin\theta_0 + \sqrt{\sin^2\theta_0 + 2}\right)$$

(*a*) Substitute $\theta = 0°$ and evaluate R: $R(0°) = \boxed{1.41L}$

(*b*) Substitute $\theta = 30°$ and evaluate R: $R(30°) = \boxed{1.73L}$

(*c*) Substitute $\theta = 45°$ and evaluate R: $R(45°) = \boxed{1.62L}$

115 ••• Darlene is a stunt motorcyclist in a traveling circus. For the climax of her show, she takes off from the ramp at angle θ_0, clears a ditch of width L, and lands on an elevated ramp (height h) on the other side (Figure 3-42). (*a*) For a given height h, find the minimum necessary takeoff speed v_{min} needed to make the jump successfully. (*b*) What is v_{min} for $\theta_0 = 30°$, $L = 8.0$ m and $h = 4.0$ m? (*c*) Show that no matter what her takeoff speed, the maximum height of the platform is $h < L\tan\theta_0$. Interpret this result physically. (Neglect any effects due to air resistance and treat the rider and the bike as if they were a single particle.)

Picture the Problem Choose a coordinate system with its origin at the point where the bike becomes airborne and with the positive x direction to the right and the positive y direction upward. With this choice of coordinate system we can relate the x and y coordinates of the rider and bike (which we're treating as a single particle) using Equation 3-17.

(*a*) The path of the motorcycle is given by Equation 3-17:

$$y(x) = (\tan\theta_0)x - \left(\frac{g}{2v_0^2\cos^2\theta_0}\right)x^2$$

For the jump to be successful, $h < y(x)$. Solving for v_0 with $x = L$, we find that:

$$v_{min} > \boxed{\frac{L}{\cos\theta_0}\sqrt{\frac{g}{2(L\tan\theta_0 - h)}}}$$

(*b*) Substitute numerical values and evaluate v_{min}:

$$v_{min} > \frac{8.0\text{ m}}{\cos 30°}\sqrt{\frac{9.81\text{ m/s}^2}{2[(8.0\text{ m})\tan 30° - 4.0\text{ m}]}} = \boxed{26\text{ m/s}}$$

(*c*) In order for our expression for v_{min} to be real valued; that is, to predict values for v_{min} that are physically meaningful, $L\tan\theta_0 - h > 0$. Hence $h < L\tan\theta_0$.

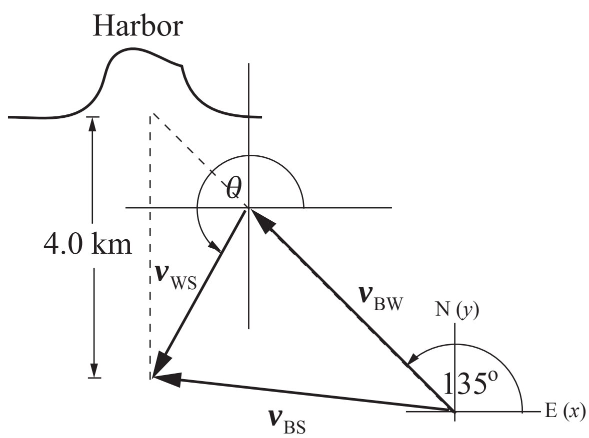
The interpretation is that the bike "falls away" from traveling on a straight-line path due to the free-fall acceleration downward. No matter what the initial speed of the bike, it must fall a little bit before reaching the other side of the ditch.

116 ••• A small boat is headed for a harbor 32 km directly northwest of its current position when it is suddenly engulfed in heavy fog. The captain maintains a compass bearing of northwest and a speed of 10 km/h relative to the water. The fog lifts 3.0 h later and the captain notes that he is now exactly 4.0 km south of the harbor. (*a*) What was the average velocity of the current during those 3.0 h? (*b*) In what direction should the boat have been heading to reach its destination along a straight course? (*c*) What would its travel time have been if it had followed a straight course?

Picture the Problem Let the origin be at the position of the boat when it was engulfed by the fog. Take the *x* and *y* directions to be east and north, respectively. Let $\vec{v}_{BW}$ be the velocity of the boat relative to the water, $\vec{v}_{BS}$ be the velocity of the boat relative to the shore, and $\vec{v}_{WS}$ be the velocity of the water with respect to the shore. Then

$$\vec{v}_{BS} = \vec{v}_{BW} + \vec{v}_{WS}.$$

θ is the angle of $\vec{v}_{WS}$ with respect to the *x* (east) direction.



(*a*) The position of the boat at $t = 3.0$ h is:

$$\begin{aligned}\vec{r}_{\text{boat}} &= [(32\text{ km})(\cos 135°)]\hat{\boldsymbol{i}} + [(32\text{ km})(\sin 135°) - 4.0\text{ km}]\hat{\boldsymbol{j}} \\ &= (-22.63\text{ km})\hat{\boldsymbol{i}} + (18.63\text{ km})\hat{\boldsymbol{j}}\end{aligned}$$

The coordinates of the boat at $t = 3.0$ h are also given by:

$$r_x = [(10\text{ km/h})\cos 135° + v_{WS}\cos\theta](3.0\text{ h}) = -22.63\text{ km}$$

and

$$r_y = [(10\text{ km/h})\sin 135° + v_{WS}\sin\theta](3.0\text{ h}) = 18.63\text{ km}$$

Solving for $v_{WS}\cos\theta$ and $v_{WS}\sin\theta$ gives:

$$v_{WS}\cos\theta = -0.4723\text{ km/h} \qquad (1)$$

and

$$v_{WS}\sin\theta = -0.8611\text{ km/h} \qquad (2)$$

Divide the second of these equations by the first and solve for θ to obtain:

$$\theta = \tan^{-1}\left(\frac{-0.8611\text{ km/h}}{-0.4723\text{ km/h}}\right) = 61.3° \text{ or } 241.3°$$

One can solve either equation (1) or equation (2) for v_{WS}. Using equation (1) yields:

$$v_{WS} = \frac{-0.4723\text{ km/h}}{\cos\theta}$$

Because the boat has drifted south, use $\theta = 241.3°$ to obtain:

$$v_{WS} = \frac{-0.4723\text{ km/h}}{\cos(241.3°)} = \boxed{0.98\text{ km/h at } \theta = 241°}$$

(*b*) Letting ϕ be the angle between east and the proper heading for the boat, express the components of the velocity of the boat with respect to the shore:

$$v_{BS,x} = (10\text{ km/h})\cos\phi + (0.982\text{ km/h})\cos(241.3°) \qquad (3)$$

and

$$v_{BS,y} = (10\text{ km/h})\sin\phi + (0.982\text{ km/h})\sin(241.3°)$$

For the boat to travel northwest:

$$v_{BS,x} = -v_{BS,y}$$

Substitute the velocity components, square both sides of the equation, and simplify the expression to obtain the equations:

$$\sin\phi + \cos\phi = 0.133 \text{ and}$$

$$\sin^2\phi + \cos^2\phi + 2\sin\phi\cos\phi = 0.0177$$

or

$$1 + \sin(2\phi) = 0.0177$$

Solving for ϕ yields:

$$\phi = \tfrac{1}{2}\sin^{-1}(0.0177 - 1) = -39.6°$$

Because the current pushes south, the boat must head more northerly than 135°:

The correct heading is $\boxed{39.6° \text{ west of north}}$.

(*c*) Substitute for ϕ in equation (3) and evaluate $v_{BS,x}$ to obtain:

$$v_{BS,x} = -6.846\text{ km/h}$$

From the diagram:

$$v_{BS} = \frac{v_{BS,x}}{\cos 135°} = \frac{-6.846\text{ km/h}}{\cos 135°} = 9.681\text{ km/h}$$

To find the time to travel 32 km, divide the distance by the boat's actual speed:

$$t = \frac{32\ \text{km}}{9.681\ \text{km/h}} = \boxed{3.3\,\text{h} \approx 3\,\text{h}\ 18\,\text{min}}$$

117 •• [**SSM**] Galileo showed that, if any effects due to air resistance are neglected, the ranges for projectiles (on a level field) whose angles of projection exceed or fall short of 45º by the same amount are equal. Prove Galileo's result.

Picture the Problem In the absence of air resistance, the acceleration of the projectile is constant and the equation of a projectile for equal initial and final elevations, which was derived from the constant-acceleration equations, is applicable. We can use the equation giving the range of a projectile for equal initial and final elevations to evaluate the ranges of launches that exceed or fall short of 45° by the same amount.

Express the range of the projectile as a function of its initial speed and angle of launch:

$$R = \frac{v_0^2}{g}\sin 2\theta_0$$

Letting $\theta_0 = 45° \pm \theta$ yields:

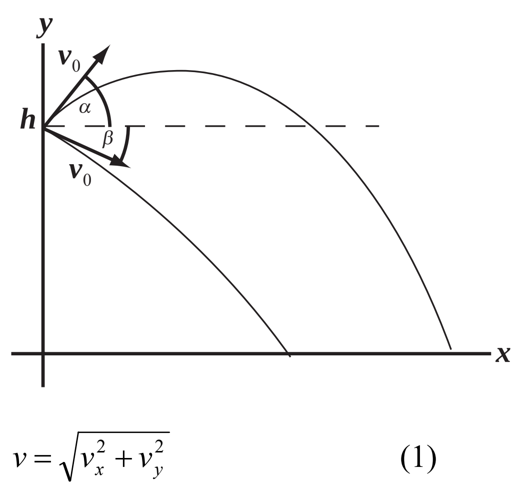
$$R = \frac{v_0^2}{g}\sin(90° \pm 2\theta) = \frac{v_0^2}{g}\cos(\pm 2\theta)$$

Because cos(–*θ*) = cos(+*θ*) (the cosine function is an *even* function):

$$\boxed{R(45° + \theta) = R(45° - \theta)}$$

118 •• Two balls are thrown with equal speeds from the top of a cliff of height *h*. One ball is thrown at an angle of α above the horizontal. The other ball is thrown at an angle of β below the horizontal. Show that each ball strikes the ground with the same speed, and find that speed in terms of *h* and the initial speed v_0. Neglect any effects due to air resistance.

Picture the Problem In the absence of air resistance, the acceleration of both balls is that due to gravity and the horizontal and vertical motions are independent of each other. Choose a coordinate system with the origin at the base of the cliff and the coordinate axes oriented as shown and use constant-acceleration equations to relate the *x* and *y* components of the ball's speed.



The speed of each ball on impact is:

$$v = \sqrt{v_x^2 + v_y^2} \qquad (1)$$

Independently of whether a ball is thrown upward at the angle α or downward at β, the vertical motion is described by:

$$v_y^2 = v_{0y}^2 + 2a_y\Delta y$$
$$= v_{0y}^2 - 2gh$$

The horizontal component of the speed of each ball is:

$$v_x = v_{0x}$$

Substitute for v_x and v_y in equation (1) and simplify to obtain:

$$v = \sqrt{v_{0x}^2 + v_{0y}^2 - 2gh} = \boxed{\sqrt{v_0^2 - 2gh}}$$

119 •• In his car, a driver tosses an egg vertically from chest height so that the peak of its path is just below the ceiling of the passenger compartment, which is 65 cm above his release point. He catches the egg at the same height at which he released it. If you are a roadside observer, and measure the horizontal distance between catch and release points to be 19 m, (*a*) how fast is the car moving? (*b*) In your reference frame, at what angle above the horizontal was the egg thrown?

Picture the Problem For the first part of the question, we simply need to determine the time interval for the ball's "flight." In order to determine that, we need only consider the time required for an egg to fall 65 cm under the influence of gravity and then double that time. The path taken by the egg, according to the one observing on the side of the road, is a parabola – in fact, its path is indistinguishable from that of a projectile. We can obtain the apparent angle of launch by noting that the horizontal component of the egg's motion is simply given by the speed of the car, while the vertical component is given by the speed of the toss necessary to reach a height of 0.65 m.

(*a*) The speed of the car is given by:

$$v_{\text{car}} = \frac{\Delta x}{\Delta t_{\text{flight}}} \qquad (1)$$

where Δx is the distance the car moves during the time Δt_{flight} the egg is in flight.

The fall time, Δt_{fall}, for the egg to fall (from rest) and the distance Δh it falls are related according to:

$$\Delta h = \tfrac{1}{2}g(\Delta t_{\text{fall}})^2 \Rightarrow \Delta t_{\text{fall}} = \sqrt{\frac{2\Delta h}{\text{g}}}$$

The time-of-flight is twice the egg's fall time:

$$\Delta t_{\text{flight}} = 2\Delta t_{\text{fall}}$$

Substitute for Δt_{fall} to obtain:

$$\Delta t_{\text{flight}} = 2\sqrt{\frac{2\Delta h}{\text{g}}}$$

Substituting for Δt_{flight} in equation (1) yields:

$$v_{\text{car}} = \frac{\Delta x}{2\sqrt{\frac{2\Delta h}{g}}} = \frac{\Delta x}{2}\sqrt{\frac{g}{2\Delta h}} \quad (2)$$

Substitute numerical values and evaluate v_{car}:

$$v_{\text{car}} = \frac{19\text{ m}}{2}\sqrt{\frac{9.81\text{ m/s}^2}{2(0.65\text{ m})}} = \boxed{26\text{ m/s}}$$

(*b*) The angle θ_0 at which the egg was thrown is given by:

$$\theta_0 = \tan^{-1}\left(\frac{v_{0y}}{v_{0x}}\right) \quad (3)$$

Use a constant-acceleration equation to relate the final upward speed of the egg to its initial speed and its maximum height Δh:

$$v_y^2 = v_{0y}^2 + 2a_y\Delta h$$

or, because $v_y = 0$ and $a_y = -g$,

$$0 = v_{0y}^2 - 2g\Delta h$$

Solve for v_{0y} to obtain:

$$v_{0y} = \sqrt{2g\Delta h}$$

v_{0x} is the speed of the car. Substituting in equation (2) yields:

$$v_{\text{car}} = v_{0x} = \frac{\Delta x}{2}\sqrt{\frac{g}{2\Delta h}}$$

Substitute for v_{0x} in equation (3) to obtain:

$$\theta_0 = \tan^{-1}\left(\frac{v_{0y}}{\frac{\Delta x}{2}\sqrt{\frac{g}{2\Delta h}}}\right) = \tan^{-1}\left(\frac{4\Delta h}{\Delta x}\right)$$

Substitute numerical values and evaluate θ_0:

$$\theta_0 = \tan^{-1}\left(\frac{4(0.65\text{ m})}{19\text{ m}}\right) = \boxed{7.8°}$$

120 ••• A straight line is drawn on the surface of a 16-cm-radius turntable from the center to the perimeter. A bug crawls along this line from the center outward as the turntable spins counterclockwise at a constant 45 rpm. Its walking speed relative to the turntable is a steady 3.5 cm/s. Let its initial heading be in the positive *x*-direction. As the bug reaches the edge of the turntable, and falls off, (still traveling at 3.5 cm/s radially, relative to the turntable, what are the *x* and *y* components of the velocity of the bug?

Picture the Problem In order to determine the total velocity vector of the bug we need to consider the two components that must be added together, namely, the bug's velocity relative to the turntable at its point of departure from the turntable, and the velocity of the point on the turntable from which the bug steps off relative to the ground.

Express the velocity of the bug relative to the ground $\vec{v}_{\text{Bg}}$:

$$\vec{v}_{\text{Bg}} = \vec{v}_{\text{BT}} + \vec{v}_{\text{Tg}} \qquad (1)$$

where $\vec{v}_{\text{BT}}$ is the velocity of the bug relative to the turntable and $\vec{v}_{\text{Tg}}$ is the velocity of the turntable relative to the ground.

The angle through which the turntable has rotated when the bug reaches its edge is given by:

$$\Delta\theta = \left(\frac{360°}{1\text{ rev}}\right)\Delta t = \left(\frac{360°}{1\text{ rev}}\right)\left(\frac{R}{v}\right)$$

where R is the radius of the turntable and v is the speed of the bug.

Substitute numerical values and evaluate $\Delta\theta$:

$$\Delta\theta = \left(\frac{360°}{1\text{ rev}} \times \frac{45\text{ rev}}{\text{min}} \times \frac{1\text{ min}}{60\text{ s}}\right)\left(\frac{16\text{ cm}}{3.5\text{ cm/s}}\right) = 1234°$$

The number of degrees beyond an integer multiple of revolutions is:

$$\theta = \Delta\theta - 360°n = 1234° - 360°(3)$$
$$= 154°$$

Now we can express the velocity of the bug relative to the turntable:

$$\vec{v}_{\text{BT}} = (v_{\text{B}}\cos\theta)\hat{\boldsymbol{i}} + (v_{\text{B}}\sin\theta)\hat{\boldsymbol{j}}$$

Substitute numerical values and evaluate $\vec{v}_{\text{BT}}$:

$$\begin{aligned}\vec{v}_{\text{BT}} &= ((3.5\text{ cm/s})\cos 154°)\hat{\boldsymbol{i}} + ((3.5\text{ cm/s})\sin 154°)\hat{\boldsymbol{j}} \\ &= (-3.146\text{ cm/s})\hat{\boldsymbol{i}} + (1.534\text{ cm/s})\hat{\boldsymbol{j}}\end{aligned}$$

The point on the turntable from which the bug leaves the turntable is moving with a velocity vector pointed 90° ahead of $\vec{v}_{\text{BT}}$; that is, tangent to the turntable:

$$\vec{v}_{\text{Tg}} = v_{\text{turntable}}\cos(\theta + 90°)\hat{\boldsymbol{i}} + v_{\text{turntable}}\sin(\theta + 90°)\hat{\boldsymbol{j}}$$

The velocity of the turntable is given by:

$$v_{\text{turntable}} = \frac{2\pi R}{T}$$

where T is the period of the turntable's motion.

Substitute numerical values and evaluate $v_{\text{turntable}}$:

$$v_{\text{turntable}} = \frac{2\pi(16\text{ cm/s})}{\dfrac{60\text{ s}}{45\text{ rev}}} = 75.40\text{ cm/s}$$

Substitute in the expression for $\vec{v}_{\text{Tg}}$ and simplify to obtain:

$$\begin{aligned}\vec{v}_{\text{Tg}} &= (75.40\text{ cm/s})\cos(154° + 90°)\hat{i} + (75.40\text{ cm/s})\sin(154° + 90°)\hat{j} \\ &= (-33.05\text{ cm/s})\hat{i} + (-67.77\text{ cm/s})\hat{j}\end{aligned}$$

Finally, substitute for $\vec{v}_{\text{BT}}$ and $\vec{v}_{\text{Tg}}$ in equation (1) and simplify:

$$\begin{aligned}\vec{v}_{\text{Bg}} &= (-3.146\text{ cm/s})\hat{i} + (1.534\text{ cm/s})\hat{j} + (-33.05\text{ cm/s})\hat{i} + (-67.77\text{ cm/s})\hat{j} \\ &= (-36\text{ cm/s})\hat{i} + (-66\text{ cm/s})\hat{j}\end{aligned}$$

The x and y components of the velocity of the bug are:

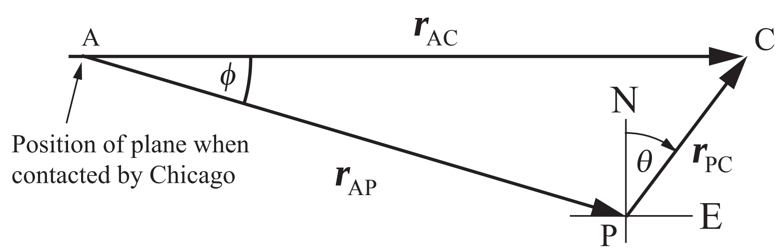
$$v_{x,\text{Bug}} = \boxed{-36\text{ cm/s}}$$

and

$$v_{y,\text{Bug}} = \boxed{-66\text{ cm/s}}$$

121 ••• On a windless day, a stunt pilot is flying his vintage World War I Sopwith Camel from Dubuque, Iowa, to Chicago, Illinois for an air show. Unfortunately, he is unaware that his plane's ancient magnetic compass has a serious problem in that what it records as "north" is in fact 16.5° east of true north. At one moment during his flight, the airport in Chicago notifies him that he is, in reality, 150 km due west of the airport. He then turns due east, according to his plane's compass, and flies for 45 minutes at 150 km/hr. At that point, he expected to see the airport and begin final descent. What is the plane's actual distance from Chicago and what should be his heading if he is to fly directly to Chicago?

Picture the Problem The error in the guidance computer aboard the airplane implies that when the pilot flies the plane at what he thinks is a heading of due east, he is in fact flying at a heading of 16.5° south of east. When he has flown at 150 km/hr for 15 minutes along that heading he is therefore somewhat west and south of Chicago. In the following diagram, A identifies the position of the plane when contacted by the airport in Chicago, C the location of Chicago, and P the location of the plane after it has flown for 45 minutes at 150 km/h. Choose a coordinate system in which the $+x$ direction is to the east and the $+y$ direction is to the north. Expressing the vector $\vec{r}_{\text{CP}}$ in unit vector notation will allow us to find the plane's actual distance from Chicago (the magnitude of $\vec{r}_{\text{CP}}$) and the heading of Chicago (the direction of $-\vec{r}_{\text{CP}}$.



The plane's true distance from Chicago is given by the magnitude of vector $\vec{r}_{PC}$:

$$r_{PC} = \sqrt{r_{PC,x}^2 + r_{PC,y}^2} \quad (1)$$

The actual heading of Chicago relative to the plane's current position is given by:

$$\theta = \tan^{-1}\left(\frac{r_{PC,x}}{r_{PC,y}}\right) \quad (2)$$

Express the relationship between the vectors $\vec{r}_{AC}$, $\vec{r}_{PC}$, and $\vec{r}_{AP}$:

$$\vec{r}_{AP} + \vec{r}_{PC} = \vec{r}_{AC}$$
or
$$\vec{r}_{PC} = \vec{r}_{AC} - \vec{r}_{AP} \quad (3)$$

The vector $\vec{r}_{AP}$ is given by:

$$\vec{r}_{AP} = r_{AP}\cos\phi\,\hat{\boldsymbol{i}} - r_{AP}\sin\phi\,\hat{\boldsymbol{j}}$$

Substitute numerical values and simplify to obtain:

$$\begin{aligned}\vec{r}_{AP} &= \left[\left(150\,\frac{\text{km}}{\text{h}}\times 0.75\,\text{h}\right)\cos 16.5°\right]\hat{\boldsymbol{i}} - \left[\left(150\,\frac{\text{km}}{\text{h}}\times 0.75\,\text{h}\right)\sin 16.5°\right]\hat{\boldsymbol{j}}\\ &= (107.9\,\text{km})\hat{\boldsymbol{i}} - (31.95\,\text{km})\hat{\boldsymbol{j}}\end{aligned}$$

The vector $\vec{r}_{AC}$ is given by:

$$\vec{r}_{AC} = (150\,\text{km})\hat{\boldsymbol{i}}$$

Substitute for $\vec{r}_{AP}$ and $\vec{r}_{AC}$ in equation (3) to obtain:

$$\begin{aligned}\vec{r}_{PC} &= (150\,\text{km})\hat{\boldsymbol{i}} - \left[(107.9\,\text{km})\hat{\boldsymbol{i}} - (31.95\,\text{km})\hat{\boldsymbol{j}}\right]\\ &= (42.10\,\text{km})\hat{\boldsymbol{i}} + (31.95\,\text{km})\hat{\boldsymbol{j}}\end{aligned}$$

Substituting numerical values in equation (1) and evaluate r_{PC}:

$$r_{PC} = \sqrt{(42.10\,\text{km})^2 + (31.95\,\text{km})^2} = \boxed{52.9\,\text{km}}$$

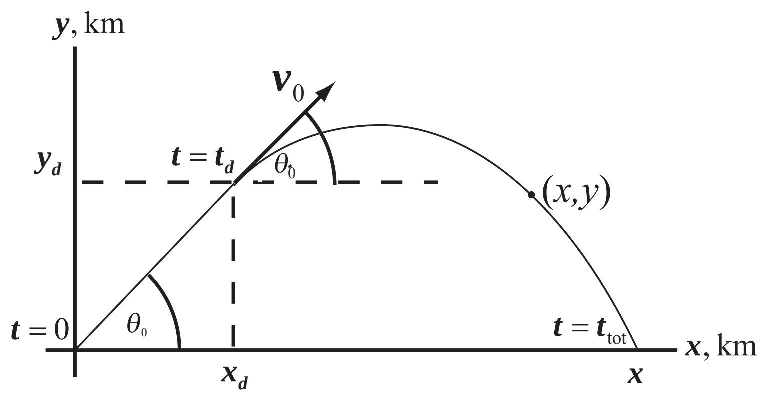
Substituting numerical values in equation (2) and evaluate θ:

$$\theta = \tan^{-1}\left(\frac{42.10\text{ km}}{31.95\text{ km}}\right) = 52.8°$$

$$= \boxed{52.8° \text{ east of north}}$$

122 ••• A cargo plane in flight lost a package because somebody forgot to close the rear cargo doors. You are on the team of safety experts trying to analyze what happened. From the point of takeoff, while climbing to altitude, the airplane traveled in a straight line at a constant speed of 275 mi/h at an angle of 37° above the horizontal. During this ascent, the package slid off the back ramp. You found the package in a field a distance of 7.5 km from the takeoff point. To complete the investigation you need to know exactly how long after takeoff the package slid off the back ramp of the plane. (Consider the sliding speed to be negligible.) Calculate the time at which the package fell off the back ramp. Ignore any effects due to air resistance.

Picture the Problem We can solve this problem by first considering what the projectile is doing while it is still in the cargo plane and then considering its motion as a projectile. The following diagram shows a convenient choice of coordinate system and the trajectory of the package both in the plane and when it has become a projectile. We can use constant-acceleration equations to describe both parts of its motion.



Express the x- and y-coordinates of the drop point:

$$x_d = v_{x,d}t_d \quad (1)$$

and

$$y_d = v_{y,d}t_d \quad (2)$$

Express the x- and y-coordinates of the package along its parabolic trajectory (after it has fallen out of the plane):

$$x(t) = x_d + v_{x,d}(t - t_d)$$

and

$$y(t) = y_d + v_{y,d}(t - t_d) - \tfrac{1}{2}g(t - t_d)^2$$

Substitute for x_d and y_d from equations (1) and (2) and simplify to obtain:

$$x(t) = v_{x,d}t_d + v_{x,d}(t - t_d) = v_{x,d}t$$

and

$$y(t) = v_{y,d}t_d + v_{y,d}(t - t_d) - \tfrac{1}{2}g(t - t_d)^2$$
$$= v_{y,d}t - \tfrac{1}{2}g(t - t_d)^2$$

Express the x and y components of the plane's (and package's) velocity at the drop point:

$$v_{x,d} = v_{\text{plane}}\cos\theta_0$$

and

$$v_{y,d} = v_{\text{plane}}\sin\theta_0$$

$$v_{x,d} = \left(275\,\frac{\text{mi}}{\text{h}} \times 1609\,\frac{\text{m}}{\text{mi}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)\cos 37° = 98.16\ \text{m/s}$$

and

$$v_{y,d} = \left(275\,\frac{\text{mi}}{\text{h}} \times 1609\,\frac{\text{m}}{\text{mi}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)\sin 37° = 73.97\ \text{m/s}$$

At impact ($t = t_{\text{tot}}$):

$$x(t_{\text{tot}}) = x_\ell \text{ and } y(t_{\text{tot}}) = 0$$

The distance-to-impact is also given by:

$$x_\ell = v_{x,d}t_{\text{tot}} \Rightarrow t_{\text{tot}} = \frac{x_\ell}{v_{x,d}}$$

Substitute for t_{tot} in the $y(t)$ equation to obtain:

$$0 = v_{y,d}t_{\text{tot}} - \tfrac{1}{2}g(t_{\text{tot}} - t_d)^2$$

or, because $t_{\text{tot}} = x_\ell / v_{x,d}$,

$$0 = v_{y,d}\frac{x_\ell}{v_{x,d}} - \tfrac{1}{2}g\left(\frac{x_\ell}{v_{x,d}} - t_d\right)^2$$

Expand the binomial term and simplify the resulting expression to obtain the quadratic equation:

$$t_d^2 - \frac{2x_\ell}{v_{x,d}}t_d + \left[\frac{x_\ell^2}{v_{x,d}^2} - \frac{2x_\ell v_{y,d}}{g v_{x,d}}\right] = 0$$

Substitute numerical values to obtain:

$$t_d^2 - \frac{2(7.5\ \text{km})}{98.16\ \text{m/s}}t_d + \left[\frac{(7.5\ \text{km})^2}{(98.16\ \text{m/s})^2} - \frac{2(7.5\ \text{km})(73.97\ \text{m/s})}{(9.81\ \text{m/s}^2)(98.16\ \text{m/s})}\right] = 0$$

Simplification of this expression yields:

$$t_d^2 - (152.8\ \text{s})t_d + 4686\ \text{s}^2 = 0$$

Use the quadratic formula or your graphing calculator to obtain:

$t_d = 110\text{ s or }42\text{ s}$

Because 110 s gives too long a distance for the range of the package,

$t_d = \boxed{42\text{ s}}$

Chapter 4
Newton's Laws

Conceptual Problems

1 • While on a very smooth level transcontinental plane flight, your coffee cup sits motionless on your tray. Are there forces acting on the cup? If so, how do they differ from the forces that would be acting on the cup if it sat on your kitchen table at home?

Determine the Concept Yes, there are forces acting on it. They are the normal force of the table and the gravitational pull of Earth (weight). Because the cup is not accelerating relative to the ground, the forces are the same as those that would act on it if it was sitting on your table at home.

2 • You are passing another car on a highway and determine that, relative to you, the car you pass has an acceleration $\vec{a}$ to the west. However, the driver of the other car is maintaining a constant speed and direction relative to the road. Is the reference frame of your car an inertial one? If not, in which direction (east or west) is your car accelerating relative to the other car?

Determine the Concept No. You are in a non-inertial frame that is accelerating to the east, opposite the other car's apparent acceleration.

3 • [**SSM**] You are riding in a limousine that has opaque windows that do not allow you to see outside. The car is on a flat horizontal plane, so the car can accelerate by speeding up, slowing down, or turning. Equipped with just a small heavy object on the end of a string, how can you use it to determine if the limousine is changing either speed or direction? Can you determine the limousine's velocity?

Determine the Concept In the limo you hold one end of the string and suspend the object from the other end. If the string remains vertical, the reference frame of the limo is an inertial reference frame.

4 •• If only a single nonzero force acts on an object, does the object accelerate relative to all inertial reference frames? Is it possible for such an object to have zero velocity in some inertial reference frame and not in another? If so, give a specific example.

Determine the Concept An object accelerates when a *net* force acts on it. The fact that an object is accelerating tells us nothing about its velocity other than that it is always changing.

Yes, the object must have acceleration relative to all inertial frames of reference. According to Newton's first and second laws, an object must accelerate, relative to any inertial reference frame, in the direction of the net force. If there is ″only a single nonzero force,″ then this force is the net force.

Yes, the object's velocity may be momentarily zero in some inertial reference frame and not in another. During the period in which the force is acting, the object may be momentarily at rest, but its velocity cannot remain zero because it must continue to accelerate. Thus, its velocity is always changing.

5 •• A baseball is acted upon by a single known force. From this information alone, can you tell in which direction the baseball is moving relative to some reference frame? Explain.

Determine the Concept No. Predicting the direction of the subsequent motion correctly requires additional information (knowledge of the initial velocity as well as the acceleration). While the acceleration can be obtained from the net force through Newton's second law, the velocity can only be obtained by integrating the acceleration.

6 •• A truck moves directly away from you at constant velocity (as observed by you while standing in the middle of the road). It follows that (*a*) no forces act on the truck, (*b*) a constant force acts on the truck in the direction of its velocity, (*c*) the net force acting on the truck is zero, (*d*) the net force acting on the truck is its weight.

Determine the Concept An object in an inertial reference frame accelerates if there is a *net* force acting on it. Because the object is moving at constant velocity, the net force acting on it is zero. $\boxed{(c)}$ is correct.

7 •• Several space probes have been launched that are now far out in space *Pioneer 10*, for example, was launched in the 1970s and is still moving away from the Sun and its planets. Is the mass of *Pioneer 10* changing? Which of the known fundamental forces continue to act on it? Does it have a net force on it?

Determine the Concept No. The mass of the probe is constant. However, the solar system will attract the probe with a gravitational force. As the distance between *Pioneer 10* and the solar system becomes larger, the magnitude of the gravitational force becomes smaller. There is a net force on the probe because no other forces act on it.

8 •• Astronauts in apparent weightlessness during their stay on the International Space Station must carefully monitor their masses because significant loss of body mass is known to cause serious medical problems. Give an example of how you might design equipment to measure the mass of an astronaut on the orbiting space station.

Determine the Concept You could use a calibrated spring (a spring with a known stiffness constant) to pull on each astronaut and measure their resulting acceleration. Then you could use Newton's second law to calculate their mass.

9 •• [SSM] You are riding in an elevator. Describe two situations in which your apparent weight is greater than your true weight.

Determine the Concept Your apparent weight is the reading of a scale. If the acceleration of the elevator (and you) is directed upward, the normal force exerted by the scale on you is greater than your weight. You could be moving down but slowing or moving up and speeding up. In both cases your acceleration is upward.

10 •• Suppose you are in a train moving at constant velocity relative to the ground. You toss a ball to your friend several seats in front of you. Use Newton's second law to explain why you cannot use your observations of the tossed ball to determine the train's velocity relative to the ground.

Determine the Concept Because you are moving with constant velocity, your frame of reference is an inertial reference frame. In an inertial reference frame there are no fictitious forces. Thus moving or not moving, the ball will follow the same trajectory in your reference frame. The net force on the ball is the same, so its acceleration is the same.

11 •• Explain why, of the fundamental interactions, the gravitational interaction is the main concern in our everyday lives. One other on this list also plays an increasingly significant role in our rapidly advancing technology. Which one is that? Why are the others not obviously important?

Determine the Concept The most significant force in our everyday world is gravity. It literally keeps us on or near the ground. The other most common force is the electromagnetic force. It provides the ″glue″ to hold solids together and make them rigid. It is of great importance in electric circuits.

12 •• Give an example of an object that has three forces acting on it, and (*a*) accelerates, (*b*) moves at constant (non-zero) velocity, and (*c*) remains at rest.

(*a*) Any object for which the vector sum of the three forces doesn't add to zero. For example, a sled on a frictionless surface pulled horizontally. The normal force plus the weight plus the pulling force do not add to zero, so the sled accelerates.

(*b*) Pulling a fish vertically upward at constant velocity while it is still in the water. The forces acting on the fish are the pull, the gravitational force (weight of the fish), and water drag forces. These forces add up to zero.

(*c*) The three forces need to add vectorially to zero. An example is a picture hung by two wires.

13 •• [SSM] Suppose a block of mass m_1 rests on a block of mass m_2 and the combination rests on a table as shown in Figure 4-33. Tell the name of the force and its category (contact versus action-at-a-distance) for each of the following forces; (*a*) force exerted by m_1 on m_2, (*b*) force exerted by m_2 on m_1, (*c*) force exerted by m_2 on the table, (*d*) force exerted by the table on m_2, (*e*) force exerted by Earth on m_2. Which, if any, of these forces constitute a Newton's third law pair of forces?

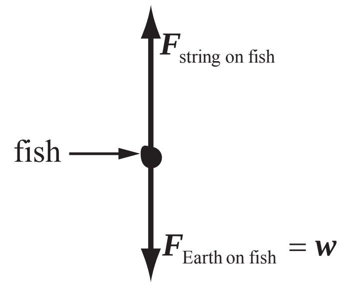
Determine the Concept

(*a*) The force exerted by m_1 on m_2.	Normal force, contact
(*b*) The force exerted by m_2 on m_1.	Normal force, contact
(*c*) The force exerted by m_2 on the table.	Normal force, contact
(*d*) The force exerted by the table on m_2.	Normal force, contact
(*e*) The force exerted by Earth on m_2.	Gravitational force, action-at-a-distance

The Newton's third law force pairs are the two normal forces between the two blocks and the two normal forces between the table and the bottom block. The gravitational force has a third law force pair that acts on Earth and so is not in the question set.

14 •• You yank a fish you have just caught on your line upward from rest into your boat. Draw a free-body diagram of the fish after it has left the water and as it gains speed as it rises. In addition, tell the type (tension, spring, gravity, normal, friction, etc.) and category (contact versus action-at-a-distance) for each force on your diagram. Which, if any, pairs of the forces on your diagram constitute a Newton's third law pair? Can you tell the relative magnitudes of the forces from the information given? Explain.

Determine the Concept A free-body diagram showing the forces acting on the fish is shown to the right. The forces do not constitute a Newton's 3rd law pair. A table summarizing the type and category of the forces is shown below.



Force	Type	Category
$\vec{F}_{\text{string on fish}}$	Tension	Contact
$\vec{F}_{\text{Earth on fish}}$	Gravity	Action-at-a-distance

Because the fish accelerates upward, the tension force must be greater in magnitude than the gravitational force acting on the fish.

15 • If you gently set a fancy plate on the table, it will not break. However if you drop it from a height, it might very well break. Discuss the forces that act on the plate (as it contacts the table) in both these situations. Use kinematics and Newton's second law to describe what is different about the second situation that causes the plate to break.

Determine the Concept When the plate is sitting on the table, the normal force F_{n} acting upward on it is exerted by the table and is the same size as the gravitational force F_g acting on the plate. Hence, the plate does not accelerate. However, to slow the plate down as it hits the table requires that $F_{\text{n}} > F_g$ (or $F_{\text{n}} >> F_g$ if the table is hard and the plate slows quickly). A large normal force exerted on delicate china can easily break it.

16 •• For each of the following forces, give what produces it, what object it acts on, its direction, and the reaction force. (*a*) The force you exert on your briefcase as you hold it while standing at the bus stop. (*b*) The normal force on the soles of your feet as you stand barefooted on a horizontal wood floor. (*c*) The gravitational force on you as you stand on a horizontal floor. (*d*) The horizontal force exerted on a baseball by a bat as the ball is hit straight up the middle towards center field for a single.

Determine the Concept

(*a*) The force you exert on your briefcase to hold it while standing at the bus stop:

You produce this force. It acts on the briefcase. It acts upward. The reaction force is the force the briefcase exerts on your hand.

(*b*) The normal force on the soles of your feet as you stand barefooted on a horizontal wood floor.	The floor produces this force. It acts on your feet. It acts upward. The reaction force is the force your feet exert on the floor.
(*c*) The gravitational force on you as you stand on a horizontal floor.	Earth produces this force. It acts on you. It acts downward. The reaction force is the gravitational force you exert on Earth.
(*d*) The horizontal force exerted on a baseball by a bat as the ball is hit straight up the middle towards center field for a single.	The bat produces this force. It acts on the ball. It acts horizontally. The reaction force is the force the ball exerts on the bat.

17 •• For each case, identify the force (including its direction) that causes the acceleration. (*a*) A sprinter at the very start of the race. (*b*) A hockey puck skidding freely but slowly coming to rest on the ice. (*c*) A long fly ball at the top of its arc. (*d*) A bungee jumper at the very bottom of her descent.

Determine the Concept

(*a*) A sprinter at the very start of the race:	The normal force of the block on the sprinter, in the forward direction.
(*b*) A hockey puck skidding freely but slowly coming to rest on the ice:	The frictional force by the ice on the puck, in the opposite direction to the velocity.
(*c*) A long fly ball at the top of its arc:	The gravitation force by Earth on the ball, in the downward direction.
(*d*) A bungee jumper at the very bottom of her descent:	The force exerted by the bungee cord on the jumper, in the upward direction.

18 • True or false:

(*a*) If two external forces that are both equal in magnitude and opposite in direction act on the same object, the two forces can never be a Newton's third law pair.
(*b*) The two forces of a Newton's third law pair are equal only if the objects involved are not accelerating.

(*a*) True. By definition, third law pairs cannot act on the same object.

(*b*) False. Action and reaction forces are equal independently of any motion of the involved objects.

19 •• An 80-kg man on ice skates is pushing his 40-kg son, also on skates, with a force of 100 N. Together, they move across the ice steadily gaining speed. (*a*) The force exerted by the boy on his father is (1) 200 N, (2) 100 N, (3) 50 N, or (4) 40 N. (*b*) How do the magnitudes of the two accelerations compare? (*c*) How do the directions of the two accelerations compare?

Determine the Concept

(*a*) (2) These forces are a Newton 3^{rd} law force pair, and so the force exerted by the boy on his father is 100 N.

(*b*) Because the father and son move together, their accelerations will be the same.

(*c*) The directions of their acceleration are the same.

20 •• A girl holds a stone in her hand and can move it up or down or keep it still. True or false: (*a*) The force exerted by her hand on the rock is always the same magnitude as the weight of the stone. (*b*) The force exerted by her hand on the rock is the reaction force to the pull of gravity on the stone. (*c*) The force exerted by her hand is always the same size the force her hand feels from the stone but in the opposite direction. (*d*) If the girl moves her hand down at a constant speed, then her upward force on the stone is less than the weight of the stone. (*e*) If the girl moves her hand downward but slows the stone to rest, the force of the stone on the girl's hand is the same magnitude as the pull of gravity on the stone.

(*a*) False. If the rock is accelerating, the force the girl exerts must be greater than the weight of the stone.

(*b*) False. The reaction force to the pull of gravity is the force the rock exerts on Earth.

(*c*) True. These forces constitute a Newton's third law pair.

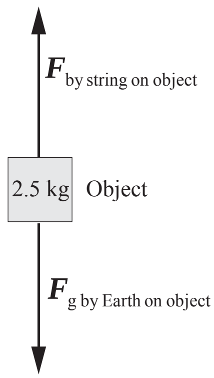
(*d*) False. If she moves the stone downward at a constant speed, the net force acting on the stone must be zero.

(*e*) False. If she is slowing the stone, it is experiencing acceleration and the net force acting on it can not be zero. The force of her hand on the stone, which has the same magnitude as the force of the stone on her hand, is greater than the force of gravity on the stone.

21 •• **[SSM]** A 2.5-kg object hangs at rest from a string attached to the ceiling. (*a*) Draw a free body diagram of the object, indicate the reaction force to each force drawn, and tell what object the reaction force acts on. (*b*) Draw a free body diagram of the string, indicate the reaction force to each force drawn, and tell what object each reaction force acts on. Do not neglect the mass of the string.

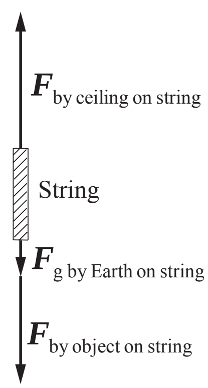
Determine the Concept The force diagrams will need to include forces exerted by the ceiling, on the string, on the object, and forces exerted by Earth.

(*a*)



Force	Third-Law Pair
$\vec{F}_{\text{by string on object}}$	$\vec{F}_{\text{by object on string}}$
$\vec{F}_{\text{g by Earth on object}}$	$\vec{F}_{\text{by object on Earth}}$

(*b*)



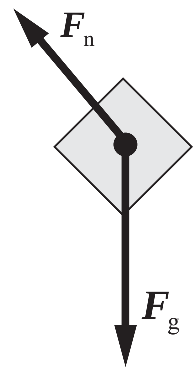
Force	Third-Law Pair
$\vec{F}_{\text{by ceiling on string}}$	$\vec{F}_{\text{by string on ceiling}}$
$\vec{F}_{\text{by Earth on string}}$	$\vec{F}_{\text{by string on Earth}}$
$\vec{F}_{\text{by object on string}}$	$\vec{F}_{\text{by string on object}}$

22 •• (*a*) Which of the free-body diagrams in Figure 4-34. represents a block sliding down a frictionless inclined surface? (*b*) For the correct figure, label the forces and tell which are contact forces and which are action-at-a-distance forces. (*c*) For each force in the correct figure, identify the reaction force, the object it acts on and its direction.

Determine the Concept Identify the objects in the block's environment that are exerting forces on the block and then decide in what directions those forces must be acting if the block is sliding *down* the inclined plane.

(*a*) Free-body diagram $\boxed{(c)}$ is correct.

(*b*) Because the incline is frictionless, the force $\vec{F}_n$ the incline exerts on the block must be normal to the surface and is a contact force. The second object capable of exerting a force on the block is Earth and its force; the gravitational force $\vec{F}_g$ acting on the block acts directly downward and is an action-at-a-distance force. The magnitude of the normal force is less than that of the weight because it supports only a portion of the weight.

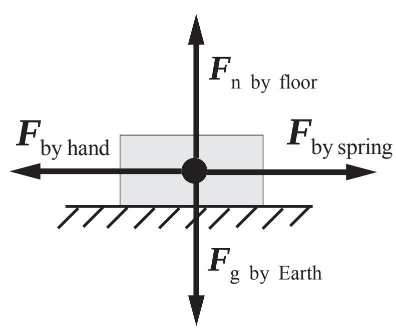


(*c*) The reaction to the normal force is the force the block exerts perpendicularly on the surface of the incline. The reaction to the gravitational force is the upward force the block exerts on Earth.

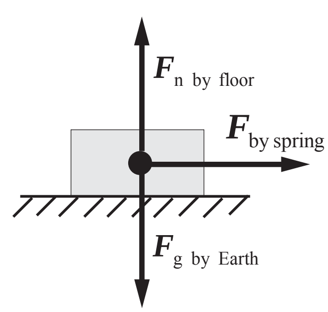
23 •• A wooden box on the floor is pressed against a compressed, horizontal spring that is attached to a wall. The horizontal floor beneath the box is frictionless. Draw the free body diagram of the box in the following cases. (*a*) The box is held at rest against the compressed spring. (*b*) The force holding the box against the spring no longer exists, but the box is still in contact with the spring. (*c*) When the box no longer has contact with the spring.

Determine the Concept In the following free-body diagrams we'll assume that the box is initially pushed to the left to compress the spring.

(*a*) Note that, in the free-body diagram to the right, that $\left|\vec{F}_{\text{n by floor}}\right| = \left|\vec{F}_{\text{g by Earth}}\right|$ and $\left|\vec{F}_{\text{by spring}}\right| = \left|\vec{F}_{\text{by hand}}\right|$.

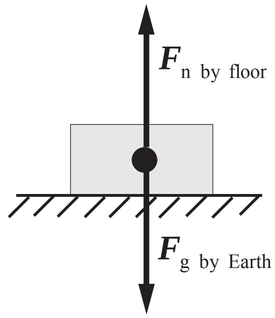


(*b*) Note that while $\vec{F}_{\text{n by floor}} = \left|\vec{F}_{\text{g by Earth}}\right|$, $\vec{F}_{\text{by spring}}$ is now the net force acting on the box. As the spring decompresses, $\vec{F}_{\text{by spring}}$ will become smaller.



(*c*) When the box separates from the spring, the force exerted by the spring on the box goes to zero. Note that it is still true that

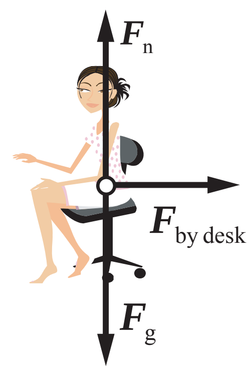
$\vec{F}_{\text{n by floor}} = \left|\vec{F}_{\text{g by Earth}}\right|$.



24 •• Imagine yourself seated on a wheeled desk chair at your desk. Consider any friction forces between the chair and the floor to be negligible. However, the friction forces between the desk and the floor are not negligible. When sitting at rest, you decide you need another cup of coffee. You push horizontally against the desk, and the chair rolls backward away from the desk. (*a*) Draw your free-body diagram of yourself during the push and clearly indicate which force was responsible for your acceleration. (*b*) What is the reaction force to the force that caused your acceleration? (*c*) Draw the free-body diagram of the desk and explain why it did not accelerate. Does this violate Newton's third law? Explain.

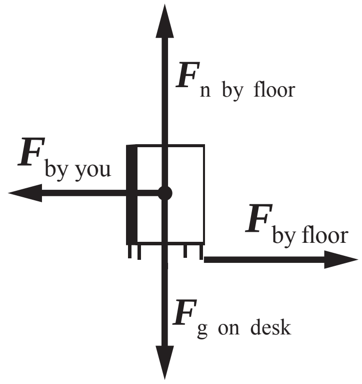
Determine the Concept In the following free-body diagrams we'll assume that the desk is to the left and that your motion is to the right.

(*a*) Newton's third law accounts for this as follows. When you push with your hands against the desk, the desk pushes back on your hands with a force of the same magnitude but opposite direction. This force accelerates you backward.



(*b*) The reaction force to the force that caused your acceleration is the force that you exerted on the desk.

(*c*) When you pushed on the desk, you did not apply sufficient force to overcome the force of friction between the desk and the floor. In terms of forces on the desk, you applied a force, and the floor applied a friction force that, when added as vectors, cancelled. The desk, therefore, did not accelerate and Newton's third law is not violated. The forces in the diagram do not constitute a Newton's third law pair of forces, even though they are equal in magnitude and opposite in direction.



25 ••• The same (net) horizontal force F is applied for a fixed time interval Δt to each of two objects, having masses m_1 and m_2, that sit on a flat, frictionless surface. (Let $m_1 > m_2$.) (*a*) Assuming the two objects are initially at rest, what is the ratio of their accelerations during the time interval in terms of F, m_1 and m_2? (*b*) What is the ratio of their speeds v_1 and v_2 at the end of the time interval? (*c*) How far apart are the two objects (and which is ahead) the end of the time interval?

Picture the Problem We can apply Newton's second law to find the ratios of the accelerations and speeds of the two objects and constant-acceleration equations to express the separation of the objects as a function of the elapsed time.

(*a*) Use Newton's second law to express the accelerations of the two objects:

$$a_1 = \frac{F}{m_1} \text{ and } a_2 = \frac{F}{m_2}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{a_1}{a_2} = \frac{\frac{F}{m_1}}{\frac{F}{m_2}} = \boxed{\frac{m_2}{m_1}}$$

(*b*) Because both objects started from rest, their speeds after time Δt has elapsed are:

$$v_1 = a_1\Delta t \text{ and } v_2 = a_2\Delta t$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{v_1}{v_2} = \frac{a_1\Delta t}{a_2\Delta t} = \frac{a_1}{a_2} = \boxed{\frac{m_2}{m_1}}$$

(*c*) The separation of the two objects at the end of the time interval is given by:

$$\Delta x = \Delta x_2 - \Delta x_1 \qquad (1)$$

Using a constant acceleration equation, express the distances traveled by the two objects when time Δt has elapsed:

$$\Delta x_1 = \tfrac{1}{2}a_1(\Delta t)^2$$
and
$$\Delta x_2 = \tfrac{1}{2}a_2(\Delta t)^2$$

Substitute for Δx_1 and Δx_2 in equation (1) and simplify to obtain:

$$\Delta x = \tfrac{1}{2}a_2(\Delta t)^2 - \tfrac{1}{2}a_1(\Delta t)^2 = \boxed{\tfrac{1}{2}F\left(\frac{1}{m_2} - \frac{1}{m_1}\right)(\Delta t)^2}$$

and, because $m_1 > m_2$, the object whose mass is m_2 is ahead.

Estimation and Approximation

26 •• Most cars have four springs attaching the body to the frame, one at each wheel position. Devise an experimental method of estimating the force constant of one of the springs using your known weight and the weights of several of your friends. Assume the four springs are identical. Use the method to estimate the force constant of your car's springs.

Picture the Problem Suppose you put in 800 lbs (or about 3600 N) of weight and the car sags several inches (or 6.00 cm). Then each spring supports about 900 N and we can use the definition of the force constant k to determine its value.

The force constant is the ratio of the compressing (or stretching) force to the compression (or stretch):

$$k = \frac{F_x}{\Delta x}$$

Substitute numerical values and evaluate k:

$$k = \frac{\tfrac{1}{4}(3600\ \text{N})}{6.00\ \text{cm}} \approx \boxed{150\ \text{N/cm}}$$

27 •• **[SSM]** Estimate the force exerted on the goalie's glove by the puck when he catches a hard slap shot for a save.

Picture the Problem Suppose the goalie's glove slows the puck from 60 m/s to zero as it recoils a distance of 10 cm. Further, assume that the puck's mass is 200 g. Because the force the puck exerts on the goalie's glove and the force the goalie's glove exerts on the puck are action-and-reaction forces, they are equal in magnitude. Hence, if we use a constant-acceleration equation to find the puck's acceleration and Newton's second law to find the force the glove exerts on the puck, we'll have the magnitude of the force exerted on the goalie's glove.

Apply Newton's second law to the puck as it is slowed by the goalie's glove to express the magnitude of the force the glove exerts on the puck:

$$F_{\text{glove on puck}} = \left| m_{\text{puck}} a_{\text{puck}} \right| \qquad (1)$$

Use a constant-acceleration equation to relate the initial and final speeds of the puck to its acceleration and stopping distance:

$$v^2 = v_0^2 + 2a_{\text{puck}} (\Delta x)_{\text{puck}}$$

Solving for a_{puck} yields:

$$a_{\text{puck}} = \frac{v^2 - v_0^2}{2(\Delta x)_{\text{puck}}}$$

Substitute for a_{puck} in equation (1) to obtain:

$$F_{\text{glove on puck}} = \left| \frac{m_{\text{puck}} (v^2 - v_0^2)}{2(\Delta x)_{\text{puck}}} \right|$$

Substitute numerical values and evaluate $F_{\text{glove on puck}}$:

$$F_{\text{glove on puck}} = \left| \frac{(0.200\ \text{kg})\left(0 - (60\ \text{m/s})^2\right)}{2(0.10\ \text{m})} \right| \approx \boxed{3.6\ \text{kN}}$$

Remarks: The force on the puck is about 1800 times its weight.

28 •• A baseball player slides into second base during a steal attempt. Assuming reasonable values for the length of the slide, the speed of the player at the beginning of the slide, and the speed of the player at the end of the slide, estimate the average force of friction acting on the player.

Picture the Problem Let's assume that the player's mass is 100 kg, that he gets going fairly quickly down the base path, and that his speed is 8.0 m/s when he begins his slide. Further, let's assume that he approaches the base at the end of the slide at 3.0 m/s. From these speeds, and the length of the slide, we can use Newton's second law and a constant-acceleration equation to find the force due to friction (which causes the slowing down).

Apply Newton's second law to the sliding runner:

$$\sum F_x = F_{\text{friction}} = ma \qquad (1)$$

Using a constant-acceleration equation, relate the runner's initial and final speeds to his acceleration and the length of his slide:

$$v_{\text{f}}^2 = v_{\text{i}}^2 + 2a\Delta x \Rightarrow a = \frac{v_{\text{f}}^2 - v_{\text{i}}^2}{2\Delta x}$$

Substituting for a in equation (1) yields:

$$F_{\text{friction}} = m\frac{v_{\text{f}}^2 - v_{\text{i}}^2}{2\Delta x}$$

Assuming the player slides 2.0 m, substitute numerical values and evaluate F_{friction} :

$$F_{\text{friction}} = (100\text{ kg})\frac{(3.0\text{ m/s})^2 - (8.0\text{ m/s})^2}{2(2.0\text{ m})}$$

$$\approx \boxed{-1.4\text{ kN}}$$

where the minus sign indicates that the force of friction opposes the runner's motion.

29 •• A race car skidding out of control manages to slow down to 90 km/h before crashing head-on into a brick wall. Fortunately, the driver is wearing a safety harness. Using reasonable values for the mass of the driver and the stopping distance, estimate the average force exerted on the driver by the safety harness, including its direction. Neglect any effects of frictional forces on the driver by the seat.

Picture the Problem Assume a crush distance of 1.0 m at 90 km/h (25 m/s) and a driver's mass of 55 kg. We can use a constant-acceleration equation (the definition of average acceleration) to find the acceleration of the driver and Newton's second law to find the force exerted on the driver by the seat belt.

Apply Newton's second law to the driver as she is brought to rest by her safety harness:

$$F_{\substack{\text{safety harness}\\ \text{on driver}}} = m_{\text{driver}} a_{\text{driver}} \qquad (1)$$

Use a constant-acceleration equation to relate the initial and final speeds of the driver to her acceleration and stopping distance:

$$v^2 = v_0^2 + 2a_{\text{driver}}(\Delta x)_{\text{driver}}$$

Solving for a_{driver} yields:

$$a_{\text{driver}} = \frac{v^2 - v_0^2}{2(\Delta x)_{\text{driver}}}$$

Substitute for a_{driver} in equation (1) to obtain:

$$F_{\substack{\text{safety harness}\\ \text{on driver}}} = m_{\text{driver}}\left(\frac{v^2 - v_0^2}{2(\Delta x)_{\text{driver}}}\right)$$

Substitute numerical values and evaluate $F_{\substack{\text{safety harness}\\ \text{on driver}}}$:

$$F_{\substack{\text{safety harness}\\ \text{on driver}}} = (55\text{ kg})\left(\frac{0 - (25\text{ m/s})^2}{2(1.0\text{ m})}\right)$$

$$\approx \boxed{-17\text{ kN}}$$

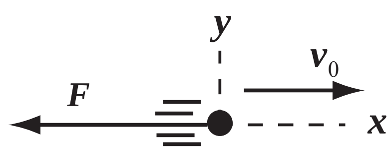
where the minus sign indicates that the force exerted by the safety harness is in the opposite direction from the driver's motion.

Remarks: The average force on the safety harness is about 32 times her weight.

Newton's First and Second Laws: Mass, Inertia, and Force

30 • A particle is traveling in a straight line at constant speed of 25.0 m/s. Suddenly a constant force of 15.0 N acts on it, bringing it to a stop in a distance of 62.5 m. (*a*) What is the direction of the force? (*b*) Determine the time it takes for the particle to come to a stop. (*c*) What is its mass?

Picture the Problem The acceleration of the particle, its stopping time, and its mass can be found using constant-acceleration equations and Newton's second law. A convenient coordinate system is shown in the following diagram.



(*a*) Because the constant force slows the particle, we can conclude that, as shown in the diagram, its direction is opposite the direction of the particle's motion.

(*b*) Use a constant-acceleration equation to relate the initial and final velocities of the particle to its acceleration and stopping time:

$$v_x = v_{0x} + a_x \Delta t$$

or, because $v_x = 0$,

$$0 = v_{0x} + a_x \Delta t \Rightarrow \Delta t = -\frac{v_{0x}}{a_x} \qquad (1)$$

Use a constant-acceleration equation to relate the initial and final velocities of the particle to its acceleration and stopping distance:

$$v_x^2 = v_{0x}^2 + 2a_x \Delta x$$

or, because $v_x = 0$,

$$0 = v_{0x}^2 + 2a_x \Delta x \Rightarrow a_x = \frac{-v_{0x}^2}{2\Delta x}$$

Substituting for a_x in equation (1) and simplifying yields:

$$\Delta t = \frac{2\Delta x}{v_{0x}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2(62.5\ \text{m})}{25.0\ \text{m/s}} = \boxed{5.00\ \text{s}}$$

(*c*) Apply Newton's second law to the particle to obtain:

$$\sum F_x = -F_{\text{net}} = ma_x$$

Solving for m yields:

$$m = \frac{-F_{\text{net}}}{a_x} \qquad (2)$$

Substitute for a_x in equation (2) to obtain:

$$m=\frac{2\Delta x F_{\text{net}}}{v_{0x}^2}$$

Substitute numerical values and evaluate m:

$$m=\frac{2(62.5\text{ m})(15.0\text{ N})}{(25.0\text{ m/s})^2}=\boxed{3.00\text{ kg}}$$

31 • An object has an acceleration of 3.0 m/s^2 when a single force of magnitude F_0 acts on it. (*a*) What is the magnitude of its acceleration when the magnitude of this force is doubled? (*b*) A second object has an acceleration of 9.0 m/s^2 under the influence of a single force of magnitude F_0. What is the ratio of the mass of the second object to that of the first object? (*c*) If the two objects are glued together to form a composite object, what acceleration magnitude will a single force of magnitude F_0 acting on the composite object produce?

Picture the Problem The acceleration of an object is related to its mass and the *net* force acting on it by $F_{\text{net}}=F_0=ma$.

(*a*) Use Newton's second law of motion to relate the acceleration of the object to the net force acting on it:

$$a=\frac{F_{\text{net}}}{m}$$

When $F_{\text{net}}=2F_0$:

$$a=\frac{2F_0}{m}=2a_0$$

Substitute numerical values and evaluate a:

$$a=2\left(3.0\text{ m/s}^2\right)=\boxed{6.0\text{ m/s}^2}$$

(*b*) Let the subscripts 1 and 2 distinguish the two objects. The ratio of the two masses is found from Newton's second law:

$$\frac{m_2}{m_1}=\frac{F_0/a_2}{F_0/a_1}=\frac{a_1}{a_2}=\frac{3.0\text{ m/s}^2}{9.0\text{ m/s}^2}=\boxed{\tfrac{1}{3}}$$

(*c*) The acceleration of the composite object is the net force divided by the total mass $m=m_1+m_2$ of the composite object:

$$a=\frac{F_{\text{net}}}{m}=\frac{F_0}{m_1+m_2}=\frac{F_0/m_1}{1+m_2/m_1}$$
$$=\frac{a_1}{1+\frac{1}{3}}=\tfrac{3}{4}a_1$$

Substitute for a_1 and evaluate a:

$$a=\tfrac{3}{4}\left(3.0\text{ m/s}^2\right)=\boxed{2.3\text{ m/s}^2}$$

32 • A tugboat tows a ship with a constant force of magnitude F_1. The increase in the ship's speed during a 10-s interval is 4.0 km/h. When a second tugboat applies an additional constant force of magnitude F_2 in the same direction, the speed increases by 16 km/h during a 10-s interval. How do the

magnitudes of F_1 and F_2 compare? (Neglect the effects of water resistance and air resistance.)

Picture the Problem The acceleration of an object is related to its mass and the *net* force acting on it by $F_{net} = ma$. Let m be the mass of the ship, a_1 be the acceleration of the ship when the net force acting on it is F_1, and a_2 be its acceleration when the net force is $F_1 + F_2$.

Using Newton's second law, express the net force acting on the ship when its acceleration is a_1:

$$F_1 = ma_1$$

Express the net force acting on the ship when its acceleration is a_2:

$$F_1 + F_2 = ma_2$$

Divide the second of these equations by the first and solve for the ratio F_2/F_1:

$$\frac{F_1 + F_2}{F_1} = \frac{ma_2}{ma_1} \Rightarrow \frac{F_2}{F_1} = \frac{a_2}{a_1} - 1$$

Substitute for the accelerations to determine the ratio of the accelerating forces and solve for F_2 to obtain:

$$\frac{F_2}{F_1} = \frac{\dfrac{16\,\text{km/h}}{10\,\text{s}}}{\dfrac{4.0\,\text{km/h}}{10\,\text{s}}} - 1 = 3 \Rightarrow F_2 = \boxed{3F_1}$$

33 • A single constant force of magnitude 12 N acts on a particle of mass m. The particle starts from rest and travels in a straight line a distance of 18 m in 6.0 s. Find m.

Picture the Problem The mass of the particle is related to its acceleration and the *net* force acting on it by Newton's second law of motion. Because the force is constant, we can use constant-acceleration formulas to calculate the acceleration. Choose a coordinate system in which the +x direction is the direction of motion of the particle.

The mass is related to the net force and the acceleration by Newton's second law:

$$m = \frac{\sum \vec{F}}{\vec{a}} = \frac{F_x}{a_x} \qquad (1)$$

Because the force is constant, the acceleration is constant. Use a constant-acceleration equation to relate the displacement of the particle to it's acceleration:

$$\Delta x = v_{0x}t + \tfrac{1}{2}a_x(\Delta t)^2$$

or, because $v_{0x} = 0$,

$$\Delta x = \tfrac{1}{2}a_x(\Delta t)^2 \Rightarrow a_x = \frac{2\Delta x}{(\Delta t)^2}$$

Substitute for a_x in equation (1) to obtain:

$$m = \frac{F_x(\Delta t)^2}{2\Delta x}$$

Substitute numerical values and evaluate m:

$$m = \frac{(12\,\text{N})(6.0\,\text{s})^2}{2(18\,\text{m})} = \boxed{12\,\text{kg}}$$

34 • A net force of (6.0 N)$\hat{\boldsymbol{i}}$ – (3.0 N)$\hat{\boldsymbol{j}}$ acts on an object of mass 1.5 kg. Find the acceleration $\vec{\boldsymbol{a}}$.

Picture the Problem The acceleration of an object is related to its mass and the *net* force acting on it according to $\vec{\boldsymbol{a}} = \vec{\boldsymbol{F}}_{\text{net}}/m$.

Apply Newton's second law to the object to obtain:

$$\vec{\boldsymbol{a}} = \frac{\vec{\boldsymbol{F}}_{\text{net}}}{m}$$

Substitute numerical values and evaluate $\vec{\boldsymbol{a}}$:

$$\vec{\boldsymbol{a}} = \frac{(6.0\,\text{N})\hat{\boldsymbol{i}} - (3.0\,\text{N})\hat{\boldsymbol{j}}}{1.5\,\text{kg}}$$

$$= \boxed{(4.0\,\text{m/s}^2)\,\hat{\boldsymbol{i}} - (2.0\,\text{m/s}^2)\hat{\boldsymbol{j}}}$$

35 •• **[SSM]** A bullet of mass 1.80 × 10^{-3} kg moving at 500 m/s impacts a tree stump and penetrates 6.00 cm into the wood before coming to rest.
(*a*) Assuming that the acceleration of the bullet is constant, find the force (including direction) exerted by the wood on the bullet. (*b*) If the same force acted on the bullet and it had the same speed but half the mass, how far would it penetrate into the wood?

Picture the Problem Choose a coordinate system in which the +*x* direction is in the direction of the motion of the bullet and use Newton's second law and a constant- acceleration equation to express the relationship between F_{stopping} and the mass of the bullet and its displacement as it is brought to rest in the block of wood.

(*a*) Apply Newton's second law to the bullet to obtain:

$$\sum F_x = F_{\text{stopping}} = ma_x \qquad (1)$$

Use a constant-acceleration equation to relate the bullet's initial and final speeds, acceleration, and stopping distance:

$$v_{\text{f}x}^2 = v_{\text{i}x}^2 + 2a_x\Delta x$$

or, because $v_{\text{f}x} = 0$,

$$0 = v_{\text{i}x}^2 + 2a_x\Delta x \Rightarrow a_x = \frac{-v_{\text{i}x}^2}{2\Delta x}$$

Substitute for a_x in equation (1) to obtain:

$$F_{\text{stopping}} = -m\frac{v_{\text{i}x}^2}{2\Delta x} \qquad (2)$$

Substitute numerical values and evaluate F_{stopping}:

$$F_{\text{stopping}} = -\left(1.80\times10^{-3}\text{ kg}\right)\frac{(500\text{ m/s})^2}{2(6.00\text{ cm})} = \boxed{-3.8\text{ kN}}$$

where the minus sign indicates that F_{stopping} opposes the motion of the bullet.

(*b*) Solving equation (2) for Δx yields:

$$\Delta x = -m\frac{v_{ix}^2}{2F_{\text{stopping}}} \qquad (3)$$

For $m = m'$ and $\Delta x = \Delta x'$:

$$\Delta x' = -m'\frac{v_{ix}^2}{2F_{\text{stopping}}}$$

Evaluate this expression for $m' = \frac{1}{2}m$ to obtain:

$$\Delta x' = -m\frac{v_{ix}^2}{4F_{\text{stopping}}} \qquad (4)$$

Dividing equation (4) by equation (3) yields:

$$\frac{\Delta x'}{\Delta x} = \frac{-m\dfrac{v_{ix}^2}{4F_{\text{stopping}}}}{-m\dfrac{v_{ix}^2}{2F_{\text{stopping}}}} = \frac{1}{2}$$

or

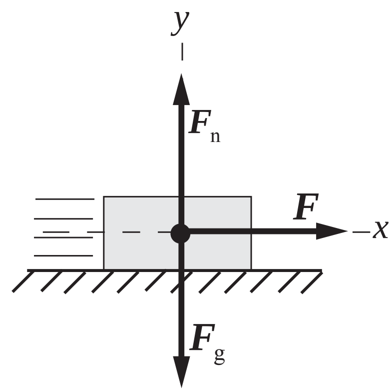
$$\Delta x' = \tfrac{1}{2}\Delta x$$

Substitute numerical values and evaluate $\Delta x'$:

$$\Delta x' = \tfrac{1}{2}(6.00\text{ cm}) = \boxed{3.00\text{ cm}}$$

36 •• A cart on a horizontal, linear track has a fan attached to it. The cart is positioned at one end of the track, and the fan is turned on. Starting from rest, the cart takes 4.55 s to travel a distance of 1.50 m. The mass of the cart plus fan is 355 g. Assume that the cart travels with constant acceleration. (*a*) What is the net force exerted on the cart-fan combination? (*b*) Mass is added to the cart until the total mass of the cart-fan combination is 722 g, and the experiment is repeated. How long does it take for the cart, starting from rest, to travel 1.50 m now? Ignore the effects due to friction.

Picture the Problem Choose the coordinate system shown in the diagram to the right. The force $\vec{F}$ acting on the cart-fan combination is the consequence of the fan blowing air to the left. We can use Newton's second law and a constant-acceleration equation to express the relationship between $\vec{F}$ and the mass of the cart-fan combination and the distance it travels in a given interval of time.



(*a*) Apply Newton's second law to the cart-fan combination to obtain:

$$\sum F_x = F = ma_x \qquad (1)$$

Using a constant-acceleration equation, relate the distance the cart-fan combination travels to its initial speed, acceleration, and the elapsed time:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$

or, because $v_{0x} = 0$,

$$\Delta x = \tfrac{1}{2}a_x(\Delta t)^2 \Rightarrow a_x = \frac{2\Delta x}{(\Delta t)^2}$$

Substitute for a_x in equation (1) to obtain:

$$F = m\frac{2\Delta x}{(\Delta t)^2} \qquad (2)$$

Substitute numerical values and evaluate F:

$$F = (0.355\text{ kg})\frac{2(1.50\text{ m})}{(4.55\text{ s})^2} = 0.05144\text{ N} = \boxed{0.0514\text{ N}}$$

(*b*) Solve equation (2) for Δt to obtain:

$$\Delta t = \sqrt{\frac{2m\Delta x}{F}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \sqrt{\frac{2(0.722\text{ kg})(1.50\text{ m})}{0.05144\text{ N}}} = \boxed{6.49\text{ s}}$$

37 •• A horizontal force of magnitude F_0 causes an acceleration of 3.0 m/s^2 when it acts on an object of mass *m* sliding on a frictionless surface. Find the magnitude of the acceleration of the same object in the circumstances shown in Figure 4-35*a* and 4-35*b*.

Picture the Problem The acceleration of an object is related to its mass and the *net* force acting on it through Newton's second law. Choose a coordinate system in which the direction of $2F_0$ in (*b*) is the positive direction and the direction of the left-most F_0 in (*a*) is the positive direction. Find the resultant force in each case and then find the resultant acceleration.

(*a*) Apply Newton's second law to the object to obtain:

$$a = \frac{F_{net}}{m} \qquad (1)$$

The magnitude of the net force is given by:

$$F_{net} = \sqrt{F_x^2 + F_y^2} = \sqrt{2}F_0$$

Substitute for F_{net} in equation (1) and simplify to obtain:

$$a = \frac{\sqrt{2}F_0}{m} = \sqrt{2}a_0$$

Substitute the numerical value of a_0 and evaluate a:

$$a = \sqrt{2}\left(3.0\,\text{m/s}^2\right) = \boxed{4.2\,\text{m/s}^2}$$

(*b*)The magnitude of net force is given by:

$$F_{net} = \sqrt{F_x^2 + F_y^2} = \sqrt{\left(-F_0 \sin 45°\right)^2 + \left(2F_0 + F_0 \cos 45°\right)^2} = 2.80F_0$$

Substitute for F_{net} in equation (1) and simplify to obtain:

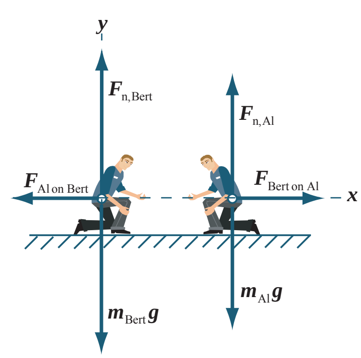
$$a = 2.80\frac{F_0}{m} = 2.80\frac{ma_0}{m} = 2.80a_0$$

Substitute the numerical value of a_0 and evaluate a:

$$a = 2.80\left(3.0\,\text{m/s}^2\right) = \boxed{8.4\,\text{m/s}^2}$$

38 •• Al and Bert stand in the middle of a large frozen lake (frictionless surface). Al pushes on Bert with a force of 20 N for 1.5 s. Bert's mass is 100 kg. Assume that both are at rest before Al pushes Bert. (*a*) What is the speed that Bert reaches as he is pushed away from Al? (*b*) What speed does Al reach if his mass is 80 kg?

Picture the Problem The speed of either Al or Bert can be obtained from their accelerations; in turn, they can be obtained from Newtons second law applied to each person. The free-body diagrams to the right show the forces acting on Al and Bert. The forces that Al and Bert exert on each other are action-and-reaction forces.



(*a*) Apply $\sum F_x = ma_x$ to Bert:

$$-F_{\text{Al on Bert}} = m_{\text{Bert}}a_{\text{Bert}} \Rightarrow a_{\text{Bert}} = \frac{-F_{\text{Al on Bert}}}{m_{\text{Bert}}}$$

Substitute numerical values and evaluate a_{Bert}:

$$a_{\text{Bert}} = \frac{-20\,\text{N}}{100\,\text{kg}} = -0.200\,\text{m/s}^2$$

Using a constant-acceleration equation, relate Bert's speed to his initial speed, speed after 1.5 s, and acceleration:

$$v_x = v_{0x} + a_{\text{Bert,x}}\Delta t$$

Substitute numerical values and evaluate Bert's speed at the end of 1.5 s:

$$v_x = 0 + \left(-0.200\ \text{m/s}^2\right)\left(1.5\ \text{s}\right) = \boxed{-0.30\ \text{m/s}}$$

(*b*) From Newton's 3rd law, an equal but oppositely directed force acts on Al while he pushes Bert. Because the ice is frictionless, Al speeds off in the opposite direction. Apply $\sum F_x = ma_x$ to Al:

$$\sum F_{x,\text{Al}} = F_{\text{Bert on Al},x} = m_{\text{Al}}a_{\text{Al},x}$$

Solving for Al's acceleration yields:

$$a_{\text{Al,x}} = \frac{F_{\text{Bert on Al},x}}{m_{\text{Al}}}$$

Substitute numerical values and evaluate $a_{\text{Al},x}$:

$$a_{\text{Al},x} = \frac{20\ \text{N}}{80\ \text{kg}} = 0.250\ \text{m/s}^2$$

Using a constant-acceleration equation, relate Al's speed to his initial speed, speed after 1.5 s, and acceleration:

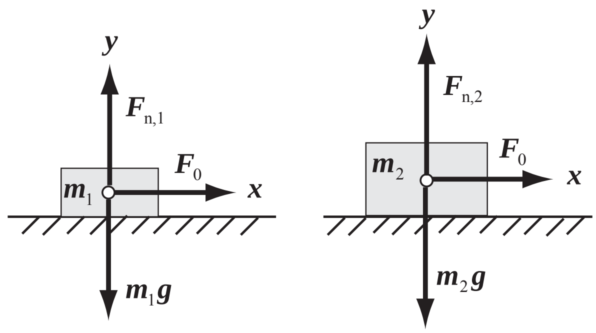
$$v_x = v_{0x} + a_{\text{Al},x}\Delta t$$

Substitute numerical values and evaluate Al's speed at the end of 1.5 s:

$$v_x(1.5\ \text{s}) = 0 + \left(0.250\ \text{m/s}^2\right)\left(1.5\ \text{s}\right) = \boxed{0.38\ \text{m/s}}$$

39 •• If you push a block whose mass is m_1 across a frictionless floor with a horizontal force of magnitude F_0, the block has an acceleration of 12 m/s^2. If you push on a different block whose mass is m_2 with a horizontal force of magnitude F_0, its acceleration is 3.0 m/s^2. (*a*) What acceleration will a horizontal force of magnitude F_0 give to a single block with mass $m_2 - m_1$? (*b*) What acceleration will a horizontal force of magnitude F_0 give to a single block with mass $m_2 + m_1$?

Picture the Problem The free-body diagrams show the forces acting on the two blocks. We can apply Newton's second law to the forces acting on the blocks and eliminate F to obtain a relationship between the masses. Additional applications of Newton's second law to the sum and difference of the masses will lead us to values for the accelerations of these combinations of mass.



(*a*) Apply $\sum F_x = ma_x$ to the two blocks:

$\sum F_{1,x} = F_0 = m_1 a_{1,x}$

and

$\sum F_{2,x} = F_0 = m_2 a_{2,x}$

Eliminate F_0 between the two equations and solve for m_2:

$$m_2 = \frac{a_{1,x}}{a_{2,x}} m_1$$

Substitute numerical values to obtain:

$$m_2 = \frac{12\,\text{m/s}^2}{3.0\,\text{m/s}^2} m_1 = 4.0\, m_1$$

Express the acceleration of an object whose mass is $m_2 - m_1$ when the net force acting on it is F_0:

$$a_x = \frac{F_0}{m_2 - m_1} = \frac{F_0}{4m_1 - m_1} = \frac{F_0}{3m_1} = \tfrac{1}{3} a_{1,x}$$

Substitute numerical values and evaluate a_x:

$$a_x = \tfrac{1}{3}\left(12\,\text{m/s}^2\right) = \boxed{4.0\,\text{m/s}^2}$$

(*b*) Express the acceleration of an object whose mass is $m_2 + m_1$ when the net force acting on it is F_0:

$$a_x = \frac{F_0}{m_2 + m_1} = \frac{F_0}{4m_1 + m_1} = \frac{F_0}{5m_1} = \tfrac{1}{5} a_{1,x}$$

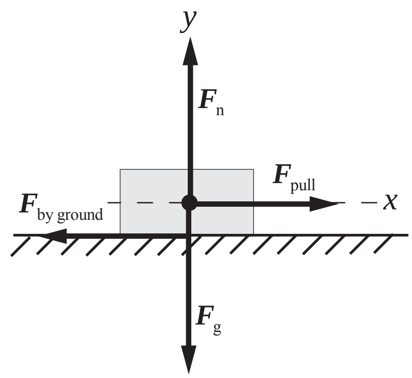
Substitute numerical values and evaluate a_x:

$$a_x = \tfrac{1}{5}\left(12\,\text{m/s}^2\right) = \boxed{2.4\,\text{m/s}^2}$$

40 •• To drag a 75.0-kg log along the ground at constant velocity, your tractor has to pull it with a horizontal force of 250 N. (*a*) Draw the free body diagram of the log. (*b*) Use Newton's laws to determine the force of friction on the log. (*c*) What is the normal force of the ground on the log? (*d*) What horizontal force must you exert if you want to give the log an acceleration of 2.00 m/s^2 assuming the force of friction does not change. Redraw the log's free body diagram for this situation.

Picture the Problem Because the velocity is constant, the net force acting on the log must be zero. Choose a coordinate system in which the positive *x* direction is the direction of motion of the log and apply Newton's second law to the log.

(*a*) The free-body diagram shows the forces acting on the log when it is being dragged in the +*x* direction at constant velocity.



(*b*) Apply $\sum F_x = ma_x$ to the log when it is moving at constant speed:

$$\sum F_x = F_{\text{pull}} - F_{\text{by ground}} = ma_x = 0$$
or
$$F_{\text{by ground}} = F_{\text{pull}}$$

Substitute for F_{pull} and evaluate the force of friction $F_{\text{by ground}}$:

$$F_{\text{by ground}} = F_{\text{pull}} = \boxed{250\text{ N}}$$

(*c*) Apply $\sum F_y = ma_y$ to the log to obtain:

$$\sum F_y = F_{\text{n}} - F_{\text{g}} = ma_y = 0$$
or
$$F_{\text{n}} = F_{\text{g}}$$

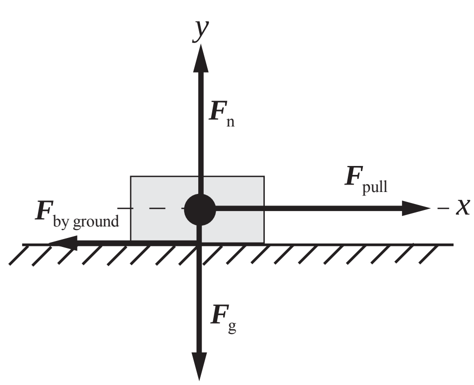
Because the gravitational force is given by $F_{\text{g}} = mg$:

$$F_{\text{n}} = mg$$

Substitute numerical values and evaluate F_{n}:

$$F_{\text{n}} = (75.0\text{ kg})(9.81\text{ m/s}^2) = \boxed{736\text{ N}}$$

(*d*) The free-body diagram shows the forces acting on the log when it is accelerating in the positive *x* direction.



Apply $\sum F_x = ma_x$ to the log when it is accelerating to the right:

$$\sum F_x = F_{\text{pull}} - F_{\text{by ground}} = ma_x$$

Solving for F_{pull} yields:

$$F_{\text{pull}} = ma_x + F_{\text{by ground}}$$

Substitute numerical values and evaluate F_{pull}:

$$F_{\text{pull}} = (75.0\ \text{kg})(2.00\ \text{m/s}^2) + 250\ \text{N} = \boxed{400\ \text{N}}$$

41 •• A 4.0-kg object is subjected to two constant forces, $\vec{F}_1 = (2.0\ \text{N})\,\hat{\boldsymbol{i}} + (-3.0\ \text{N})\,\hat{\boldsymbol{j}}$ and $\vec{F}_2 = (4.0\ \text{N})\,\hat{\boldsymbol{i}} - (11\ \text{N})\,\hat{\boldsymbol{j}}$. The object is at rest at the origin at time $t = 0$. (*a*) What is the object's acceleration? (*b*) What is its velocity at time $t = 3.0$ s? (c) Where is the object at time $t = 3.0$ s?

Picture the Problem The acceleration can be found from Newton's second law. Because both forces are constant, the net force and the acceleration are constant; hence, we can use the constant-acceleration equations to answer questions concerning the motion of the object at various times.

(*a*) Apply Newton's second law to the 4.0-kg object to obtain:

$$\vec{a} = \frac{\vec{F}_{\text{net}}}{m} = \frac{\vec{F}_1 + \vec{F}_2}{m}$$

Substitute numerical values and simplify to evaluate $\vec{a}$:

$$\vec{a} = \frac{(2.0\ \text{N})\hat{\boldsymbol{i}} + (-3.0\ \text{N})\hat{\boldsymbol{j}} + (4.0\ \text{N})\hat{\boldsymbol{i}} + (-11\ \text{N})\hat{\boldsymbol{j}}}{4.0\ \text{kg}} = \frac{(6.0\ \text{N})\hat{\boldsymbol{i}} + (-14\ \text{N})\hat{\boldsymbol{j}}}{4.0\ \text{kg}}$$
$$= \boxed{(1.5\ \text{m/s}^2)\hat{\boldsymbol{i}} + (-3.5\ \text{m/s}^2)\hat{\boldsymbol{j}}}$$

(*b*) Using a constant-acceleration equation, express the velocity of the object as a function of time:

$$\vec{v} = \vec{v}_0 + \vec{a}t$$

Substitute numerical values and evaluate $\vec{v}(3.0\ \text{s})$:

$$\vec{v}(3.0\ \text{s}) = \left[(1.5\ \text{m/s}^2)\hat{\boldsymbol{i}} + (-3.5\ \text{m/s}^2)\hat{\boldsymbol{j}}\right](3.0\ \text{s}) = (4.5\ \text{m/s})\hat{\boldsymbol{i}} + (-10.5\ \text{m/s})\hat{\boldsymbol{j}}$$
$$= \boxed{(4.5\ \text{m/s})\hat{\boldsymbol{i}} + (-11\ \text{m/s})\hat{\boldsymbol{j}}}$$

(*c*) Express the position of the object in terms of its average velocity:

$$\vec{r} = \vec{v}_{\text{av}}t = \frac{\vec{v}_0 + \vec{v}}{2}t = \tfrac{1}{2}\vec{v}t$$

Substitute for $\vec{v}$ and evaluate this expression at $t = 3.0$ s:

$$\vec{r}(3.0\ \text{s}) = \tfrac{1}{2}\left[(4.5\ \text{m/s})\hat{\boldsymbol{i}} + (-10.5\ \text{m/s})\hat{\boldsymbol{j}}\right](3.0\ \text{s}) = (6.75\ \text{m})\hat{\boldsymbol{i}} + (-15.8\ \text{m})\hat{\boldsymbol{j}}$$
$$= \boxed{(6.8\ \text{m})\hat{\boldsymbol{i}} + (-16\ \text{m})\hat{\boldsymbol{j}}}$$

Mass and Weight

42 • On the moon, the acceleration due to gravity is only about 1/6 of that on Earth. An astronaut, whose weight on Earth is 600 N, travels to the lunar surface. His mass, as measured on the moon, will be (*a*) 600 kg, (*b*) 100 kg, (*c*) 61.2 kg, (*d*) 9.81 kg, (*e*) 360 kg.

Picture the Problem The mass of the astronaut is independent of gravitational fields and will be the same on the moon or, for that matter, out in deep space.

Express the mass of the astronaut in terms of his weight on Earth and the gravitational field at the surface of Earth:

$$m = \frac{w_{\text{earth}}}{g_{\text{earth}}} = \frac{600\,\text{N}}{9.81\,\text{N/kg}} = 61.2\,\text{kg}$$

and $\boxed{(c)}$ is correct.

43 • Find the weight of a 54-kg student in (*a*) newtons and (*b*) pounds.

Picture the Problem The weight of an object is related to its mass and the gravitational field through $F_g = mg$.

(*a*) The weight of the student is:

$$w = mg = (54\,\text{kg})(9.81\,\text{N/kg}) = 530\,\text{N} = \boxed{5.3\times10^{2}\ \text{N}}$$

(*b*) Convert newtons to pounds:

$$w = \frac{530\,\text{N}}{4.45\,\text{N/lb}} = 119\,\text{lb} \approx \boxed{1.2\times10^{2}\ \text{lb}}$$

44 • Find the mass of a 165-lb engineer in kilograms.

Picture the Problem The mass of an object is related to its weight and the gravitational field.

Convert the weight of the man into newtons:

$$165\,\text{lb} = (165\,\text{lb})(4.45\,\text{N/lb}) = 734\,\text{N}$$

Calculate the mass of the man from his weight and the gravitational field:

$$m = \frac{w}{g} = \frac{734\,\text{N}}{9.81\,\text{N/kg}} = \boxed{74.8\,\text{kg}}$$

45 •• **[SSM]** To train astronauts to work on the moon, where the acceleration due to gravity is only about 1/6 of that on Earth, NASA submerges them in a tank of water. If an astronaut, who is carrying a backpack, air conditioning unit, oxygen supply, and other equipment, has a total mass of 250 kg, determine the following quantities. (*a*) her weight, including her backpack, etc., on Earth, (*b*) her weight on the moon, (*c*) the required upward

buoyancy force of the water during her training for the moon's environment on Earth.

Picture the Problem We can use the relationship between weight (gravitational force) and mass, together with the given information about the acceleration due to gravity on the moon, to find the astronaut's weight on Earth and on the moon.

(*a*) Her weight on Earth is the product of her mass and the gravitational field at the surface of Earth:

$$w_{\text{Earth}} = mg$$

Substitute numerical values and evaluate *w*:

$$w_{\text{Earth}} = (250\text{ kg})(9.81\text{ m/s}^2) = 2.453\text{ kN}$$
$$= \boxed{2.45\text{ kN}}$$

(*b*) Her weight on the moon is the product of her mass and the gravitational field at the surface of the moon:

$$w_{\text{moon}} = mg_{\text{moon}} = \tfrac{1}{6}mg = \tfrac{1}{6}w_{\text{earth}}$$

Substitute for her weight on Earth and evaluate her weight on the moon:

$$w_{\text{moon}} = \tfrac{1}{6}(2.453\text{ kN}) = \boxed{409\text{ N}}$$

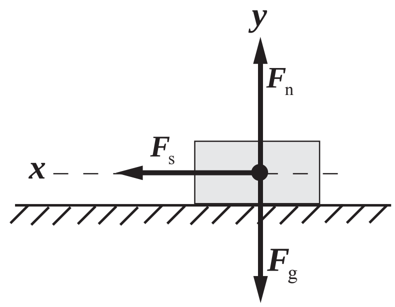
(*c*) The required upward buoyancy force of the water equals the difference between her weight on Earth and on the moon:

$$w_{\text{buoyancy}} = w_{\text{Earth}} - w_{\text{moon}}$$
$$= 2.45\text{ kN} - 0.41\text{ kN}$$
$$= \boxed{2.04\text{kN}}$$

46 •• It is the year 2075 and space travel is common. A physics professor brings his favorite teaching demonstration with him to the moon. The apparatus consists of a very smooth horizontal (frictionless) table and an object to slide on it. On Earth, when the professor attaches a spring (spring constant 50 N/m) to the object and pulls horizontally so the spring stretches 2.0 cm, the object accelerates at1.5 m/s^2. (*a*) Draw the free-body diagram of the object and use it and Newton's laws to determine the object's mass. (*b*) What would the object's acceleration be under identical conditions on the moon?

Picture the Problem The forces acting on the object are the normal force exerted by the table, the gravitational force exerted by Earth, and the force exerted by the stretched spring.

(*a*) The free-body diagram shown to the right assumes that the spring has been stretched to the right. Hence the force that the spring exerts on the object is to the left. Note that the +*x* direction has been chosen to be in the same direction as the force exerted by the spring.



Apply $\sum F_x = ma_x$ to the object to obtain:

$$\sum F_x = F_s = ma_x \Rightarrow m = \frac{F_s}{a_x} \quad (1)$$

The force exerted by the spring on the object is given by:

$$F_s = k\Delta x$$

where Δx is the amount by which the spring has been stretched or compressed and k is the force constant.

Substituting for F_s in equation (1) yields:

$$m = \frac{k\Delta x}{a_x}$$

Substitute numerical values and evaluate m:

$$m = \frac{(50\ \text{N/m})(2.0\ \text{cm})}{1.5\ \text{m/s}^2} = \boxed{0.67\ \text{kg}}$$

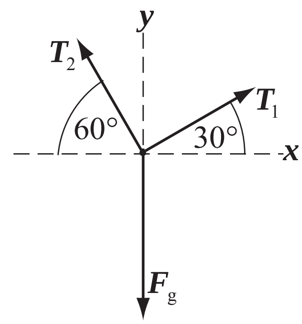
(*b*) Because the object's mass is the same on the moon as on Earth and the force exerted by the spring is the same, its acceleration on the moon would be the same as on Earth.

Free-Body Diagrams: Static Equilibrium

47 • A 35.0-kg traffic light is supported by two wires as in Figure 4-36. (*a*) Draw the light's free-body diagram and use it to answer the following question qualitatively: Is the tension in wire 2 greater than or less than the tension in wire 1? (*b*) Prove your answer by applying Newton's laws and solving for the two tensions.

Picture the Problem Because the traffic light is not accelerating, the *net* force acting on it must be zero; i.e., $\vec{T}_1 + \vec{T}_2 + \vec{F}_g = 0$.

(*a*) Construct a free-body diagram showing the forces acting on the support point:



Apply $\sum F_x = ma_x$ to the support point:

$$T_1 \cos 30° - T_2 \cos 60° = ma_x = 0$$

Solve for T_2 in terms of T_1:

$$T_2 = \frac{\cos 30°}{\cos 60°} T_1 = 1.732 T_1 \qquad (1)$$

Thus T_2 is greater than T_1.

(*b*) Apply $\sum F_y = ma_x$ to the support point:

$$T_1 \sin 30° + T_2 \sin 60° - F_g = ma_y = 0$$

Substitute for T_2 to obtain:

$$\tfrac{1}{2} T_1 + \tfrac{\sqrt{3}}{2}(1.732 T_1) - mg = 0$$

Solving for T_1 gives:

$$T_1 = \frac{mg}{2.000}$$

Substitute numerical values and evaluate T_1:

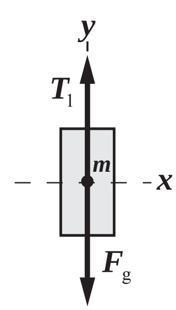
$$T_1 = \frac{(35.0\,\text{kg})(9.81\,\text{m/s}^2)}{2.000} = \boxed{172\,\text{N}}$$

From equation (1) we have:

$$T_2 = 1.732 T_1 = (1.732)(172\,\text{N}) = \boxed{298\,\text{N}}$$

48 • A 42.6-kg lamp is hanging from wires as shown in Figure 4-37. The ring has negligible mass. The tension T_1 in the vertical wire is (*a*) 209 N, (*b*) 418 N, (*c*) 570 N, (*d*) 360 N, (*e*) 730 N.

Picture the Problem From the figure, it is clear that T_1 supports the full weight of the lamp. Draw a free-body diagram showing the forces acting on the lamp and apply $\sum F_y = 0$.



Apply $\sum F_y = 0$ to the lamp to obtain:

$$\sum F_y = T_1 - F_g = 0$$

Solve for T_1 and substitute for F_g to obtain:

$$T_1 = F_g = mg$$

Substitute numerical values and evaluate T_1:

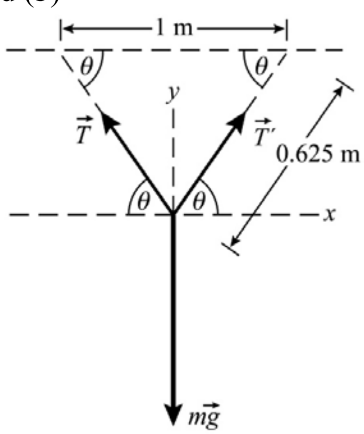
$$T_1 = (42.6\,\text{kg})(9.81\,\text{m/s}^2) = 418\,\text{N}$$

and $\boxed{(b)}$ is correct.

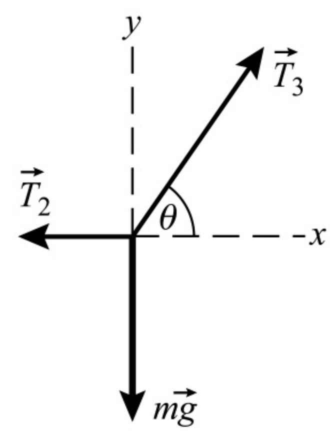
49 •• [SSM] In Figure 4-38*a*, a 0.500-kg block is suspended at the midpoint of a 1.25-m-long string. The ends of the string are attached to the ceiling at points separated by 1.00 m. (*a*) What angle does the string make with the ceiling? (*b*) What is the tension in the string? (*c*) The 0.500-kg block is removed and two 0.250-kg blocks are attached to the string such that the lengths of the three string segments are equal (Figure 4-38*b*). What is the tension in each segment of the string?

Picture the Problem The free-body diagrams for Parts (*a*), (*b*), and (*c*) are shown below. In both cases, the block is in equilibrium under the influence of the forces and we can use Newton's second law of motion and geometry and trigonometry to obtain relationships between θ and the tensions.

(*a*) and (*b*)



(*c*)



(*a*) Referring to the free-body diagram for Part (*a*), use trigonometry to determine θ:

$$\theta = \cos^{-1}\left(\frac{0.50\,\text{m}}{0.625\,\text{m}}\right) = 36.9° = \boxed{37°}$$

(*b*) Noting that $T = T'$, apply $\sum F_y = ma_y$ to the 0.500-kg block and solve for the tension T:

$$2T\sin\theta - mg = 0 \text{ because } a = 0$$

and

$$T = \frac{mg}{2\sin\theta}$$

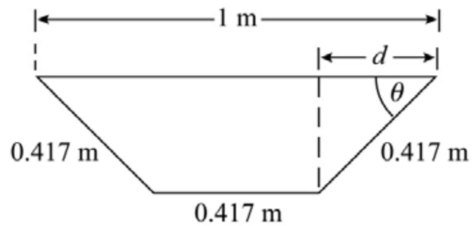
Substitute numerical values and evaluate T:

$$T = \frac{(0.500\,\text{kg})(9.81\,\text{m/s}^2)}{2\sin 36.9°} = \boxed{4.1\,\text{N}}$$

(*c*) The length of each segment is:

$$\frac{1.25\,\text{m}}{3} = 0.41667\,\text{m}$$

Find the distance *d*:



$$d = \frac{1.00\,\text{m} - 0.41667\text{m}}{2} = 0.29167\,\text{m}$$

Express θ in terms of *d* and solve for its value:

$$\theta = \cos^{-1}\left(\frac{d}{0.417\,\text{m}}\right) = \cos^{-1}\left(\frac{0.2917\,\text{m}}{0.4167\,\text{m}}\right) = 45.57°$$

Apply $\sum F_y = ma_y$ to the 0.250-kg block:

$$T_3 \sin\theta - mg = 0 \Rightarrow T_3 = \frac{mg}{\sin\theta}$$

Substitute numerical values and evaluate T_3:

$$T_3 = \frac{(0.250\,\text{kg})(9.81\,\text{m/s}^2)}{\sin 45.57°} = 3.434\text{ N} = \boxed{3.4\,\text{N}}$$

Apply $\sum F_x = ma_x$ to the 0.250-kg block and solve for the tension T_2:

$T_3 \cos\theta - T_2 = 0$ since $a = 0$.
and
$T_2 = T_3 \cos\theta$

Substitute numerical values and evaluate T_2:

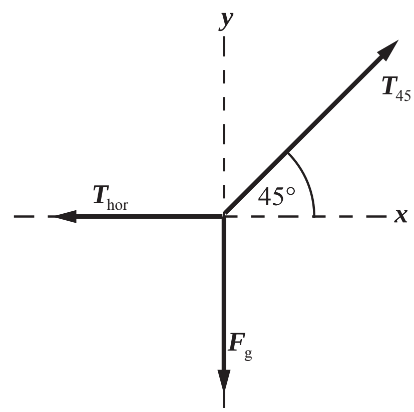
$$T_2 = (3.434\,\text{N})\cos 45.57° = \boxed{2.4\,\text{N}}$$

By symmetry:

$$T_1 = T_3 = \boxed{3.4\,\text{N}}$$

50 •• A ball weighing 100 N is shown suspended from a system of cords (Figure 4-39). What are the tensions in the horizontal and angled cords?

Picture the Problem The suspended body is in equilibrium under the influence of the forces $\vec{T}_{hor}$, $\vec{T}_{45}$, and $\vec{F}_g$. That is, $\vec{T}_{hor} + \vec{T}_{45} + \vec{F}_g = 0$. Draw the free-body diagram of the forces acting on the knot just above the 100-N body. Choose a coordinate system with the positive x direction to the right and the positive y direction upward. Apply the conditions for translational equilibrium to determine the tension in the horizontal cord.



Apply $\sum F_y = ma_y$ to the knot: $\sum F_y = T_{45}\sin 45° - F_g = ma_y = 0$

Solving for T_{45} yields: $T_{45} = \dfrac{F_g}{\sin 45°} = \dfrac{100\ \text{N}}{\sin 45°} = \boxed{141\ \text{N}}$

Apply $\sum F_x = ma_x$ to the knot: $\sum F_x = T_{45}\cos 45° - T_{hor} = ma_x = 0$

Solving for T_{hor} gives: $T_{hor} = T_{45}\cos 45° = (141\ \text{N})\cos 45° = \boxed{100\ \text{N}}$

51 •• **[SSM]** A 10-kg object on a frictionless table is subjected to two horizontal forces, $\vec{F}_1$ and $\vec{F}_2$, with magnitudes $F_1 = 20$ N and $F_2 = 30$ N, as shown in Figure 4-40. Find the third force $\vec{F}_3$ that must be applied so that the object is in static equilibrium.

Picture the Problem The acceleration of *any* object is directly proportional to the *net* force acting on it. Choose a coordinate system in which the positive x direction is the same as that of $\vec{F}_1$ and the positive y direction is to the right. Add the two forces to determine the net force and then use Newton's second law to find the acceleration of the object. If $\vec{F}_3$ brings the system into equilibrium, it must be true that $\vec{F}_3 + \vec{F}_1 + \vec{F}_2 = 0$.

Express $\vec{F}_3$ in terms of $\vec{F}_1$ and $\vec{F}_2$: $\vec{F}_3 = -\vec{F}_1 - \vec{F}_2$ (1)

Express $\vec{F}_1$ and $\vec{F}_2$ in unit vector notation:

$$\vec{F}_1 = (20\,\text{N})\hat{i}$$

and

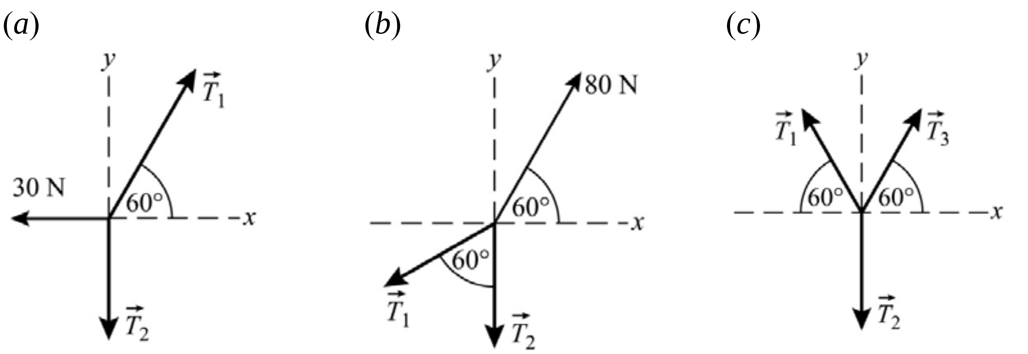
$$\vec{F}_2 = \{(-30\,\text{N})\sin 30°\}\hat{i} + \{(30\,\text{N})\cos 30°\}\hat{j} = (-15\,\text{N})\hat{i} + (26\,\text{N})\hat{j}$$

Substitute for $\vec{F}_1$ and $\vec{F}_2$ in equation (1) and simplify to obtain:

$$\vec{F}_3 = -(20\,\text{N})\hat{i} - [(-15\,\text{N})\hat{i} + (26\,\text{N})\hat{j}] = \boxed{(-5.0\,\text{N})\hat{i} + (-26\,\text{N})\hat{j}}$$

52 •• For the systems to be in equilibrium in Figure 4-41*a*, Figure 4-41*b*, and Figure 4-41*c* find the unknown tensions and masses.

Picture the Problem The free-body diagrams for the systems in equilibrium are shown below. Apply the conditions for translational equilibrium to find the unknown tensions.



(*a*) Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the knot above the suspended mass to obtain:

$$\sum F_x = T_1 \cos 60° - 30\text{ N} = 0 \quad (1)$$

and

$$\sum F_y = T_1 \sin 60° - T_2 = 0 \quad (2)$$

Solving equation (1) for T_1 yields:

$$T_1 = \frac{30\text{ N}}{\cos 60°} = \boxed{60\text{ N}}$$

Solving equation (2) for T_2 yields:

$$T_2 = T_1 \sin 60° = (60\text{ N})\sin 60° = 51.96\text{ N} = \boxed{52\text{ N}}$$

Because T_2 is the weight of the object whose mass is m:

$$T_2 = F_g = mg \Rightarrow m = \frac{T_2}{g}$$

Substitute numerical values and evaluate m:

$$m = \frac{51.96\ \text{N}}{9.81\ \text{m/s}^2} = \boxed{5.3\ \text{kg}}$$

(*b*) Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the knot above the suspended mass to obtain:

$$\sum F_x = (80\ \text{N})\cos 60° - T_1 \sin 60° = 0$$
and
$$\sum F_y = (80\ \text{N})\sin 60° - T_2 - T_1 \cos 60° = 0$$

Solving the first of these equations for T_1 yields:

$$T_1 = \frac{(80\ \text{N})\cos 60°}{\sin 60°} = 46.19\ \text{N}$$
$$= \boxed{46\ \text{N}}$$

Solving the second of these equations for T_2 yields:

$$T_2 = (80\ \text{N})\sin 60° - T_1 \cos 60°$$

Substitute numerical values and evaluate T_2:

$$T_2 = (80\ \text{N})\sin 60° - (46.19\ \text{N})\cos 60°$$
$$= 46.19\ \text{N} = \boxed{46\ \text{N}}$$

Because T_2 is the weight of the object whose mass is m:

$$T_2 = F_\text{g} = mg \Rightarrow m = \frac{T_2}{g}$$

Substitute numerical values and evaluate m:

$$m = \frac{46.19\ \text{N}}{9.81\ \text{m/s}^2} = \boxed{4.7\ \text{kg}}$$

(*c*) Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the knot above the suspended mass to obtain:

$$\sum F_x = -T_1 \cos 60° + T_3 \cos 60° = 0$$
and
$$\sum F_y = T_1 \sin 60° + T_3 \sin 60° - F_\text{g} = 0$$

Solving the first of these equations for T_1 yields:

$$T_1 = T_3$$

Solving the second of these equations for T_1 yields:

$$T_1 = T_3 = \frac{F_\text{g}}{2\sin 60°} = \frac{mg}{2\sin 60°}$$

Substitute numerical values and evaluate T_1 and T_3:

$$T_1 = T_3 = \frac{(6.0\ \text{kg})(9.81\ \text{m/s}^2)}{2\sin 60°} = 33.98\ \text{N}$$
$$= \boxed{34\ \text{N}}$$

Because $T_2 = F_\text{g}$:

$$T_2 = (6.0\ \text{kg})(9.81\ \text{m/s}^2) = 58.9\ \text{N}$$
$$= \boxed{59\ \text{N}}$$

Because the effect of the pulley is to change the direction T_1 acts, T_1 is the weight of the object whose mass is m:

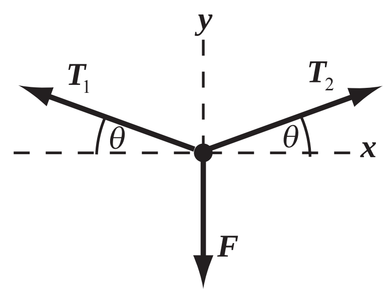
$$T_1 = mg \Rightarrow m = \frac{T_1}{g}$$

Substitute numerical values and evaluate m:

$$m = \frac{33.98\ \text{N}}{9.81\ \text{m/s}^2} = \boxed{3.5\ \text{kg}}$$

53 •• Your car is stuck in a mud hole. You are alone, but you have a long, strong rope. Having studied physics, you tie the rope tautly to a telephone pole and pull on it sideways, as shown in Figure 4-42. (*a*) Find the force exerted by the rope on the car when the angle θ is 3.00º and you are pulling with a force of 400 N but the car does not move. (*b*) How strong must the rope be if it takes a force of 600 N to move the car when θ is 4.00º?

Picture the Problem Construct the free-body diagram for that point in the rope at which you exert the force $\vec{F}$ and choose the coordinate system shown in the free-body diagram. We can apply Newton's second law to the rope to relate the tension to F.



(*a*) Noting that $T_1 = T_2 = T$ and that the car's acceleration is zero, apply $\sum F_y = ma_y$ to the car:

$$2T\sin\theta - F = ma_y = 0 \Rightarrow T = \frac{F}{2\sin\theta}$$

Substitute numerical values and evaluate T:

$$T = \frac{400\ \text{N}}{2\sin 3.00°} = \boxed{3.82\ \text{kN}}$$

(*b*) Proceed as in Part (*a*) to obtain:

$$T = \frac{600\ \text{N}}{2\sin 4.00°} = \boxed{4.30\ \text{kN}}$$

54 ••• Balloon arches are often seen at festivals or celebrations; they are made by attaching helium-filled balloons to a rope that is fixed to the ground at each end. The lift from the balloons raises the structure into the arch shape. Figure 4-43*a* shows the geometry of such a structure: N balloons are attached at equally spaced intervals along a massless rope of length L, which is attached to two supports at its ends. Each balloon provides a lift force F. The horizontal and vertical coordinates of the point on the rope where the ith balloon is attached are x_i and y_i, and T_i is the tension in the ith segment. (Note segment 0 is the segment between the point of attachment and the first balloon, and segment N is the segment between the last balloon and the other point of attachment). (*a*) Figure 4-43*b* shows a free-body diagram for the ith balloon. From this diagram, show that the horizontal component of the force T_i (call it T_H) is the same for all the

string segments. (*b*) By considering the vertical component of the forces, use Newton's laws to derive the following relationship between the tension in the *i*th and (i – 1)th segments: $T_{i-1}\sin\theta_{i-1} - T_i\sin\theta_i = F$ (*b*) Show that $\tan\theta_0 = -\tan\theta_{N+1} = NF/2T_H$. (*c*) From the diagram and the two expressions above, show that $\tan\theta_i = (N - 2i)F/2T_H$ and that $x_i = \dfrac{L}{N+1}\sum_{j=0}^{i-1}\cos\theta_j$,
$y_i = \dfrac{L}{N+1}\sum_{j=0}^{i-1}\sin\theta_j$.

Picture the Problem (*a*) Applying $\sum F_x = 0$ to the balloon shown in Figure 4-43 (*b*) will show that the horizontal component of the force T_i is the same for all string segments. In Part (*b*) we can apply $\sum F_y = 0$ to obtain the given expression for *F*. In (*c*) we can use a symmetry argument to find an expression for tan θ_0. Finally, in (*d*) we can use our results obtained in (*a*) and (*b*) to express x_i and y_i.

(*a*) Applying $\sum F_x = 0$ to the balloon shown in Figure 4-43 (*b*) gives:

$$T_i\cos\theta_i - T_{i-1}\cos\theta_{i-1} = 0$$

Because $T_H = T_i\cos\theta_i$:

$$T_H - T_{i-1}\cos\theta_{i-1} = 0 \Rightarrow T_H = T_{i-1}\cos\theta_{i-1}$$

independently of the string segment.

(*b*) Apply $\sum F_y = 0$ to the balloon shown in Figure 4-43 (*b*) gives:

$$F + T_i\sin\theta_i - T_{i-1}\sin\theta_{i-1} = 0$$

Solving for *F* yields:

$$F = \boxed{T_{i-1}\sin\theta_{i-1} - T_i\sin\theta_i}$$

(*c*) By symmetry, each support must balance half of the force acting on the entire arch. Therefore, the vertical component of the force on the support must be *NF*/2. The horizontal component of the tension must be T_H. Express tanθ_0 in terms of *NF*/2 and T_H:

$$\tan\theta_0 = \frac{NF/2}{T_H} = \frac{NF}{2T_H}$$

By symmetry, $\theta_{N+1} = -\theta_0$. Therefore, because the tangent function is odd:

$$\tan\theta_0 = \boxed{-\tan\theta_{N+1} = \frac{NF}{2T_H}}$$

(d) Using $T_H = T_i \cos\theta_i = T_{i-1}\cos\theta_{i-1}$, divide both sides of the result in (b) by T_H and simplify to obtain:

$$\frac{F}{T_H} = \frac{T_{i-1}\sin\theta_{i-1}}{T_{i-1}\cos\theta_{i-1}} - \frac{T_i \sin\theta_i}{T_i \cos\theta_i} = \tan\theta_{i-1} - \tan\theta_i$$

Using this result, express $\tan\theta_1$:

$$\tan\theta_1 = \tan\theta_0 - \frac{F}{T_H}$$

Substitute for $\tan\theta_0$ from (a):

$$\tan\theta_1 = \frac{NF}{2T_H} - \frac{F}{T_H} = (N-2)\frac{F}{2T_H}$$

Generalize this result to obtain:

$$\tan\theta_i = \boxed{(N-2i)\frac{F}{2T_H}}$$

Express the length of rope between two balloons:

$$\ell_{\substack{\text{between}\\\text{balloons}}} = \frac{L}{N+1}$$

Express the horizontal coordinate of the point on the rope where the ith balloon is attached, x_i, in terms of x_{i-1} and the length of rope between two balloons:

$$x_i = x_{i-1} + \frac{L}{N+1}\cos\theta_{i-1}$$

Sum over all the coordinates to obtain:

$$\boxed{x_i = \frac{L}{N+1}\sum_{j=0}^{i-1}\cos\theta_j}$$

Proceed similarly for the vertical coordinates to obtain:

$$\boxed{y_i = \frac{L}{N+1}\sum_{j=0}^{i-1}\sin\theta_j}$$

55 ••• (a) Consider a numerical solution to Problem 54. Write a **spreadsheet** program to make a graph of the shape of a balloon arch. Use the following parameters: $N = 10$ balloons each providing a lift force $F = 1.0$ N and each attached to a rope length $L = 11$ m, with a horizontal component of tension $T_H = 10$ N. How far apart are the two points of attachment? How high is the arch at its highest point? (b) Note that we haven't specified the spacing between the supports—it is determined by the other parameters. Vary T_H while keeping the other parameters the same until you create an arch that has a spacing of 8.0 m between the supports. What is T_H then? As you increase T_H, the arch should get flatter and more spread out. Does your spreadsheet model show this?

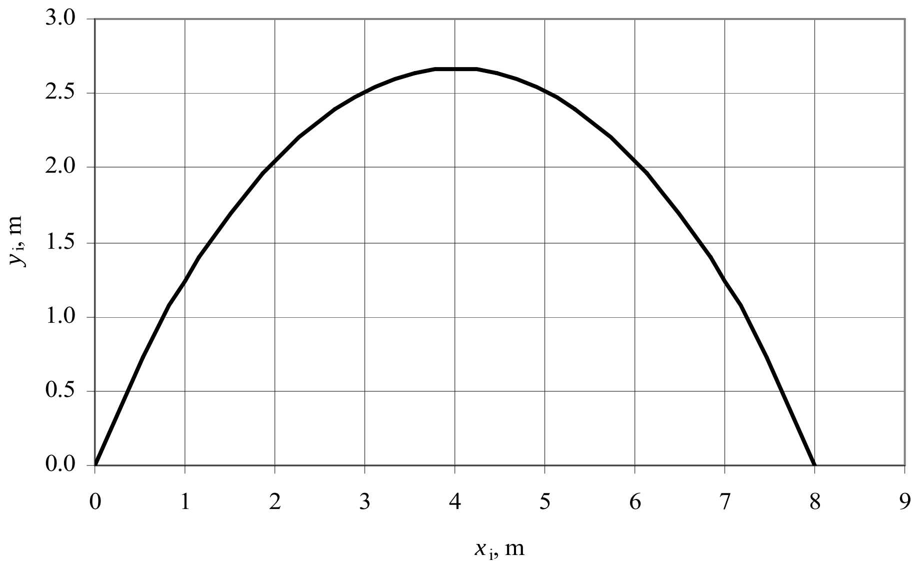
Picture the Problem

(*a*) A spreadsheet program is shown below. The formulas used to calculate the quantities in the columns are as follows:

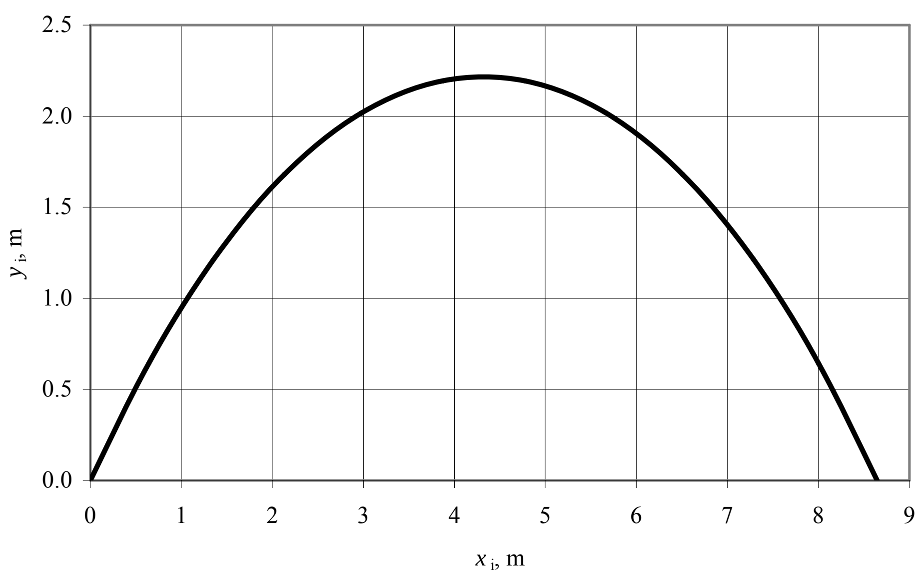
Cell	Content/Formula	Algebraic Form
C7	($B$2−2*B7)/(2*$B$4)	$(N-2\mathrm{i})\dfrac{F}{2T_{\mathrm{H}}}$
D7	SIN(ATAN(C7))	$\sin\left(\tan^{-1}\theta_{\mathrm{i}}\right)$
E7	COS(ATAN(C7))	$\cos\left(\tan^{-1}\theta_{\mathrm{i}}\right)$
F7	0.000	0
G7	0.000	0
F8	F7+$B$1/($B$2+1)*E7	$x_{\mathrm{i}-1}+\dfrac{L}{N+1}\cos\theta_{\mathrm{i}-1}$
G8	G7+$B$1/($B$2+1)*D7	$y_{\mathrm{i}-1}+\dfrac{L}{N+1}\cos\theta_{\mathrm{i}-1}$

	A	B	C	D	E	F	G
1	$L=$	11	m				
2	$N=$	10					
3	$F=$	1	N				
4	$T_{\mathrm{H}}=$	3.72	N				
5							
6		i	$\tan\theta_{\mathrm{i}}$	$\sin\theta_{\mathrm{i}}$	$\cos\theta_{\mathrm{i}}$	x_{i}	y_{i}
7		0	1.344	0.802	0.597	0.000	0.000
8		1	1.075	0.732	0.681	0.543	0.729
9		2	0.806	0.628	0.778	1.162	1.395
10		3	0.538	0.474	0.881	1.869	1.966
14		5	0.000	0.000	1.000	3.548	2.632
15		6	−0.269	−0.260	0.966	4.457	2.632
19		10	−1.344	−0.802	0.597	7.462	0.729
20		11				8.005	0.000

(b) A horizontal component of tension 3.72 N gives a spacing of 8 m. At this spacing, the arch is 2.63 m high, tall enough for someone to walk through. A graph of y_i as a function of x_i for the conditions specified follows:



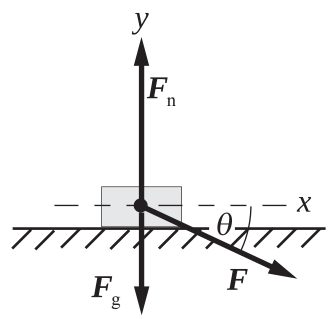
The spreadsheet graph shown below shows that changing the horizontal component of tension to 5 N broadens the arch and decreases its height as predicted by our mathematical model.



Free-Body Diagrams: Inclined Planes and the Normal Force

56 • A large box whose mass is 20.0 kg rests on a frictionless floor. A mover pushes on the box with a force of 250 N at an angle 35.0º below the horizontal. Draw the box's free body diagram and use it to determine the acceleration of the box.

Picture the Problem The free-body diagram shows the forces acting on the box as the man pushes it across the frictionless floor. We can apply Newton's second law to the box to find its acceleration.



Apply $\sum F_x = ma_x$ to the box:

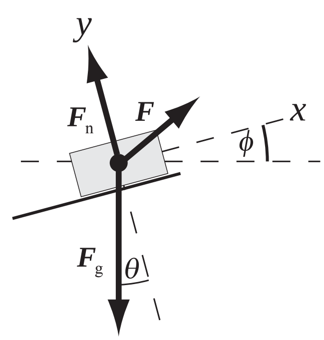
$$F\cos\theta = ma_x \Rightarrow a_x = \frac{F\cos\theta}{m}$$

Substitute numerical values and evaluate a_x:

$$a_x = \frac{(250\,\text{N})\cos 35.0°}{20.0\,\text{kg}} = \boxed{10.2\,\text{m/s}^2}$$

57 • A 20-kg box rests on a frictionless ramp with a 15.0º slope. The mover pulls on a rope attached to the box to pull it up the incline (Figure 4-44). If the rope makes an angle of 40.0º with the horizontal, what is the smallest force *F* the mover will have to exert to move the box up the ramp?

Picture the Problem The free-body diagram shows the forces acting on the box as the man pushes it up the frictionless incline. We can apply Newton's second law to the box to determine the smallest force that will move it up the incline at constant speed.



Letting $F_{min} = F$, apply $\sum F_x = ma_x$ to the box as it moves up the incline with constant speed:

$$F_{min}\cos(\phi - \theta) - F_g\sin\theta = 0$$

Solve for F_{min} to obtain:

$$F_{min} = \frac{F_g\sin\theta}{\cos(\phi - \theta)}$$

Because $F_g = mg$:

$$F_{min} = \frac{mg\sin\theta}{\cos(\phi - \theta)}$$

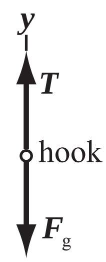
Substitute numerical values and evaluate F_{min}:

$$F_{min} = \frac{(20.0\,\text{kg})(9.81\,\text{m/s}^2)\sin 15°}{\cos(40.0° - 15.0°)} = \boxed{56.0\,\text{N}}$$

58 • In Figure 4-45, the objects are attached to spring scales calibrated in newtons. Give the readings of the balance(s) in each case, assuming that both the scales and the strings are massless.

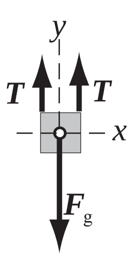
Picture the Problem The balance(s) indicate the tension in the string(s). Draw free-body diagrams for each of these systems and apply the condition(s) for equilibrium.

(*a*)



(*b*)

(*c*)



(*d*)

(*a*) Apply $\sum F_y = 0$ to the hook to obtain:

$\sum F_y = T - F_g = 0$
or, because $F_g = mg$,
$T = mg$

Substitute numerical values and evaluate T:

$$T = (10\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{98\,\text{N}}$$

(*b*) Apply $\sum F_x = 0$ to the balance to obtain:

$\sum F_x = T - T' = 0$
or, because $T' = mg$,
$T = T' = mg$

Substitute numerical values and evaluate T and T':

$$T = T' = (10\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{98\,\text{N}}$$

(c) Apply $\sum F_y = 0$ to the suspended object to obtain:

$$\sum F_y = 2T - F_g = 0$$

or, because $F_g = mg$,

$$2T - mg = 0 \Rightarrow T = \tfrac{1}{2}mg$$

Substitute numerical values and evaluate T:

$$T = \tfrac{1}{2}(10\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{49\,\text{N}}$$

(d) Apply $\sum F_x = 0$ to the balance to obtain:

$$\sum F_x = T - T' = 0$$

or, because $T' = mg$,

$$T = T' = mg$$

Substitute numerical values and evaluate T and T':

$$T = T' = (10\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{98\,\text{N}}$$

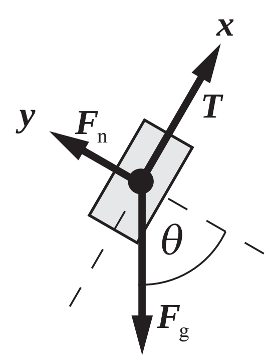
Remarks: Note that (*a*), (*b*), and (*d*) give the same answers … a rather surprising result until one has learned to draw FBDs and apply the conditions for translational equilibrium.

59 •• A box is held in position on a frictionless incline by a cable (Figure 4-46). (a) If $\theta = 60^\circ$ and $m = 50$ kg, find the tension in the cable and the normal force exerted by the incline. (b) Find the tension as a function of θ and m, and check your result for plausibility in the special cases when $\theta = 0^\circ$ and $\theta = 90^\circ$.

Picture the Problem Because the box is held in place (is in equilibrium) by the forces acting on it, we know that

$$\vec{T} + \vec{F}_n + \vec{F}_g = 0$$

Choose a coordinate system in which the $+x$ direction is in the direction of $\vec{T}$ and the $+y$ direction is in the direction of $\vec{F}_n$. Apply Newton's second law to the block to obtain expressions for $\vec{T}$ and $\vec{F}_n$.



(a) Apply $\sum F_x = 0$ to the box:

$$T - F_g \sin\theta = 0$$

or, because $F_g = mg$,

$$T - mg\sin\theta = 0 \Rightarrow T = mg\sin\theta \quad (1)$$

Substitute numerical values and evaluate T:

$$T = (50\,\text{kg})(9.81\,\text{m/s}^2)\sin 60° = \boxed{0.42\,\text{kN}}$$

Apply $\sum F_y = 0$ to the box:

$$F_n - F_g \cos\theta = 0$$

or, because $F_g = mg$,

$$F_n - mg\cos\theta = 0 \Rightarrow F_n = mg\cos\theta$$

Substitute numerical values and evaluate F_n:

$$F_n = (50\,\text{kg})(9.81\,\text{m/s}^2)\cos 60° = \boxed{0.25\,\text{kN}}$$

(*b*) The tension as a function of θ and m is given by equation (1):

$$T = \boxed{mg\sin\theta}$$

For $\theta = 90°$:

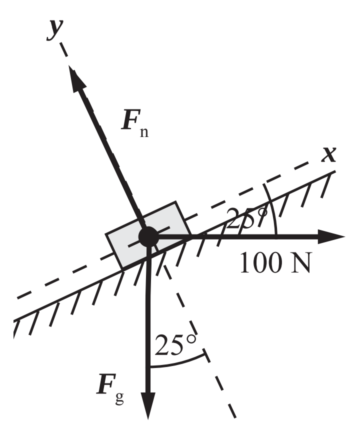
$T_{90°} = mg\sin 90° = \boxed{mg}$ … a result we know to be correct.

For $\theta = 0°$:

$T_{0°} = mg\sin 0° = \boxed{0}$ … a result we know to be correct.

60 •• A horizontal force of 100 N pushes a 12-kg block up a frictionless incline that makes an angle of 25º with the horizontal. (*a*) What is the normal force that the incline exerts on the block? (*b*) What is the acceleration of the block?

Picture the Problem Draw a free-body diagram for the box. Choose a coordinate system in which the positive x-axis is parallel to the inclined plane and the positive y-axis is in the direction of the normal force the incline exerts on the block. Apply Newton's second law of motion to find the normal force F_n that the incline exerts on the block and the acceleration a of the block.



(*a*) Apply $\sum F_y = ma_y$ to the block:

$$F_n - F_g\cos 25° - (100\,\text{N})\sin 25° = 0$$

or, because $F_g = mg$,

$$F_n - mg\cos 25° - (100\,\text{N})\sin 25° = 0$$

Solving for F_n yields:

$$F_n = mg\cos 25° + (100\,\text{N})\sin 25°$$

Substitute numerical values and evaluate F_n:

$$F_n = (12\,\text{kg})(9.81\,\text{m/s}^2)\cos 25° + (100\,\text{N})\sin 25° = \boxed{1.5\times10^2\ \text{N}}$$

(*b*) Apply $\sum F_x = ma_x$ to the block:

$$(100\,\text{N})\cos 25° - F_g \sin 25° = ma$$

or, because $F_g = mg$,

$$(100\,\text{N})\cos 25° - mg\sin 25° = ma$$

Solve for a to obtain:

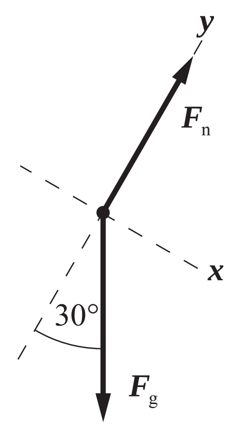
$$a = \frac{(100\,\text{N})\cos 25°}{m} - g\sin 25°$$

Substitute numerical values and evaluate a:

$$a = \frac{(100\,\text{N})\cos 25°}{12\,\text{kg}} - (9.81\,\text{m/s}^2)\sin 25° = \boxed{3.4\,\text{m/s}^2}$$

61 •• [SSM] A 65-kg student weighs himself by standing on a scale mounted on a skateboard that is rolling down an incline, as shown in Figure 4-47. Assume there is no friction so that the force exerted by the incline on the skateboard is normal to the incline. What is the reading on the scale if $\theta = 30°$?

Picture the Problem The scale reading (the boy's apparent weight) is the force the scale exerts on the boy. Draw a free-body diagram for the boy, choosing a coordinate system in which the positive x-axis is parallel to and down the inclined plane and the positive y-axis is in the direction of the normal force the incline exerts on the boy. Apply Newton's second law of motion in the y direction.



Apply $\sum F_y = ma_y$ to the boy to find F_n. Remember that there is no acceleration in the y direction:

$$F_n - F_g\cos 30° = 0$$

or, because $F_g = mg$,

$$F_n - mg\cos 30° = 0$$

Solving for F_n yields:

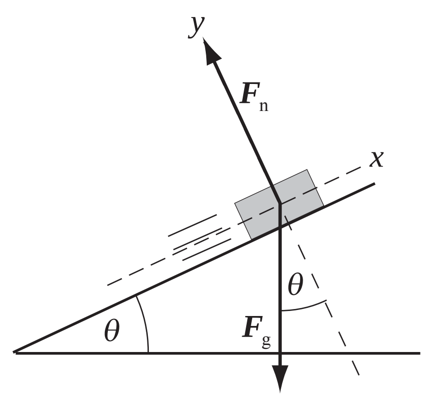
$$F_n = mg\cos 30°$$

Substitute numerical values and evaluate F_n:

$$F_n = (65\,\text{kg})(9.81\,\text{m/s}^2)\cos 30° = \boxed{0.55\,\text{kN}}$$

62 •• A block of mass m slides across a frictionless floor and then up a frictionless ramp (Figure 4-48). The angle of the ramp is θ and the speed of the block before it starts up the ramp is v_0. The block will slide up to some maximum height h above the floor before stopping. Show that h is independent of θ by deriving an expression for h in terms of v_0 and g.

Picture the Problem The free-body diagram for the block sliding up the incline is shown to the right. Applying Newton's second law to the forces acting in the x direction will lead us to an expression for a_x. Using this expression in a constant-acceleration equation will allow us to express h as a function of v_0 and g.



The height h is related to the distance Δx traveled up the incline:

$$h = \Delta x \sin\theta \qquad (1)$$

Using a constant-acceleration equation, relate the final speed of the block to its initial speed, acceleration, and distance traveled:

$$v_x^2 = v_{0x}^2 + 2a_x\Delta x$$

or, because $v_x = 0$,

$$0 = v_{0x}^2 + 2a_x\Delta x \Rightarrow \Delta x = \frac{-v_{0x}^2}{2a_x}$$

Substituting for Δx in equation (1) yields:

$$h = \frac{-v_{0x}^2}{2a_x}\sin\theta \qquad (2)$$

Apply $\sum F_x = ma_x$ to the block and solve for its acceleration:

$$-F_g \sin\theta = ma_x$$

Because $F_g = mg$:

$$-mg\sin\theta = ma_x \Rightarrow a_x = -g\sin\theta$$

Substitute for a_x in equation (2) and simplify to obtain:

$$h = \left(\frac{v_{0x}^2}{2g\sin\theta}\right)\sin\theta = \boxed{\frac{v_{0x}^2}{2g}}$$

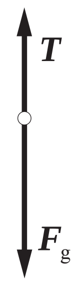
which is independent of the ramp's angle θ.

Free-Body Diagrams: Elevators

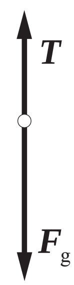
63 • **[SSM]** (*a*) Draw the free body diagram (with accurate relative force magnitudes) for an object that is hung by a rope from the ceiling of an elevator that is ascending but slowing. (*b*) Repeat Part (*a*) but for the situation in which the

elevator is descending and speeding up. (*c*) Can you tell the difference between the two diagrams? Explain why the diagrams do not tell anything about the object's velocity.

Picture the Problem
(*a*) The free body diagram for an object that is hung by a rope from the ceiling of an ascending elevator that is slowing down is shown to the right. Note that because $F_g > T$, the net force acting on the object is downward; as it must be if the object is slowing down as it is moving upward.



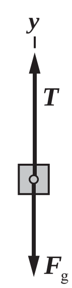
(*b*) The free body diagram for an object that is hung by a rope from the ceiling of an elevator that is descending and speeding up is shown to the right. Note that because $F_g > T$, the net force acting on the object is downward; as it must be if the object is speeding up as it descends.



(*c*) No, there is no difference. In both cases the acceleration is downward. You can only tell the direction of the acceleration, not the direction of the velocity.

64 • A 10.0-kg block is suspended from the ceiling of an elevator by a cord rated to withstand a tension of 150 N. Shortly after the elevator starts to ascend, the cord breaks. What was the minimum acceleration of the elevator when the cord broke?

Picture the Problem The free-body diagram shows the forces acting on the 10.0-kg block as the elevator accelerates upward. Apply Newton's second law to the block to find the minimum acceleration of the elevator required to break the cord.



Apply $\sum F_y = ma_y$ to the block:

$$T - F_g = ma_y$$

or, because $F_g = mg$,

$$T - mg = ma_y$$

Solve for a_y to determine the minimum breaking acceleration:

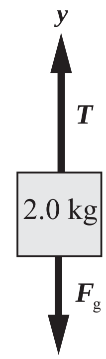
$$a_y = \frac{T - mg}{m} = \frac{T}{m} - g$$

Substitute numerical values and evaluate a_y:

$$a_y = \frac{150\,\text{N}}{10.0\,\text{kg}} - 9.81\,\text{m/s}^2 = \boxed{5.19\,\text{m/s}^2}$$

65 •• A 2.0-kg block hangs from a spring scale calibrated in newtons that is attached to the ceiling of an elevator (Figure 4-49). What does the scale read when (*a*) the elevator is ascending with a constant speed of 30 m/s, (*b*) the elevator is descending with a constant speed of 30 m/s, (*c*) the elevator is ascending at 20 m/s and gaining speed at a rate of 3.0 m/s^2? (*d*) Suppose that from $t = 0$ to $t = 5.0$ s, the elevator ascends at a constant speed of 10 m/s. Its speed is then steadily reduced to zero during the next 4.0 s, so that it is at rest at $t = 9.0$ s. Describe the reading of the scale during the interval $0 < t < 9.0$ s.

Picture the Problem The free-body diagram shows the forces acting on the 2-kg block as the elevator ascends at a constant velocity. Because the acceleration of the elevator is zero, the block is in equilibrium under the influence of $\vec{T}$ and $m\vec{g}$. Apply Newton's second law of motion to the block to determine the scale reading.



(*a*) Apply $\sum F_y = ma_y$ to the block to obtain:

$$T - F_g = ma_y$$

or, because $F_g = mg$,

$$T - mg = ma_y \qquad (1)$$

For motion with constant velocity, $a_y = 0$ and:

$$T - mg = 0 \Rightarrow T = mg$$

Substitute numerical values and evaluate T:

$$T = (2.0\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{20\,\text{N}}$$

(*b*) As in Part (*a*), for constant velocity, $a_y = 0$. Hence:

$$T - mg = 0$$

and

$$T = (2.0\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{20\,\text{N}}$$

(*c*) Solve equation (1) for T and simplify to obtain:

$$T = mg + ma_y = m(g + a_y) \qquad (2)$$

Because the elevator is ascending and its speed is increasing, we have $a_y = 3.0$ m/s^2. Substitute numerical values and evaluate T:

$$T = (2.0\,\text{kg})(9.81\,\text{m/s}^2 + 3.0\,\text{m/s}^2) = \boxed{26\,\text{N}}$$

(*d*) During the interval $0 < t < 5.0$ s, $a_y = 0$. Hence:

$$T_{0\to 5.0\,\text{s}} = \boxed{20\ \text{N}}$$

Using its definition, calculate a for $5.0\ \text{s} < t < 9.0$ s:

$$a = \frac{\Delta v}{\Delta t} = \frac{0 - 10\,\text{m/s}}{4.0\,\text{s}} = -2.5\,\text{m/s}^2$$

Substitute in equation (2) and evaluate T:

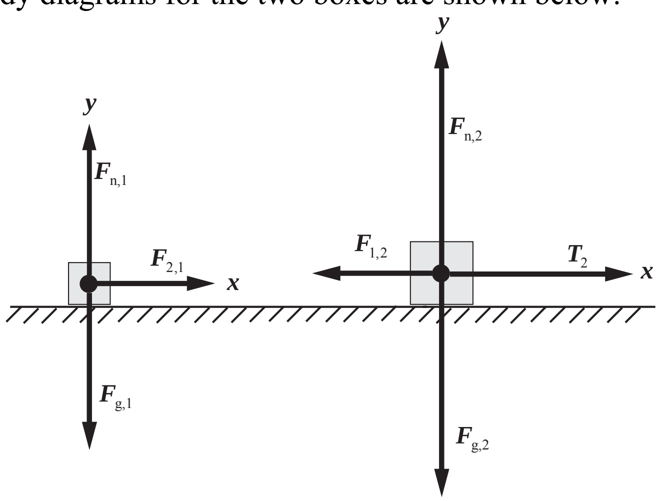
$$T_{5\text{s}\to 9\text{s}} = (2.0\,\text{kg})(9.81\,\text{m/s}^2 - 2.5\,\text{m/s}^2) = \boxed{15\,\text{N}}$$

Free-Body Diagrams: Several Objects and Newton's Third Law

66 •• Two boxes of mass m_1 and m_2 connected by a massless string are being pulled along a horizontal frictionless surface, as shown in Figure 4-50. (*a*) Draw the free body diagram of both boxes separately and show that $T_1/T_2 = m_1/(m_1 + m_2)$. (*b*) Is this result plausible? Explain. Does your answer make sense both in the limit that $m_2/m_1 >> 1$ and in the limit that $m_2/m_1 << 1$? Explain.

Picture the Problem Draw a free-body diagram for each box and apply Newton's second law. Solve the resulting simultaneous equations for the ratio of T_1 to T_2.

(*a*) The free-body diagrams for the two boxes are shown below:



Apply $\sum F_x = ma_x$ to the box on the left:

$F_{2,1} = m_1 a_{1x}$
or, because $F_{2,1} = T_1$,
$T_1 = m_1 a_{1x}$

Apply $\sum F_x = ma_x$ to the box on the right:

$T_2 - F_{1,2} = m_2 a_{2x}$
or, because $F_{1,2} = T_1$,
$T_2 - T_1 = m_2 a_{2x}$

Because the boxes have the same acceleration, we can divide the second equation by the first to obtain:

$$\frac{T_1}{T_2 - T_1} = \frac{m_1}{m_2} \Rightarrow \frac{T_1}{T_2} = \boxed{\frac{m_1}{m_1 + m_2}}$$

(*b*) Divide the numerator and denominator of the expression inside the parentheses by m_1 to obtain:

$$\frac{T_1}{T_2} = \frac{1}{1 + \frac{m_2}{m_1}}$$

For $m_2/m_1 << 1$:

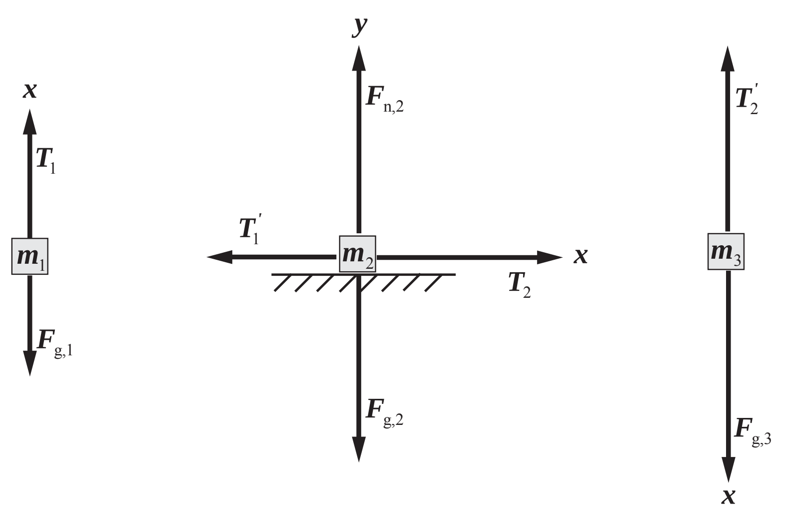
$$\frac{T_1}{T_2} \to \boxed{0}$$, as expected.

For $m_2/m_1 << 1$:

$$\frac{T_1}{T_2} \to \boxed{T_2}$$, as expected.

67 •• A box of mass $m_2 = 3.5$ kg rests on a frictionless horizontal shelf and is attached by strings to boxes of masses $m_1 = 1.5$ kg and $m_3 = 2.5$ kg as shown in Figure 4-51. Both pulleys are frictionless and massless. The system is released from rest. After it is released, find (*a*) the acceleration of each of the boxes and (*b*) the tension in each string.

Picture the Problem Call the common acceleration of the boxes *a*. Assume that box 1 moves upward, box 2 to the right, and box 3 downward and take this direction to be the positive *x* direction. Draw free-body diagrams for each of the boxes, apply Newton's second law of motion, and solve the resulting equations simultaneously. Note that $T_1 = T_1^{'}$ and $T_2 = T_2^{'}$.



(*a*) Apply $\sum F_x = ma_x$ to the box whose mass is m_1:

$$T_1 - F_{g,1} = m_1 a_x$$

or, because $F_{g,1} = m_1 g$,

$$T_1 - m_1 g = m_1 a_x \qquad (1)$$

Apply $\sum F_x = ma_x$ to the box whose mass is m_2:

$$T_2 - T_1' = m_2 a_x$$

or, because $T_1 = T_1'$,

$$T_2 - T_1 = m_2 a \qquad (2)$$

Noting that $T_2 = T_2'$, apply $\sum F_x = ma_x$ to the box whose mass is m_3:

$$F_{g,3} - T_2 = m_3 a_x$$

or, because $F_{g,3} = m_3 g$,

$$m_3 g - T_2 = m_3 a_x \qquad (3)$$

Add equations (1), (2), and (3) to obtain:

$$m_3 g - m_1 g = m_1 a_x + m_2 a_x + m_3 a_x$$

Solving for a_x gives:

$$a_x = \frac{(m_3 - m_1)g}{m_1 + m_2 + m_3}$$

Substitute numerical values and evaluate a_x:

$$a_x = \frac{(2.5\,\text{kg} - 1.5\,\text{kg})(9.81\,\text{m/s}^2)}{1.5\,\text{kg} + 3.5\,\text{kg} + 2.5\,\text{kg}} = 1.31\,\text{m/s}^2 = \boxed{1.3\,\text{m/s}^2}$$

(*b*) From equation (1) we have:

$$T_1 = m_1 a_x + m_1 g = m_1(a_x + g)$$

Substitute numerical values and evaluate T_1:

$$T_1 = (1.5\,\text{kg})(1.31\,\text{m/s}^2 + 9.81\,\text{m/s}^2) = \boxed{17\,\text{N}}$$

From equation (3) we have:

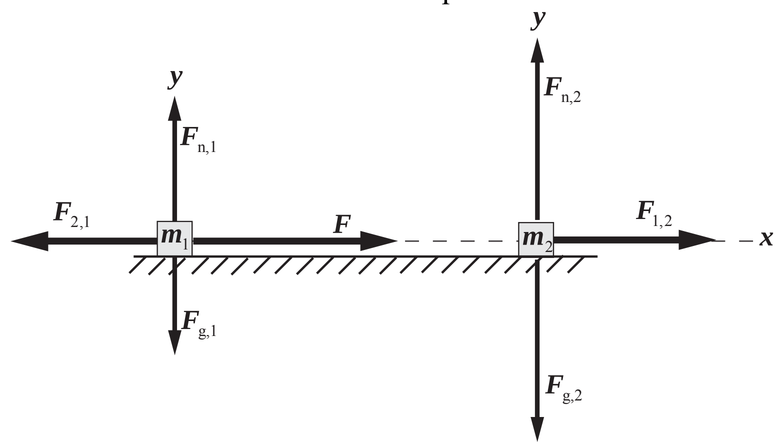
$$T_2 = m_3 g - m_3 a_x = m_3(g - a_x)$$

Substitute numerical values and evaluate T_2:

$$T_2 = (2.5\,\text{kg})(9.81\,\text{m/s}^2 - 1.31\,\text{m/s}^2) = \boxed{21\,\text{N}}$$

68 •• Two blocks are in contact on a frictionless horizontal surface. The blocks are accelerated by a single horizontal force $\vec{F}$ applied to one of them (Figure 4-52). Find the acceleration and the contact force of block 1 on block 2 (*a*) in terms of F, m_1, and m_2, and (*b*) for the specific values F = 3.2 N, m_1 = 2.0 kg, and m_2 = 6.0 kg.

Picture the Problem Choose a coordinate system in which the $+x$ direction is to the right and the $+y$ direction is upward. Let $\vec{F}_{2,1}$ be the contact force exerted by the block whose mass is m_2 on the block whose mass is m_1 and $\vec{F}_{1,2}$ be the force exerted by the block whose mass is m_1 on the block whose mass is m_2. These forces are equal and opposite so $\vec{F}_{2,1} = -\vec{F}_{1,2}$. The free- body diagrams for the blocks are shown below. Apply Newton's second law to each block separately and use the fact that their accelerations are equal.



(a) Apply $\sum F_x = ma_x$ to the block whose mass is m_1:

$F - F_{2,1} = m_1 a_{1x}$

or, because the blocks have a common acceleration a_x,

$$F - F_{2,1} = m_1 a_x \qquad (1)$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$$F_{1,2} = m_2 a_x \qquad (2)$$

Adding equations (1) and (2) yields:

$$F = m_1 a_x + m_2 a_x = (m_1 + m_2)a_x$$

Solve for a_x to obtain:

$$a_x = \boxed{\frac{F}{m_1 + m_2}}$$

Substitute for a in equation (1) to obtain:

$$F_{1,2} = m_2\left(\frac{F}{m_1 + m_2}\right) = \boxed{\frac{Fm_2}{m_1 + m_2}}$$

(b) Substitute numerical values in the equations derived in Part (a) and evaluate a_x and $F_{1,2}$:

$$a_x = \frac{3.2\,\text{N}}{2.0\,\text{kg} + 6.0\,\text{kg}} = \boxed{0.40\,\text{m/s}^2}$$

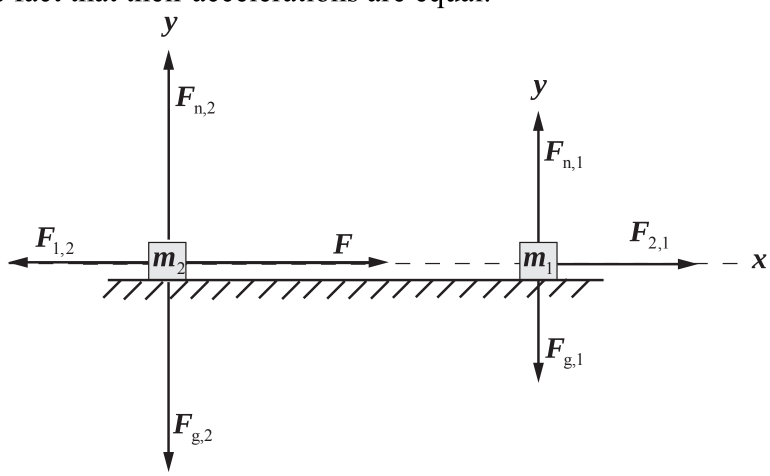
and

$$F_{1,2} = \frac{(3.2\,\text{N})(6.0\,\text{kg})}{2.0\,\text{kg} + 6.0\,\text{kg}} = \boxed{2.4\,\text{N}}$$

Remarks: Note that our results for the acceleration are the same as if the force $\boldsymbol{F}$ had acted on a single object whose mass is equal to the sum of the masses of the two blocks. In fact, because the two blocks have the same acceleration, we can consider them to be a single system with mass $m_1 + m_2$.

69 •• Repeat Problem 68, but with the two blocks interchanged. Are your answers the same as in Problem 68? Explain.

Picture the Problem Choose a coordinate system in which the +*x* direction is to the right and the +*y* direction is upward. Let $\vec{F}_{2,1}$ be the contact force exerted by the block whose mass is m_2 on the block whose mass is m_1 and $\vec{F}_{1,2}$ be the force exerted by the block whose mass is m_1 on the block whose mass is m_2. These forces are equal and opposite so $\vec{F}_{2,1} = -\vec{F}_{1,2}$. The free- body diagrams for the blocks are shown. We can apply Newton's second law to each block separately and use the fact that their accelerations are equal.



(*a*) Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$F - F_{1,2} = m_2 a_{2x}$

or, because the blocks have a common acceleration a_x,

$$F - F_{1,2} = m_2 a_x \quad (1)$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_1:

$$F_{2,1} = m_1 a_x \quad (2)$$

Add these equations to eliminate $F_{2,1}$ and $F_{1,2}$:

$F - F_{1,2} + F_{2,1} = m_2 a_x + m_1 a_x$

or, because $F_{1,2} = F_{2,1}$,

$F = (m_2 + m_1)a_x$

Solve for a_x to obtain:

$$a_x = \boxed{\frac{F}{m_1 + m_2}}$$

Substituting for a into equation (2) yields:

$$F_{2,1} = m_1\left(\frac{F}{m_1 + m_2}\right) = \boxed{\frac{Fm_1}{m_1 + m_2}}$$

(b) Substitute numerical values in the equations derived in Part (a) and evaluate a_x and $F_{2,1}$:

$$a = \frac{3.2\,\text{N}}{2.0\,\text{kg} + 6.0\,\text{kg}} = \boxed{0.40\,\text{m/s}^2}$$

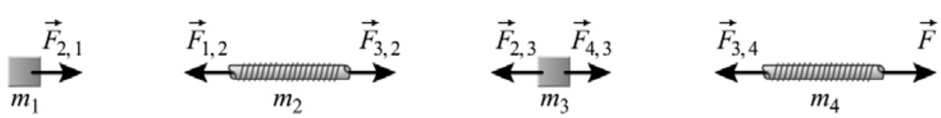
and

$$F_{2,1} = \frac{(3.2\,\text{N})(2.0\,\text{kg})}{2.0\,\text{kg} + 6.0\,\text{kg}} = \boxed{0.80\,\text{N}}$$

Remarks: Note that our results for the acceleration are the same as if the force *F* had acted on a single object whose mass is equal to the sum of the masses of the two blocks. In fact, because the two blocks have the same acceleration, we can consider them to be a single system with mass $m_1 + m_2$.

70 •• Two 100-kg boxes are dragged along a horizontal frictionless surface at a constant acceleration of 1.00 m/s^2, as shown in Figure 4-53. Each rope has a mass of 1.00 kg. Find the force F and the tension in the ropes at points A, B, and C.

Picture the Problem The free-body diagrams for the boxes and the ropes are below. Because the vertical forces have no bearing on the problem they have not been included. Let the numeral 1 denote the 100-kg box to the left, the numeral 2 the rope connecting the boxes, the numeral 3 the box to the right and the numeral 4 the rope to which the force $\vec{F}$ is applied. $\vec{F}_{3,4}$ is the tension force exerted by the box whose mass is m_3 on the rope whose mass is m_4, $\vec{F}_{4,3}$ is the tension force exerted by the rope whose mass is m_4 on the box whose mass is m_3, $\vec{F}_{2,3}$ is the tension force exerted by the rope whose mass is m_2 on the box whose mass is m_3, $\vec{F}_{3,2}$ is the tension force exerted by the box whose mass is m_3 on the rope whose mass is m_2, $\vec{F}_{1,2}$ is the tension force exerted by the box whose mass is m_1 on the rope whose mass is m_2, and $\vec{F}_{2,1}$ is the tension force exerted by the rope whose mass is m_2 on the box whose mass is m_1. The equal and opposite pairs of forces are $\vec{F}_{2,1} = -\vec{F}_{1,2}$, $\vec{F}_{3,2} = -\vec{F}_{2,3}$, and $\vec{F}_{4,3} = -\vec{F}_{3,4}$. We can apply Newton's second law to each box and rope separately and use the fact that their accelerations are equal.



Apply $\sum \vec{F} = m\vec{a}$ to the box whose mass is m_1:

$$F_{2,1} = m_1 a_1 = m_1 a \qquad (1)$$

Apply $\sum\vec{F} = m\vec{a}$ to the rope whose mass is m_2:

$$F_{3,2} - F_{1,2} = m_2 a_2 = m_2 a \qquad (2)$$

Apply $\sum\vec{F} = m\vec{a}$ to the box whose mass is m_3:

$$F_{4,3} - F_{2,3} = m_3 a_3 = m_3 a \qquad (3)$$

Apply $\sum\vec{F} = m\vec{a}$ to the rope whose mass is m_4:

$$F - F_{3,4} = m_4 a_4 = m_4 a$$

Add these equations to eliminate $F_{2,1}$, $F_{1,2}$, $F_{3,2}$, $F_{2,3}$, $F_{4,3}$, and $F_{3,4}$ and solve for F:

$$F = (m_1 + m_2 + m_3 + m_4)a$$

Substitute numerical values and evaluate F:

$$F = (202\,\text{kg})(1.00\,\text{m/s}^2) = \boxed{202\,\text{N}}$$

Use equation (1) to find the tension at point A:

$$F_{2,1} = (100\,\text{kg})(1.00\,\text{m/s}^2) = \boxed{100\,\text{N}}$$

Use equation (2) to express the tension at point B:

$$F_{3,2} = F_{1,2} + m_2 a$$

Substitute numerical values and evaluate $F_{3,2}$:

$$F_{3,2} = 100\,\text{N} + (1.00\,\text{kg})(1.00\,\text{m/s}^2) = \boxed{101\,\text{N}}$$

Use equation (3) to express the tension at point C:

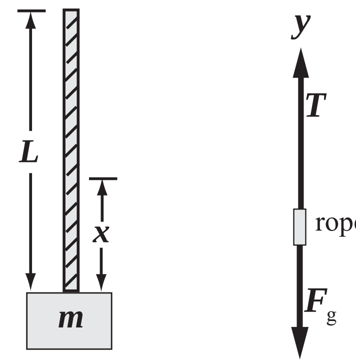
$$F_{4,3} = F_{2,3} + m_3 a$$

Substitute numerical values and evaluate $F_{4,3}$:

$$F_{4,3} = 101\,\text{N} + (100\,\text{kg})(1.00\,\text{m/s}^2) = \boxed{201\,\text{N}}$$

71 •• [SSM] A block of mass m is being lifted vertically by a rope of mass M and length L. The rope is being pulled upward by a force applied at its top end, and the rope and block are accelerating upward with an acceleration of magnitude a. The distribution of mass in the rope is uniform. Show that the tension in the rope at a distance x (where $x < L$) above the block is $(a + g)[m + (x/L)M]$.

Picture the Problem Because the distribution of mass in the rope is uniform, we can express the mass m' of a length x of the rope in terms of the total mass of the rope M and its length L. We can then express the total mass that the rope must support at a distance x above the block and use Newton's second law to find the tension as a function of x.



Set up a proportion expressing the mass m' of a length x of the rope as a function of M and L and solve for m':

$$\frac{m'}{x} = \frac{M}{L} \Rightarrow m' = \frac{M}{L}x$$

Express the total mass that the rope must support at a distance x above the block:

$$m + m' = m + \frac{M}{L}x$$

Apply $\sum F_y = ma_y$ to the block and a length x of the rope:

$$T - F_g = T - (m + m')g = (m + m')a_y$$

Substituting for $m + m'$ yields:

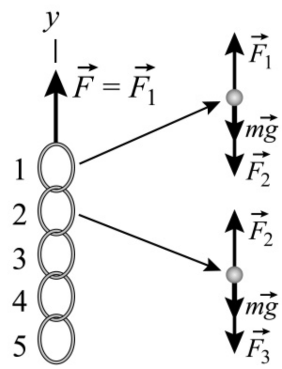
$$T - \left(m + \frac{M}{L}x\right)g = \left(m + \frac{M}{L}x\right)a_y$$

Solve for T and simplify to obtain:

$$T = \boxed{(a_y + g)\left(m + \frac{M}{L}x\right)}$$

72 •• A chain consists of 5 links, each having a mass of 0.10 kg. The chain is being pulled upward by a force applied by your hand to its top link, giving the chain an upward acceleration of 2.5 m/s^2. Find (*a*) the force magnitude F exerted on the top link by your hand; (*b*) the net force on each link; and (*c*) the magnitude of the force each link exerts on the link below it.

Picture the Problem Choose a coordinate system with the +y direction upward and denote the top link with the numeral 1, the second with the numeral 2, etc. The free-body diagrams show the forces acting on links 1 and 2. We can apply Newton's second law to each link to obtain a system of simultaneous equations that we can solve for the force each link exerts on the link below it. Note that the net force on each link is the product of its mass and acceleration.



(*a*) Apply $\sum F_y = ma_y$ to the top link and solve for *F*:

$$F - 5mg = 5ma$$

and

$$F = 5m(g + a)$$

Substitute numerical values and evaluate *F*:

$$F = 5(0.10\,\text{kg})(9.81\,\text{m/s}^2 + 2.5\,\text{m/s}^2) = \boxed{6.2\,\text{N}}$$

(*b*) Apply $\sum F_y = ma_y$ to a single link:

$$F_{1\,\text{link}} = m_{1\,\text{link}}a = (0.10\,\text{kg})(2.5\,\text{m/s}^2) = \boxed{0.25\,\text{N}}$$

(*c*) Apply $\sum F_y = ma_y$ to the 1st through 5th links to obtain:

$$F - F_2 - mg = ma\,, \quad (1)$$
$$F_2 - F_3 - mg = ma\,, \quad (2)$$
$$F_3 - F_4 - mg = ma\,, \quad (3)$$
$$F_4 - F_5 - mg = ma\,, \text{ and} \quad (4)$$
$$F_5 - mg = ma \quad (5)$$

Add equations (2) through (5) to obtain:

$$F_2 - 4mg = 4ma$$

Solve for F_2 to obtain:

$$F_2 = 4mg + 4ma = 4m(a + g)$$

Substitute numerical values and evaluate F_2:

$$F_2 = 4(0.10\,\text{kg})(9.81\,\text{m/s}^2 + 2.5\,\text{m/s}^2) = \boxed{4.9\,\text{N}}$$

Substitute for F_2 to find F_3, and then substitute for F_3 to find F_4:

$$F_3 = \boxed{3.7\,\text{N}} \text{ and } F_4 = \boxed{2.5\,\text{N}}$$

Solve equation (5) for F_5:

$$F_5 = m(g + a)$$

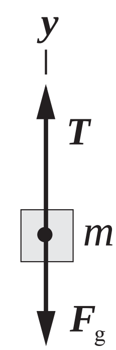
Substitute numerical values and evaluate F_5:

$$F_5 = (0.10\,\text{kg})(9.81\,\text{m/s}^2 + 2.5\,\text{m/s}^2) = \boxed{1.2\,\text{N}}$$

73 •• [SSM] A 40.0-kg object is supported by a vertical rope. The rope, and thus the object, is then accelerated from rest upward so that it attains a speed of 3.50 m’s in 0.700 s. (*a*) Draw the object’s free body diagram with the relative lengths of the vectors showing the relative magnitudes of the forces. (*b*) Use the free-body diagram and Newton’s laws to determine the tension in the rope.

Picture the Problem A *net* force is required to accelerate the object. In this problem the net force is the difference between $\vec{T}$ and $\vec{F}_g\,(= m\vec{g})$.

(*a*) The free-body diagram of the object is shown to the right. A coordinate system has been chosen in which the upward direction is positive. The magnitude of $\vec{T}$ is approximately 1.5 times the length of $\vec{F}_g$.



(*b*) Apply $\sum F = ma_y$ to the object to obtain:

$$T - mg = ma_y$$

Solving for T yields:

$$T = ma + mg = m(a_y + g)$$

Using its definition, substitute for a_y to obtain:

$$T = m\left(\frac{\Delta v_y}{\Delta t} + g\right)$$

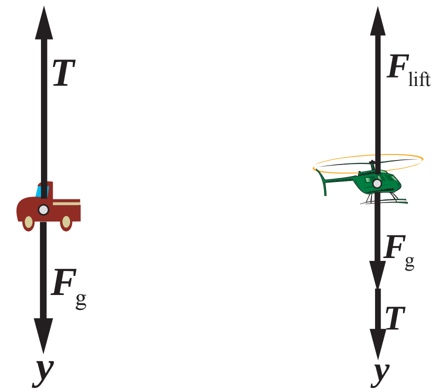
Substitute numerical values and evaluate T:

$$T = (40.0\,\text{kg})\left(\frac{3.50\,\text{m/s}}{0.700\,\text{s}} + 9.81\,\text{m/s}^2\right) = \boxed{592\,\text{N}}$$

74 •• A 15 000-kg helicopter is lowering a 4000-kg truck by a cable of fixed length. The truck, helicopter, and cable are descending at 15.0 m/s and must be slowed to 5.00 m/s in the next 50.0 m of descent to prevent damaging the truck. Assume a constant rate of slowing. (*a*) Draw the free-body diagram of the truck. (*b*) Determine the tension in the cable. (*c*) Determine the lift force of the helicopter blades.

Picture the Problem A net force in the upward direction is required to slow the truck's descent. This net force is the difference between $\vec{T}$ and $\vec{F}_g$. We can use Newton's second law and a constant-acceleration equation to find the tension in the cable that supports the truck.

(*a*) Free-body diagrams showing the forces acting on the truck and on the helicopter are shown to the right. A coordinate system in which the downward direction is positive has been chosen. Note that, because it is hovering, the helicopter is in equilibrium under the influence of the forces $\vec{F}_{\text{lift}}$, $\vec{F}_g$, and $\vec{T}$.



(*b*) Apply $\sum F_y = ma_y$ to the truck to obtain:

$$F_g - T = m_t a_y$$

or, because $F_g = m_t g$,

$$m_t g - T = m_t a_y$$

Solve for the tension in the lower portion of the cable:

$$T = m_t g - m_t a_y = m_t(g - a_y) \quad (1)$$

Use a constant-acceleration equation to relate the truck's initial and final speeds to its displacement and acceleration:

$$v_y^2 = v_{0y}^2 + 2a_y \Delta y \Rightarrow a_y = \frac{v_y^2 - v_{0y}^2}{2\Delta y}$$

Substitute numerical values and evaluate a_y:

$$a_y = \frac{(5.00\text{ m/s})^2 - (15.0\text{ m/s})^2}{2(50.0\text{ m})} = -2.000\text{ m/s}^2$$

Substitute numerical values in equation (1) and evaluate T:

$$T = (4000\text{ kg})(9.81\text{ m/s}^2 + 2.000\text{ m/s}^2) = 47.24\text{ kN} = \boxed{47.2\text{ kN}}$$

(*c*) Apply $\sum F_y = ma_y$ to the helicopter to obtain:

$$m_h g + T - F_{\text{lift}} = m_h a_y$$

Solving for F_{lift} yields:

$$F_{\text{lift}} = m_h g + T - m_h a_y = m_h(g - a_y) + T$$

Substitute for T from Part (a):

$$F_{\text{lift}} = m_{\text{h}}(g - a_y) + m_{\text{t}}(g - a_y) = (m_{\text{t}} + m_{\text{h}})(g - a_y)$$

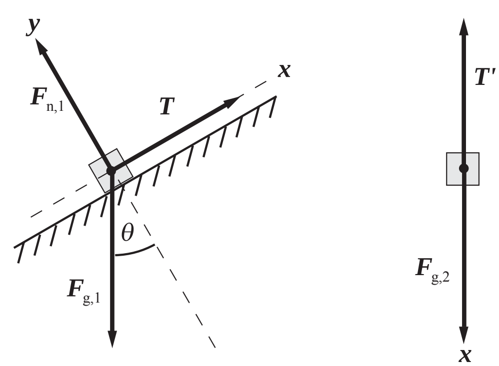
Substitute numerical values and evaluate F_{lift}:

$$F_{\text{lift}} = (4000\text{ kg} + 15000\text{ kg})(9.81\text{ m/s}^2 + 2.00\text{ m/s}^2) = \boxed{224\text{ kN}}$$

75 •• Two objects are connected by a massless string, as shown in Figure 4-54. The incline and the massless pulley are frictionless. Find the acceleration of the objects and the tension in the string for (a) in terms of θ, m_1 and m_2, and (b) $\theta = 30°$ and $m_1 = m_2 = 5.0$ kg.

Picture the Problem Because the string does not stretch or become slack, the two objects must have the same speed and therefore the magnitude of the acceleration is the same for each object. Choose a coordinate system in which up the incline is the $+x$ direction for the object of mass m_1 and downward is the $+x$ direction for the object of mass m_2. This idealized pulley acts like a piece of polished pipe; i.e., its only function is to change the direction the tension in the massless string acts. Draw a free-body diagram for each of the two objects, apply Newton's second law to both objects, and solve the resulting equations simultaneously.

(a) The free-body diagrams for the two objects are shown to the right:



Apply $\sum F_x = ma_x$ to the object whose mass is m_1:

$$T - F_{g,1}\sin\theta = m_1 a_{1x}$$

or, because $F_{g,1} = m_1 g$ and the two objects have a common acceleration a_x,

$$T - m_1 g\sin\theta = m_1 a_x \qquad (1)$$

Apply $\sum F_x = ma_x$ to the object whose mass is m_2 to obtain:

$$m_2 g - T = m_2 a_x \qquad (2)$$

Adding equations (1) and (2) yields:

$$m_2 g - m_1 g\sin\theta = m_1 a_x + m_2 a_x$$

Solve for a_x to obtain:

$$a_x = \boxed{\frac{g(m_2 - m_1\sin\theta)}{m_1 + m_2}} \qquad (3)$$

Substitute for a_x in either of the equations containing the tension and solve for T to obtain:

$$T = \boxed{\frac{gm_1m_2(1+\sin\theta)}{m_1+m_2}} \qquad (4)$$

(*b*) Substitute numerical values in equation (3) and evaluate a_x:

$$a_x = \frac{(9.81\text{ m/s}^2)(5.0\text{ kg} - (5.0\text{ kg})\sin 30°)}{5.0\text{ kg} + 5.0\text{ kg}} = \boxed{2.5\text{ m/s}^2}$$

Substitute numerical values in equation (4) and evaluate T:

$$T = \frac{(9.81\text{ m/s}^2)(5.0\text{ kg})^2(1+\sin 30°)}{5.0\text{ kg} + 5.0\text{ kg}} = \boxed{37\text{ N}}$$

76 •• During a stage production of *Peter Pan*, the 50-kg actress playing Peter has to fly in vertically (descend). To be in time with the music, she must be lowered, starting from rest, a distance of 3.2 m in 2.2 s at constant acceleration. Backstage, a smooth surface sloped at 50º supports a counterweight of mass m, as shown in Figure 4-55. Show the calculations that the stage manager must perform to find (*a*) the mass of the counterweight that must be used and (*b*) the tension in the wire.

Picture the Problem The magnitudes of the accelerations of Peter and the counterweight are the same. Choose a coordinate system in which up the incline is the +x direction for the counterweight and downward is the +x direction for Peter. The pulley changes the direction the tension in the rope acts. Let Peter's mass be m_P. Ignoring the mass of the rope, draw free-body diagrams for the counterweight and Peter, apply Newton's second law to each of them, and solve the resulting equations simultaneously.

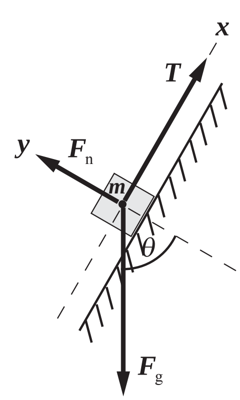
(*a*) Using a constant-acceleration equation, relate Peter's displacement to her acceleration and descent time:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$

or, because $v_{0x} = 0$,

$$\Delta x = \tfrac{1}{2}a_x(\Delta t)^2 \Rightarrow a_x = \frac{2\Delta x}{(\Delta t)^2}$$

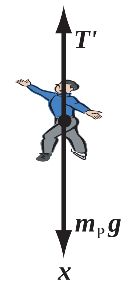
The free-body diagram for the counterweight is shown to the right:



Apply $\sum F_x = ma_x$ to the counterweight:

$$T - mg\sin 50° = ma_x$$

The free-body diagram for Peter is shown to the right:



Noting that $T' = T$, apply $\sum F_x = ma_x$ to Peter:

$$m_P g - T = m_P a_x$$

Adding the two equations and solving for m yields:

$$m = \frac{m_P(g - a_x)}{a_x + g\sin 50°}$$

Substituting for a_x yields:

$$m = \frac{m_P\left(g - \dfrac{2\Delta x}{(\Delta t)^2}\right)}{\dfrac{2\Delta x}{(\Delta t)^2} + g\sin 50°}$$

Substitute numerical values and evaluate m:

$$m = \frac{(50\text{ kg})\left(9.81\text{ m/s}^2 - \dfrac{2(3.2\text{ m})}{(2.2\text{ s})^2}\right)}{\dfrac{2(3.2\text{ m})}{(2.2\text{ s})^2} + 9.81\text{ m/s}^2\sin 50°}$$
$$= 48.0\text{ kg} = \boxed{48\text{ kg}}$$

(*b*) Substitute for m in the force equation for the counterweight and solve for T to obtain:

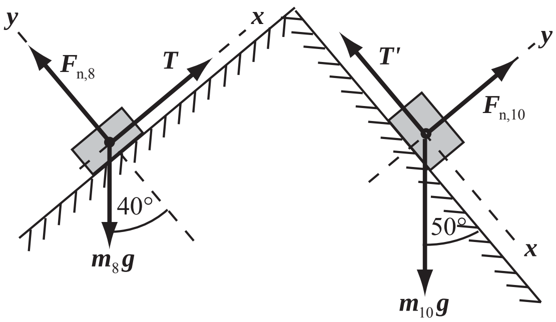
$$T = m(a_x + g\sin 50°)$$

Substitute numerical values and evaluate T:

$$T = (48.0\text{kg})\left[1.32\text{ m/s}^2 + (9.81\text{ m/s}^2)\sin 50°\right] = \boxed{0.42\text{ kN}}$$

77 •• An 8.0-kg block and a 10-kg block, connected by a rope that passes over a frictionless peg, slide on frictionless inclines (Figure 4-56). (*a*) Find the acceleration of the blocks and the tension in the rope. (*b*) The two blocks are replaced by two others of masses m_1 and m_2 such that there is no acceleration. Find whatever information you can about the masses of these two new blocks.

Picture the Problem The magnitude of the accelerations of the two blocks are the same. Choose a coordinate system in which up the incline is the $+x$ direction for the 8.0-kg object and downward is the $+x$ direction for the 10-kg object. The peg changes the direction the tension in the rope acts. Draw free-body diagrams for each object, apply Newton's second law of motion to both of them, and solve the resulting equations simultaneously.



(*a*) Apply $\sum F_x = ma_x$ to the 8.0-kg block:

$$T - m_8 g\sin 40° = m_8 a_x \qquad (1)$$

Noting that $T = T'$, apply $\sum F_x = ma_x$ to the 10-kg block:

$$m_{10} g\sin 50° - T = m_{10} a_x \qquad (2)$$

Add equations (1) and (2) to obtain:

$$m_{10} g\sin 50° - m_8 g\sin 40° = (m_{10} + m_8)a_x$$

Solving for a_x yields:

$$a_x = \frac{g(m_{10}\sin 50° - m_8\sin 40°)}{m_8 + m_{10}}$$

Substitute numerical values and evaluate a_x:

$$a_x = \frac{(9.81\text{ m/s}^2)((10\text{ kg})\sin 50° - (8.0\text{ kg})\sin 40°)}{8.0\text{ kg} + 10\text{ kg}} = 1.37\text{ m/s}^2 = \boxed{1.4\text{ m/s}^2}$$

Solving the first of the two force equations for T yields:

$$T = m_8(g\sin 40° + a_x)$$

Substitute numerical values and evaluate T:

$$T = (8.0\text{ kg})\left[(9.81\text{ m/s}^2)\sin 40° + 1.37\text{ m/s}^2\right] = \boxed{61\text{ N}}$$

(*b*) Because the system is in equilibrium, $a_x = 0$, and equations (1) and (2) become:

$$T - m_1 g\sin 40° = 0 \qquad (3)$$

and

$$m_2 g\sin 50° - T = 0 \qquad (4)$$

Adding equations (3) and (4) yields:

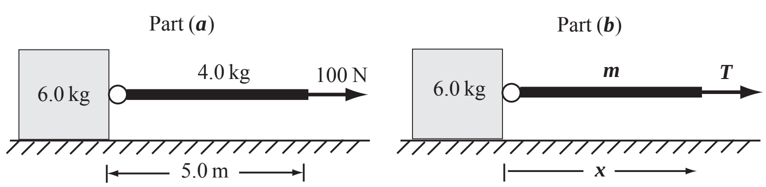
$$m_2 g\sin 50° - m_1 g\sin 40° = 0$$

Solve for and evaluate the ratio m_1/m_2 to obtain:

$$\frac{m_1}{m_2} = \frac{\sin 50°}{\sin 40°} = \boxed{1.19}$$

78 •• A heavy rope of length 5.0 m and mass 4.0 kg lies on a frictionless horizontal table. One end is attached to a 6.0-kg block. The other end of the rope is pulled by a constant horizontal 100-N force. (*a*) What is the acceleration of the system? (*b*) Give the tension in the rope as a function of position along the rope.

Picture the Problem The pictorial representations shown below summarize the information given in this problem. While the mass of the rope is distributed over its length, the rope and the 6.0-kg block have a common acceleration. Choose a coordinate system in which the direction of the 100-N force is the +*x* direction. Because the surface is horizontal and frictionless, the only force that influences our solution is the 100-N force.



(*a*) Apply $\sum F_x = ma_x$ to the system shown for Part (*a*):

$$100\text{ N} = (m_1 + m_2)a_x$$

Solve for a_x to obtain:

$$a_x = \frac{100\text{ N}}{m_1 + m_2}$$

Substitute numerical values and evaluate a_x:

$$a_x = \frac{100\text{ N}}{4.0\text{ kg} + 6.0\text{ kg}} = \boxed{10\text{ m/s}^2}$$

(*b*) Let *m* represent the mass of a length *x* of the rope. Assuming that the mass of the rope is uniformly distributed along its length:

$$\frac{m}{x} = \frac{m_2}{L_{\text{rope}}} = \frac{4.0\text{kg}}{5.0\text{m}} \Rightarrow m = \left(\frac{4.0\text{kg}}{5.0\text{m}}\right)x$$

Apply $\sum F_x = ma_x$ to the block in Part (*b*) to obtain:

$$T = (m_1 + m)a_x$$

Substituting for *m* yields:

$$T = \left(m_1 + \left(\frac{4.0\text{kg}}{5.0\text{m}}\right)x\right)a_x$$

Substitute numerical values and evaluate T:

$$T = \left[6.0\,\text{kg} + \left(\frac{4.0\,\text{kg}}{5.0\,\text{m}}\right)x\right]\left(10\,\text{m/s}^2\right)$$
$$= \boxed{60\,\text{N} + (8.0\,\text{N/m})x}$$

79 •• **[SSM]** A 60-kg housepainter stands on a 15-kg aluminum platform. The platform is attached to a rope that passes through an overhead pulley, which allows the painter to raise herself and the platform (Figure 4-57). (*a*) To accelerate herself and the platform at a rate of 0.80 m/s^2, with what force F must she pull down on the rope? (*b*) When her speed reaches 1.0 m/s, she pulls in such a way that she and the platform go up at a constant speed. What force is she exerting on the rope now? (Ignore the mass of the rope.)

Picture the Problem Choose a coordinate system in which the upward direction is the positive y direction. Note that $\vec{F}$ is the force exerted by the painter on the rope and that $\vec{T}$ is the resulting tension in the rope. Hence the net upward force on the painter-plus-platform is $2\vec{T}$.

(*a*) Letting $m_{\text{tot}} = m_{\text{frame}} + m_{\text{painter}}$, apply $\sum F_y = ma_y$ to the frame-plus-painter:

$$2T - m_{\text{tot}}g = m_{\text{tot}}a_y$$

Solving for T gives:

$$T = \frac{m_{\text{tot}}\left(a_y + g\right)}{2}$$

Substitute numerical values and evaluate T:

$$T = \frac{(75\,\text{kg})\left(0.80\,\text{m/s}^2 + 9.81\,\text{m/s}^2\right)}{2}$$
$$= 398\,\text{N}$$

Because $F = T$:

$$F = 398\text{ N} = \boxed{0.40\,\text{kN}}$$

(*b*) Apply $\sum F_y = 0$ to obtain:

$$2T - m_{\text{tot}}g = 0 \Rightarrow T = \tfrac{1}{2}m_{\text{tot}}g$$

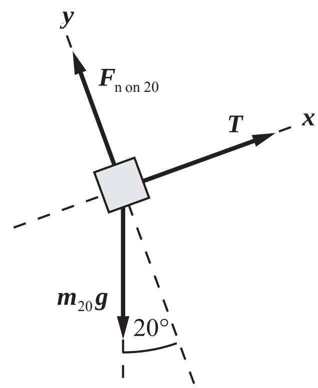
Substitute numerical values and evaluate T:

$$T = \tfrac{1}{2}(75\,\text{kg})\left(9.81\,\text{m/s}^2\right) = \boxed{0.37\,\text{kN}}$$

80 ••• Figure 4-58 shows a 20-kg block sliding on a 10-kg block. All surfaces are frictionless and the pulley is massless and frictionless. Find the acceleration of each block and the tension in the string that connects the blocks.

Picture the Problem Choose a coordinate system in which up the incline is the $+x$ direction and draw free-body diagrams for each block. Noting that $\vec{a}_{20} = -\vec{a}_{10}$, apply Newton's second law to each block and solve the resulting equations simultaneously.

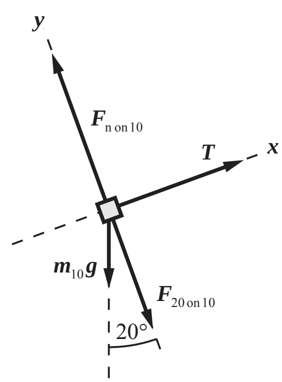
Draw a free-body diagram for the 20-kg block:



Apply $\sum F_x = ma_x$ to the block to obtain:

$$T - m_{20}g\sin 20° = m_{20}a_{20,x} \qquad (1)$$

Draw a free-body diagram for the 10-kg block. Because all the surfaces, including the surfaces between the blocks, are frictionless, the force the 20-kg block exerts on the 10-kg block must be normal to their surfaces as shown to the right.



Apply $\sum F_x = ma_x$ to the block to obtain:

$$T - m_{10}g\sin 20° = m_{10}a_{10,x} \qquad (2)$$

Because the blocks are connected by a taut string:

$$a_{20,x} = -a_{10,x}$$

Substituting for $a_{20,x}$ in equation (1) yields:

$$T - m_{20}g\sin 20° = -m_{20}a_{10,x} \qquad (3)$$

Eliminate T between equations (2) and (3) to obtain:

$$a_{10,x} = \left(\frac{m_{20} - m_{10}}{m_{20} + m_{10}}\right)g\sin 20°$$

Substitute numerical values and evaluate $a_{10,x}$:

$$a_{10,x} = \left(\frac{20\text{ kg} - 10\text{ kg}}{20\text{ kg} + 10\text{ kg}}\right)\left(9.81\text{ m/s}^2\right)\sin 20° = \boxed{1.1\text{ m/s}^2}$$

Because $a_{20,x} = -a_{10,x}$:

$$a_{20,x} = \boxed{-1.1\text{ m/s}^2}$$

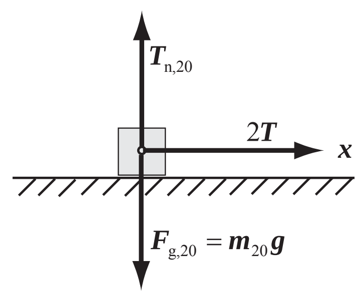
Substitute for either of the accelerations in the force equations and solve for T:

$$T = \boxed{45\text{ N}}$$

81 ••• A 20-kg block with a pulley attached slides along a frictionless ledge. It is connected by a massless string to a 5.0-kg block via the arrangement shown in Figure 4-59. Find (*a*) the acceleration of each block and (*b*) the tension in the connecting string.

Picture the Problem Choose a coordinate system in which the +*x* direction is to the right and draw free-body diagrams for each block. Because of the pulley, the string exerts a force of 2*T*. Apply Newton's second law of motion to both blocks and solve the resulting equations simultaneously.

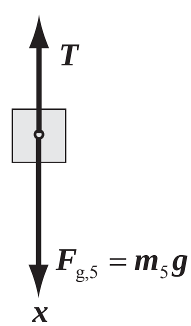
(*a*) Draw a free-body diagram for the 20-kg block:



Apply $\sum F_x = ma_x$ to the block to obtain:

$$2T = m_{20}a_{20,x}$$

Draw a free-body diagram for the 5.0-kg block:



Apply $\sum F_x = ma_x$ to the block to obtain:

$$m_5 g - T = m_5 a_{5,x}$$

Using a constant-acceleration equation, relate the displacement of the 5.0-kg block to its acceleration and the time during which it is accelerated:

$$\Delta x_5 = \tfrac{1}{2} a_{5,x} (\Delta t)^2$$

Using a constant-acceleration equation, relate the displacement of the 20-kg block to its acceleration and acceleration time:

$$\Delta x_{20} = \tfrac{1}{2} a_{20,x} (\Delta t)^2$$

Divide the first of these equations by the second to obtain:

$$\frac{\Delta x_5}{\Delta x_{20}} = \frac{\tfrac{1}{2} a_{5,x} (\Delta t)^2}{\tfrac{1}{2} a_{20,x} (\Delta t)^2} = \frac{a_{5,x}}{a_{20,x}}$$

Use the result of Part (*a*) to obtain:

$$a_{5,x} = 2a_{20,x}$$

Let $a_{20,x} = a$. Then $a_{5,x} = 2a$ and the force equations become:

$$2T = m_{20} a$$

and

$$m_5 g - T = m_5 (2a)$$

Eliminate T between the two equations to obtain:

$$a = a_{20,x} = \frac{m_5 g}{2m_5 + \tfrac{1}{2} m_{20}}$$

Substitute numerical values and evaluate $a_{20,x}$ and $a_{5,x}$:

$$a_{20,x} = \frac{(5.0\,\text{kg})(9.81\,\text{m/s}^2)}{2(5.0\,\text{kg}) + \tfrac{1}{2}(20\,\text{kg})} = 2.45\,\text{m/s}^2$$

$$= \boxed{2.5\,\text{m/s}^2}$$

and

$$a_5 = 2(2.45\,\text{m/s}^2) = \boxed{4.9\,\text{m/s}^2}$$

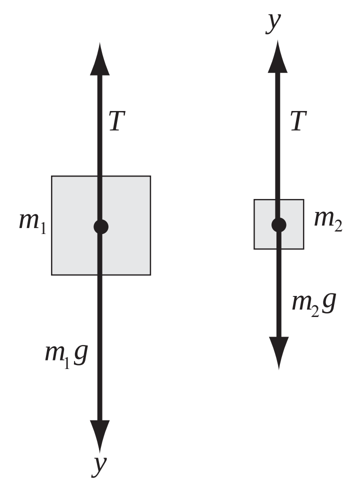
Substitute for either of the accelerations in either of the force equations and solve for T:

$$T = \boxed{25\,\text{N}}$$

82 •• The apparatus in Figure 4-60 is called an *Atwood's machine* and is used to measure the free-fall acceleration g by measuring the acceleration of the two blocks connected by a string over a pulley. Assume a massless, frictionless pulley and a massless string. (*a*) Draw a free-body diagram of each block. (*b*) Use the free-body diagrams and Newton's laws to show that the magnitude of the acceleration of either block and the tension in the string are $a = (m_1 - m_2)g/(m_1 + m_2)$ and $T = 2m_1 m_2 g/(m_1 + m_2)$. (*c*) Do these expressions give plausible results if $m_1 = m_2$, in the limit that $m_1 >> m_2$, and in the limit that $m_1 << m_2$? Explain.

Picture the Problem Assume that $m_1 > m_2$. Choose a coordinate system in which the $+y$ direction is downward for the block whose mass is m_1 and upward for the block whose mass is m_2 and draw free-body diagrams for each block. Apply Newton's second law to both blocks and solve the resulting equations simultaneously.

(*a*) The free-body diagrams for the two blocks are shown to the right:



(*b*) Apply $\sum F_y = ma_y$ to the block whose mass is m_2:

$$T - m_2 g = m_2 a_{2y} \quad (1)$$

Apply $\sum F_y = ma_y$ to the block whose mass is m_1:

$$m_1 g - T = m_1 a_{1y} \quad (2)$$

Because the blocks are connected by a taut string, they have the same acceleration. Let a represent their common acceleration. Then equations (1) and (2) become:

$$T - m_2 g = m_2 a$$
and
$$m_1 g - T = m_1 a$$

Adding these equations eliminates T and yields:

$$m_1 g - m_2 g = m_1 a + m_2 a$$

Solve for a to obtain:

$$a = \boxed{\frac{m_1 - m_2}{m_1 + m_2} g} \quad (3)$$

Substituting for a in either of the force equations and solving for T yields:

$$T = \boxed{\frac{2m_1 m_2 g}{m_1 + m_2}} \quad (4)$$

(*c*) For $m_1 = m_2$, equations (3) and (4) become:

$a = \dfrac{0}{m_1 + m_2} g = 0$ and $T = mg$ … as expected.

Divide the numerators and denominators if equations (3) and (4) by m_1 to obtain:

$$a = \left(\frac{1 - \frac{m_2}{m_1}}{1 + \frac{m_2}{m_1}}\right) g \text{ and } T = \left(\frac{2m_2}{1 + \frac{m_2}{m_1}}\right) g$$

For $m_1 >> m_2$ these equations become:

$a = g$ and $T = 2m_2 g$ … as expected.

Divide the numerators and denominators if equations (3) and (4) by m_2 to obtain:

$$a = \left(\frac{\frac{m_1}{m_2} - 1}{\frac{m_1}{m_2} + 1}\right) g \text{ and } T = \frac{2m_1 g}{\frac{m_1}{m_2} + 1}$$

For $m_1 << m_2$ these equations become:

$a = -g$ and $T = 2m_1 g$ … as expected.

83 •• If one of the masses of the Atwood's machine in Figure 4-60 is 1.2 kg, what should be the other mass so that the displacement of either mass during the first second following release is 0.30 m? Assume a massless, frictionless pulley and a massless string.

Picture the Problem The acceleration can be found from the given displacement during the first second. The ratio of the two masses can then be found from the acceleration using the first of the two equations derived in Problem 82 relating the acceleration of the Atwood's machine to its masses.

From Problem 82 we have:

$$a = \left(\frac{m_1 - m_2}{m_1 + m_2}\right) g$$

Solving for m_1 yields:

$$m_1 = m_2 \left(\frac{g + a}{g - a}\right) \quad (1)$$

Using a constant-acceleration equation, relate the displacement of the masses to their acceleration and solve for the acceleration:

$$\Delta y = v_{0y} t + \tfrac{1}{2} a_y (\Delta t)^2$$

or, because $v_{0y} = 0$,

$$\Delta y = \tfrac{1}{2} a_y (\Delta t)^2 \Rightarrow a_y = \frac{2\Delta y}{(\Delta t)^2}$$

Substitute numerical values and evaluate a:

$$a_y = \frac{2(0.30\,\text{m})}{(1.0\,\text{s})^2} = 0.600\,\text{m/s}^2$$

Substitute numerical values in equation (1) to obtain:

$$m_1 = m_2\left(\frac{9.81\text{ m/s}^2 + 0.600\text{ m/s}^2}{9.81\text{ m/s}^2 - 0.600\text{ m/s}^2}\right) = 1.13m_2$$

Find the second value for m_2 for m_1 = 1.2 kg:

$$m_2 = \boxed{1.4\text{ kg or }1.1\text{ kg}}$$

84 ••• The acceleration of gravity g can be determined by measuring the time t it takes for a mass m_2 in an Atwood's machine described in Problem 82 to fall a distance L, starting from rest. (*a*) Using the results of Problem 82 (Note the acceleration is constant.), find an expression for g in terms of m_1, m_2, L, and t. (*b*) Show that a small error in the time measurement dt, will lead to an error in g by an amount dg given by $dg/g = -2dt/t$. (*c*) Assume that the only significant uncertainty in the experimental measurements is the time of fall. If L = 3.00 m and m_1 is 1.00 kg, find the value of m_2 such that g can be measured with an accuracy of ±5% with a time measurement that is accurate to ±0.1 s.

Picture the Problem Use a constant-acceleration equation to relate the displacement of the descending (or rising) mass as a function of its acceleration and then use one of the results from Problem 82 to relate a to g. Differentiation of our expression for g will allow us to relate uncertainty in the time measurement to uncertainty in the measured value for g … and to the values of m_2 that would yield an experimental value for g that is good to within ±5%.

(*a*) From Problem 82 we have:

$$a = \left(\frac{m_1 - m_2}{m_1 + m_2}\right)g$$

Solving for g yields:

$$g = a\left(\frac{m_1 + m_2}{m_1 - m_2}\right) \qquad (1)$$

Using a constant-acceleration equation, express the displacement, L, as a function of t:

$$\Delta y = L = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $\Delta t = t$,

$$L = \tfrac{1}{2}a_y t^2 \Rightarrow a_y = \frac{2L}{t^2} \qquad (2)$$

Substitute for a_y in equation (1) to obtain:

$$g = \boxed{\frac{2L}{t^2}\left(\frac{m_1 + m_2}{m_1 - m_2}\right)}$$

(*b*) Evaluate *dg*/*dt* to obtain:

$$\frac{dg}{dt} = -4Lt^{-3}\left(\frac{m_1 + m_2}{m_1 - m_2}\right) = \frac{-2}{t}\left[\frac{2L}{t^2}\right]\left(\frac{m_1 + m_2}{m_1 - m_2}\right) = \frac{-2g}{t}$$

Divide both sides of this expression by *g* and multiply both sides by *dt* to separate the variables:

$$\frac{dg}{g} = \boxed{-2\frac{dt}{t}}$$

(*c*) Because $\frac{dg}{g} = \pm 0.05$:

$$t = \left|\frac{-2dt}{dg/g}\right| = \left|\frac{-2(\pm 0.1\,\text{s})}{\pm 0.05}\right| = 4\,\text{s}$$

Substitute numerical values in equation (2) and evaluate *a*:

$$a_y = \frac{2(3.00\,\text{m})}{(4\,\text{s})^2} = 0.375\,\text{m/s}^2$$

Solve equation (1) for m_2 to obtain:

$$m_2 = \frac{g - a}{g + a}m_1$$

Evaluate m_2 with m_1 = 1.00 kg:

$$m_2 = \frac{9.81\,\text{m/s}^2 - 0.375\,\text{m/s}^2}{9.81\,\text{m/s}^2 + 0.375\,\text{m/s}^2}(1.00\,\text{kg}) \approx 0.9\,\text{kg}$$

Solve equation (1) for m_1 to obtain:

$$m_1 = m_2\left(\frac{g + a_y}{g - a_y}\right)$$

Substitute numerical values to obtain:

$$m_1 = (0.926\,\text{kg})\left(\frac{9.81\,\text{m/s}^2 + 0.375\,\text{m/s}^2}{9.81\,\text{m/s}^2 - 0.375\,\text{m/s}^2}\right) \approx 1\,\text{kg}$$

Because the masses are interchangeable:

$$m_2 = \boxed{0.9\,\text{kg or }1\,\text{kg}}$$

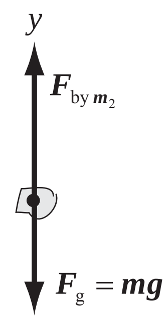
General Problems

85 •• A pebble of mass *m* rests on the block of mass m_2 of the ideal Atwood's machine in Figure 4-60. Find the force exerted by the pebble on the block of mass m_2.

Picture the Problem We can apply Newton's second law to the pebble and use the expression for the acceleration derived in Problem 82 to find the force $\vec{F}_{\text{by}\,m_2}$

exerted by the block of mass m_2 on the pebble. The forces $\vec{\boldsymbol{F}}_{\text{on}\,\boldsymbol{m}_2}$ exerted by the pebble on the block of mass m_2 and $\vec{\boldsymbol{F}}_{\text{by}\,\boldsymbol{m}_2}$ exerted by the block on the pebble constitute a third law pair and are equal in magnitude.

(*a*) The upward direction has been chosen as the $+y$ direction in the free-body diagram for the pebble shown to the right. The forces acting on the pebble are the force exerted by the object whose mass is m_2 ($\vec{\boldsymbol{F}}_{\text{by}\ m_2}$) and the gravitational force ($\vec{\boldsymbol{F}}_{\text{g}} = m\vec{\boldsymbol{g}}$) exerted by Earth.



(*b*) Apply $\sum F_y = ma_y$ to the pebble to obtain:

$$F_{\text{by}\,m_2} - mg = ma \Rightarrow F_{\text{by}\,m_2} = m(a+g)$$

Because $\vec{\boldsymbol{F}}_{\text{by}\,\boldsymbol{m}_2}$ and $\vec{\boldsymbol{F}}_{\text{on}\ m_2}$ constitute a third law pair:

$$F_{\text{on}\,m_2} = m(a+g) \qquad (1)$$

From Problem 82, the acceleration of the blocks is given by:

$$a = \frac{m_1 - m_2}{m_1 + m_2}g$$

With a pebble of mass m resting on the block of mass m_2, the expression for the acceleration becomes:

$$a = \frac{m_1 - (m+m_2)}{m_1 + (m+m_2)}g$$

Substituting for a in equation (1) and simplifying yields:

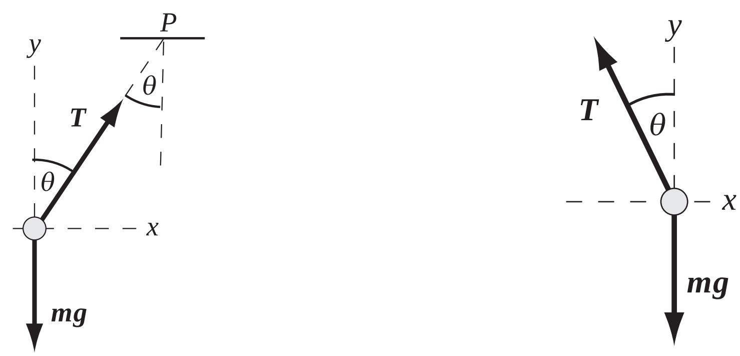
$$F_{\text{on}\,m_2} = m\left[\frac{m_1 - (m+m_2)}{m_1 + (m+m_2)}g + g\right] = mg\left[\frac{m_1 - m - m_2}{m_1 + m + m_2} + 1\right]$$

$$= \boxed{\left(\frac{2mm_1}{m + m_1 + m_2}\right)g}$$

86 •• A simple accelerometer can be made by suspending a small massive object from a string attached to a fixed point on an accelerating object. Suppose such an accelerometer is attached to point P on the ceiling of an automobile traveling in a straight line on a flat surface at constant acceleration. Due to the acceleration, the string will make an angle θ with the vertical. (*a*) Show that the magnitude of the acceleration a is related to the angle θ by $a = g \tan \theta$. (*b*) Suppose the automobile brakes steadily to rest from 50 km/h over a distance of 60 m. What angle will the string make with the vertical? Will the suspended

object be positioned below and ahead or below and behind point P during the braking?

Picture the Problem The free-body diagram shown below and to the left shows the forces acting on an object suspended from the ceiling of a car that is gaining speed to the right. Choose the coordinate system shown and use Newton's second law and constant- acceleration equations to describe the influence of the forces acting on the suspended object on its motion. The forces acting on the object are the gravitational force $m\vec{g}$ and the tension in the string $\vec{T}$. The free-body diagram shown to the right shows the forces acting on an object suspended from the ceiling of a car that is braking while moving to the right.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the object:

$$\sum F_x = T\sin\theta = ma_x$$

and

$$\sum T_y = T\cos\theta - mg = 0$$

Take the ratio of these two equations to eliminate T and m:

$$\frac{T\sin\theta}{T\cos\theta} = \frac{ma_x}{mg}$$

or

$$\tan\theta = \frac{a_x}{g} \Rightarrow a_x = \boxed{g\tan\theta}$$

(*b*) Solve the equation derived in (*a*) for θ:

$$\theta = \tan^{-1}\left(\frac{a_x}{g}\right) \qquad (2)$$

Using a constant-acceleration equation, express the velocity of the car in terms of its acceleration and solve for the acceleration:

$$v_x^2 = v_{0x}^2 + 2a_x\Delta x$$

or, because $v_x = 0$,

$$0 = v_{0x}^2 + 2a_x\Delta x \Rightarrow a_x = \frac{-v_{0x}^2}{2\Delta x}$$

Substitute for a_x in equation (2) and simplify to obtain:

$$\theta = \tan^{-1}\left(\frac{\dfrac{-v_{0x}^2}{2\Delta x}}{g}\right) = \tan^{-1}\left(\frac{-v_{0x}^2}{2g\Delta x}\right)$$

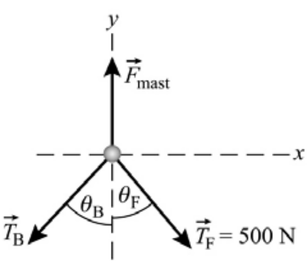
Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left(\frac{-\left(50\,\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{2\left(9.81\,\frac{\text{m}}{\text{s}^2}\right)(60\,\text{m})}\right)$$
$$= \boxed{9.3°}$$

The suspended object will be positioned below and ahead (by 9.3°) of point P during the braking.

87 •• **[SSM]** The mast of a sailboat is supported at bow and stern by stainless steel wires, the forestay and backstay, anchored 10 m apart (Figure 4-61). The 12.0-m-long mast weighs 800 N and stands vertically on the deck of the boat. The mast is positioned 3.60 m behind where the forestay is attached. The tension in the forestay is 500 N. Find the tension in the backstay and the force that the mast exerts on the deck.

Picture the Problem The free-body diagram shows the forces acting at the top of the mast. Choose the coordinate system shown and use Newton's second and third laws of motion to analyze the forces acting on the deck of the sailboat.



Apply $\sum F_x = ma_x$ to the top of the mast:

$$T_\text{F}\sin\theta_\text{F} - T_\text{B}\sin\theta_\text{B} = 0$$

Find the angles that the forestay and backstay make with the vertical:

$$\theta_\text{F} = \tan^{-1}\left(\frac{3.60\,\text{m}}{12.0\,\text{m}}\right) = 16.7°$$

and

$$\theta_\text{B} = \tan^{-1}\left(\frac{6.40\,\text{m}}{12.0\,\text{m}}\right) = 28.1°$$

Solving the x-direction equation for T_B yields:

$$T_\text{B} = T_\text{F}\frac{\sin\theta_\text{F}}{\sin\theta_\text{B}}$$

Substitute numerical values and evaluate T_B:

$$T_B = (500\,\text{N})\frac{\sin 16.7°}{\sin 28.1°} = \boxed{305\,\text{N}}$$

Apply $\sum F_y = 0$ to the mast:

$$\sum F_y = F_{\text{mast}} - T_F \cos\theta_F - T_B \cos\theta_B = 0$$

Solve for F_{mast} to obtain:

$$F_{\text{mast}} = T_F \cos\theta_F + T_B \cos\theta_B$$

Substitute numerical values and evaluate F_{mast}:

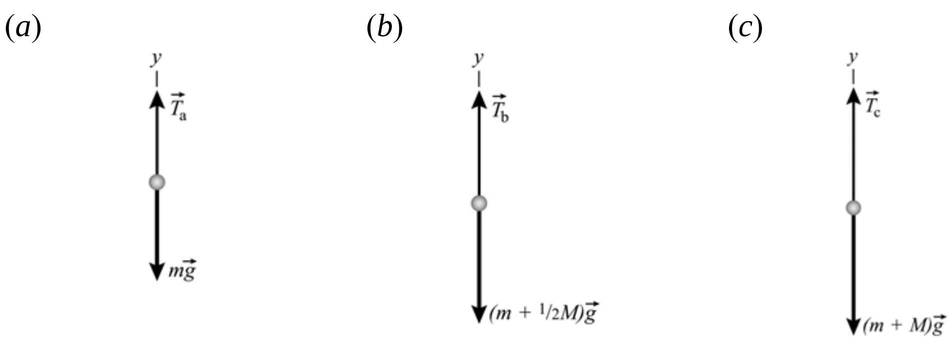
$$F_{\text{mast}} = (500\,\text{N})\cos 16.7° + (305\,\text{N})\cos 28.1° = 748\,\text{N}$$

The force that the mast exerts on the deck is the sum of its weight and the downward forces exerted on it by the forestay and backstay:

$$F_{\substack{\text{mast on}\\\text{the deck}}} = 748\,\text{N} + 800\,\text{N} = \boxed{1.55\,\text{kN}}$$

88 •• A 50-kg block is suspended from a uniform chain that is hanging from the ceiling. The mass of the chain itself is 20 kg, and the length of the chain is 1.5 m. Determine the tension in the chain (*a*) at the point where the chain is attached to the block, (*b*) midway up the chain, and (*c*) at the point where the chain is attached to the ceiling.

Picture the Problem Let m be the mass of the block and M be the mass of the chain. The free-body diagrams shown below display the forces acting at the locations identified in the problem. We can apply Newton's second law with $a_y = 0$ to each of the segments of the chain to determine the tensions.



(*a*) Apply $\sum F_y = ma_y$ to the block and solve for T_a:

$$T_a - mg = ma_y$$

or, because $a_y = 0$,

$$T_a = mg$$

Substitute numerical values and evaluate T_a:

$$T_a = (50\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{0.49\,\text{kN}}$$

(*b*) Apply $\sum F_y = ma_y$ to the block and half the chain and solve for T_b:

$$T_b - \left(m + \frac{M}{2}\right)g = ma_y$$

or, because $a_y = 0$,

$$T_b = \left(m + \frac{M}{2}\right)g$$

Substitute numerical values and evaluate T_b:

$$T_b = (50\,\text{kg} + 10\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{0.59\,\text{kN}}$$

(*c*) Apply $\sum F_y = ma_y$ to the block and chain and solve for T_c:

$$T_c - (m + M)g = ma_y$$

or, because $a_y = 0$,

$$T_c = (m + M)g$$

Substitute numerical values and evaluate T_c:

$$T_c = (50\,\text{kg} + 20\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{0.69\,\text{kN}}$$

89 •• The speed of the head of a redheaded woodpecker reaches 5.5 m/s before impact with the tree. If the mass of the head is 0.060 kg and the average force on the head during impact is 0.060 N, find (*a*) the acceleration of the head (assuming constant acceleration), (*b*) the depth of penetration into the tree, and (*c*) the time it takes for the head to come to a stop.

Picture the Problem (*a*) Choose a coordinate system in which the +*x* direction is the direction in which the woodpecker's head is moving and apply Newton's second law to the woodpecker's head to find its acceleration. (*b*) Because we've assumed constant acceleration, we can use a constant-acceleration equation to find the depth of penetration in the tree. In Part (*c*), we can the constant-acceleration equation $v_x = v_{0x} + a_x\Delta t$ to find the time it takes for the head to come to a stop.

(*a*) Apply $\sum F_x = ma_x$ to the woodpecker's head to obtain:

$$F_{\text{on the head}} = ma_x \Rightarrow a_x = \frac{F_{\text{on the head}}}{m}$$

Substitute numerical values and evaluate a_x:

$$a_x = \frac{-6.0\,\text{N}}{0.060\,\text{kg}} = \boxed{-0.10\,\text{km/s}^2}$$

(*b*) Use a constant-acceleration equation to relate the depth of penetration to the initial speed of the head and its acceleration:

$$v_x^2 = v_{0x}^2 + 2a_x\Delta x \Rightarrow \Delta x = \frac{v_x^2 - v_{0x}^2}{2a_x}$$

Because $v_x = 0$:

$$\Delta x = \frac{-v_{0x}^2}{2a_x}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{-(5.5\ \text{m/s})^2}{2(-0.10\ \text{km/s}^2)} = \boxed{15\ \text{cm}}$$

(*c*) Apply a constant-acceleration equation to relate the stopping time of the head to its initial and final speeds and to its acceleration:

$$v_x = v_{0x} + a_x\Delta t \Rightarrow \Delta t = \frac{v_x - v_{0x}}{a_x}$$

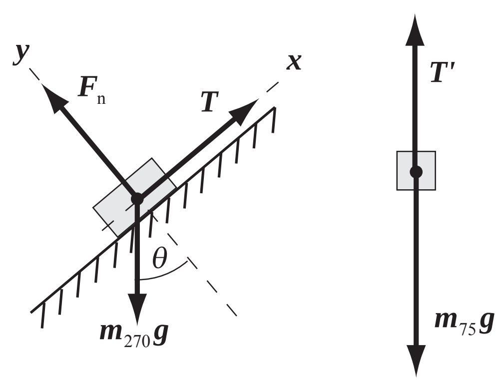
Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{0 - 5.5\ \text{m/s}}{-0.10\ \text{km/s}^2} = \boxed{55\ \text{ms}}$$

90 •• A frictionless surface is inclined at an angle of 30.0º to the horizontal. A 270-g block on the ramp is attached to a 75.0-g block using a pulley, as shown in Figure 4-62. (*a*) Draw two free-body diagrams, one for the 270-g block and the other for the 75.0-g block. (*b*) Find the tension in the string and the acceleration of the 270-g block. (*c*) The 270-g block is released from rest. How long does it take for it to slide a distance of 1.00 m along the surface? Will it slide up the incline, or down the incline?

Picture the Problem The application of Newton's second law to the block and the hanging weight will lead to simultaneous equations in their common acceleration *a* and the tension *T* in the cord that connects them. Once we know the acceleration
of this system, we can use a constant-acceleration equation to predict how long it takes the block to travel 1.00 m from rest. Note that the magnitudes of $\vec{T}$ and $\vec{T}'$ are equal.

(*a*) The free-body diagrams are shown to the right. m_{270} represents the mass of the 270-g block and m_{75} the mass of the 75.0-g block.



(*b*) Apply $\sum F_x = ma_x$ to the block and the suspended mass:

$$T - m_{270}g\sin\theta = m_{270}a_{1x}$$
and
$$m_{75}g - T = m_{75}a_{2x}$$

Letting a represent the common acceleration of the two objects, eliminate T between the two equations and solve a:

$$a = \frac{m_{75} - m_{270}\sin\theta}{m_{270} + m_{75}} g$$

Substitute numerical values and evaluate a:

$$a = \frac{0.0750\,\text{kg} - (0.270\,\text{kg})\sin 30°}{0.0750\,\text{kg} + 0.270\,\text{kg}}\left(9.81\,\text{m/s}^2\right) = -1.706\,\text{m/s}^2 = \boxed{-1.71\,\text{m/s}^2}$$

where the minus sign indicates that the acceleration is down the incline.

Substitute for a in either of the force equations to obtain:

$$T = \boxed{0.864\,\text{N}}$$

(c) Using a constant-acceleration equation, relate the displacement of the block down the incline to its initial speed and acceleration:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$

or, because $v_{0x} = 0$,

$$\Delta x = \tfrac{1}{2}a_x(\Delta t)^2 \Rightarrow \Delta t = \sqrt{\frac{2\Delta x}{a_x}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \sqrt{\frac{2(-1.00\,\text{m})}{-1.706\,\text{m/s}^2}} = \boxed{1.08\,\text{s}}$$

Because the block is released from rest and its acceleration is negative, it will slide down the incline.

91 •• A box of mass m_1 is pulled along a frictionless horizontal surface by a horizontal force F that is applied to the end of a rope of mass m_2 (see Figure 4-63). Neglect any sag of the rope. (a) Find the acceleration of the rope and block, assuming them to be one object. (b) What is the net force acting on the rope? (c) Find the tension in the rope at the point where it is attached to the block.

Picture the Problem Note that, while the mass of the rope is distributed over its length, the rope and the block have a common acceleration. Because the surface is horizontal and smooth, the only force that influences our solution is $\vec{F}$. The figure misrepresents the situation in that each segment of the rope experiences a gravitational force; the combined effect of which is that the rope must sag.

(a) Apply $\vec{a} = \vec{F}_{\text{net}}/m_{\text{tot}}$ to the rope-block system to obtain:

$$a = \boxed{\frac{F}{m_1 + m_2}}$$

(*b*) Apply $\sum \vec{F} = m\vec{a}$ to the rope, substitute the acceleration of the system obtained in (*a*), and simplify to obtain:

$$F_{net} = m_2 a = m_2\left(\frac{F}{m_1 + m_2}\right)$$

$$= \boxed{\frac{m_2}{m_1 + m_2}F}$$

(*c*) Apply $\sum \vec{F} = m\vec{a}$ to the block, substitute the acceleration of the system obtained in (*a*), and simplify to obtain:

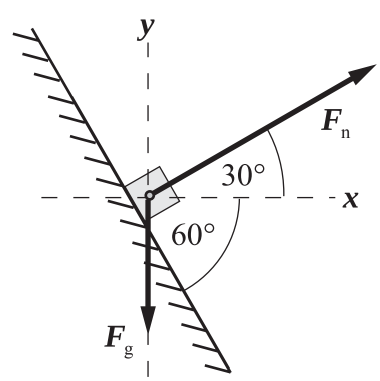
$$T = m_1 a = m_1\left(\frac{F}{m_1 + m_2}\right)$$

$$= \boxed{\frac{m_1}{m_1 + m_2}F}$$

92 •• A 2.0-kg block rests on a frictionless wedge that has a 60º incline and an acceleration $\vec{a}$ to the right such that the mass remains stationary relative to the wedge (Figure 4-64). (*a*) Draw the free body diagram of the block and use it to determine the magnitude of the acceleration. (*b*) What would happen if the wedge were given an acceleration larger than this value? Smaller than this value?

Picture the Problem We can apply Newton's second law to the 2-0-kg block to determine the magnitude of its acceleration.

(*a*) The free-body diagram of the 2.0-kg block is shown to the right. Because the surface of the wedge is frictionless, the force it exerts on the block must be normal to its surface. The forces acting on the block are the normal force $\vec{F}_n$ exerted by the frictionless surface and the gravitational force $\vec{F}_g$. The direction of the acceleration of the wedge has been chosen as the +*x* direction.



(*a*) Apply $\sum F_y = ma_y$ to the block to obtain:

$$F_n \sin 30° - F_g = ma_y$$

or, because $a_y = 0$ and $F_g = mg$,

$$F_n \sin 30° = mg \qquad (1)$$

Apply $\sum F_x = ma_x$ to the block:

$$F_n \cos 30° = ma_x \qquad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{a_x}{g} = \cot 30° \Rightarrow a_x = \frac{g}{\tan 30°}$$

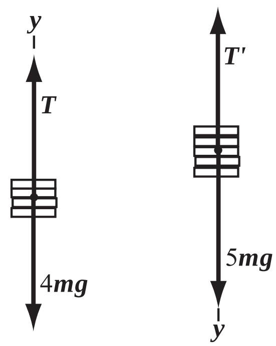
Substitute numerical values and evaluate a_x:

$$a_x = \frac{9.81\,\text{m/s}^2}{\tan 30°} = \boxed{17\,\text{m/s}^2}$$

(*b*) An acceleration of the wedge greater than $g/\tan 30°$ would require that the normal force exerted on the body by the wedge be greater than that given in Part (*a*); that is, $F_n > mg/\sin 30°$. Under this condition, there would be a net force in the *y* direction and the block would accelerate up the wedge. With an acceleration less than $g/\tan 30°$, the block would accelerate down the wedge.

93 ••• [SSM] The masses attached to each side of an ideal Atwood's machine consist of a stack of five washers, each of mass *m*, as shown in Figure 4-65. The tension in the string is T_0. When one of the washers is removed from the left side, the remaining washers accelerate and the tension decreases by 0.300 N. (*a*) Find *m*. (*b*) Find the new tension and the acceleration of each mass when a second washer is removed from the left side.

Picture the Problem Because the system is initially in equilibrium, it follows that $T_0 = 5mg$. When one washer is removed from the left side the remaining washers on the left side will accelerate upward (and those on the right side downward) in response to the net force that results. The free-body diagrams show the forces under this unbalanced condition. Applying Newton's second law to each collection of washers will allow us to determine both the acceleration of the system and the mass of a single washer.



(*a*) Apply $\sum F_y = ma_y$ to the rising washers:

$$T - 4mg = (4m)a_y \qquad (1)$$

Noting that $T = T'$, apply $\sum F_y = ma_y$ to the descending masses:

$$5mg - T = (5m)a_y \qquad (2)$$

Eliminate *T* between these equations to obtain:

$$a_y = \tfrac{1}{9}g$$

Use this acceleration in equation (1) or equation (2) to obtain:

$$T = \frac{40}{9}mg$$

Expressing the difference ΔT between T_0 and *T* yields:

$$\Delta T = 5mg - \frac{40}{9}mg \Rightarrow m = \frac{\frac{9}{5}\Delta T}{g}$$

Substitute numerical values and evaluate m:

$$m = \frac{\frac{9}{5}(0.300\,\text{N})}{9.81\,\text{m/s}^2} = \boxed{55.0\,\text{g}}$$

(b) Proceed as in (a) to obtain:

$$T - 3mg = 3ma_y \text{ and } 5mg - T = 5ma_y$$

Add these equations to eliminate T and solve for a_y to obtain:

$$a_y = \tfrac{1}{4}g$$

Substitute numerical values and evaluate a_y:

$$a_y = \tfrac{1}{4}(9.81\,\text{m/s}^2) = \boxed{2.45\,\text{m/s}^2}$$

Eliminate a_y in either of the motion equations and solve for T to obtain:

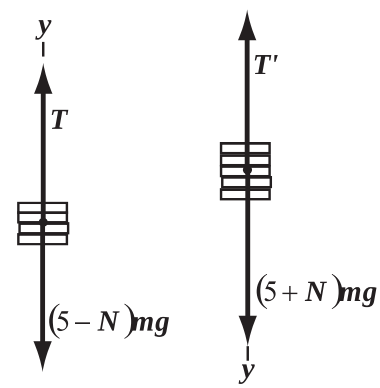
$$T = \tfrac{15}{4}mg$$

Substitute numerical values and evaluate T:

$$T = \tfrac{15}{4}(0.05505\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{2.03\,\text{N}}$$

94 •• Consider the ideal Atwood's machine in Figure 4-65. When N washers are transferred from the left side to the right side, the right side drops 47.1 cm in 0.40 s. Find N.

Picture the Problem The free-body diagram represents the Atwood's machine with N washers moved from the left side to the right side. Application of Newton's second law to each collection of washers will result in two equations that can be solved simultaneously to relate N, a, and g. The acceleration can then be found from the given data.



Apply $\sum F_y = ma_y$ to the rising washers:

$$T - (5 - N)mg = (5 - N)ma_y$$

Noting that $T = T'$, apply $\sum F_y = ma_y$ to the descending washers:

$$(5 + N)mg - T = (5 + N)ma_y$$

Add these equations to eliminate T:

$$(5 + N)mg - (5 - N)mg = (5 - N)ma_y + (5 + N)ma_y$$

Solving for N yields:

$$N = \frac{5a_y}{g}$$

Using a constant-acceleration equation, relate the distance the washers fell to their time of fall:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$,

$$\Delta y = \tfrac{1}{2}a_y(\Delta t)^2 \Rightarrow a_y = \frac{2\Delta y}{(\Delta t)^2}$$

Substitute numerical values and evaluate a_y:

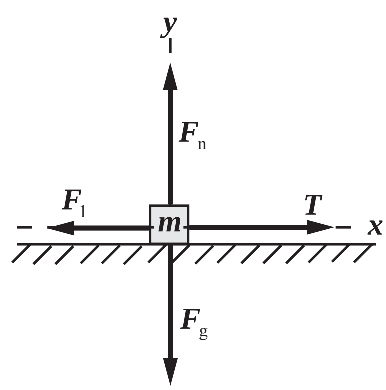
$$a_y = \frac{2(0.471\,\text{m})}{(0.40\,\text{s})^2} = 5.89\,\text{m/s}^2$$

Substitute in the expression for N:

$$N = 5\left(\frac{5.89\,\text{m/s}^2}{9.81\,\text{m/s}^2}\right) = \boxed{3}$$

95 •• Blocks of mass m and $2m$ are on a horizontal frictionless surface (Figure 4-66). The blocks are connected by a string. In addition, forces F_1 and F_2 are applied to the blocks as shown. (*a*) If the forces shown are constant, find the tension in the connecting string. (*b*) If the forces vary with time as $F_1 = Ct$ and $F_2 = 2Ct$, where $C = 5.00$ N/s and t is time, find the time t_0 at which the tension in the string equals 10.0 N.

Picture the Problem Draw the free-body diagram for the block of mass m and apply Newton's second law to obtain the acceleration of the system and then the tension in the rope connecting the two blocks.



(*a*) Apply $\sum F_x = ma_x$ to the block of mass m:

$$T - F_1 = ma_x \qquad (1)$$

Apply $\sum F_x = ma_x$ to both blocks:

$$F_2 - F_1 = (m + 2m)a = 3ma_x$$

Solving for a gives:

$$a_x = \frac{F_2 - F_1}{3m}$$

Substitute for a_x in the equation (1) to obtain:

$$T - F_1 = m\left(\frac{F_2 - F_1}{3m}\right)$$

Solving for T yields: $T = \boxed{\tfrac{1}{3}(F_2 + 2F_1)}$

(b) Substitute for F_1 and F_2 in the equation derived in Part (a):

$$T = \tfrac{1}{3}(2Ct + 2(Ct)) = \tfrac{4}{3}Ct \Rightarrow t = \frac{3T}{4C}$$

Substitute numerical values and evaluate $t = t_0$:

$$t_0 = \frac{3(10.0\ \text{N})}{4(5.00\ \text{N/s})} = \boxed{1.50\ \text{s}}$$

97 •• Elvis Presley, has supposedly been sighted numerous times after he passed away on August 16, 1977. The following is a chart of what Elvis' weight would be if he were sighted on the surface of other objects in our solar system. Use the chart to determine: (a) Elvis' mass on Earth, (b) Elvis' mass on Pluto, and (c) the acceleration due to gravity on Mars. (d) Compare the free-fall acceleration on Pluto to the free-fall acceleration on the moon.

planet	Elvis's weight (N)
Mercury	431
Venus	1031
Earth	1133
Mars	431
Jupiter	2880
Saturn	1222
Pluto	58
Moon	191

Picture the Problem Elvis' mass is the ratio of his weight on a given planet to the acceleration of gravity on that planet. In (b), (c), and (d) we can use the relationship between the gravitational force (weight) acting on an object, its mass (independent of location), and the local value of the free-fall acceleration.

(a) Elvis' mass on Earth is given by:

$$m = \frac{w_{\text{Earth}}}{g_{\text{Earth}}}$$

Substitute numerical values and evaluate m:

$$m = \frac{1131\ \text{N}}{9.81\ \text{m/s}^2} = 115.3\ \text{kg} = \boxed{115\ \text{kg}}$$

(b) Because his mass is independent of his location, Elvis' mass on Pluto is 115 kg.

(*c*) The free-fall acceleration on Mars is the ratio of the weight of an object on Mars to the mass of the object:

$$g_{\text{Mars}} = \frac{w_{\text{on Mars}}}{m}$$

Substitute numerical values for Elvis and evaluate g_{Mars}:

$$g_{\text{Mars}} = \frac{431\ \text{N}}{115.3\ \text{kg}} = \boxed{3.74\ \text{m/s}^2}$$

(*d*) The free-fall acceleration on Pluto is given by:

$$g_{\text{Pluto}} = \frac{w_{\text{on Pluto}}}{m} \qquad (1)$$

The free-fall acceleration on the moon is given by:

$$g_{\text{moon}} = \frac{w_{\text{on moon}}}{m} \qquad (2)$$

Divide equation (1) by equation (2) and simplify to obtain:

$$\frac{g_{\text{Pluto}}}{g_{\text{moon}}} = \frac{\dfrac{w_{\text{on Pluto}}}{m}}{\dfrac{w_{\text{on moon}}}{m}} = \frac{w_{\text{on Pluto}}}{w_{\text{on moon}}}$$

Substituting numerical values yields:

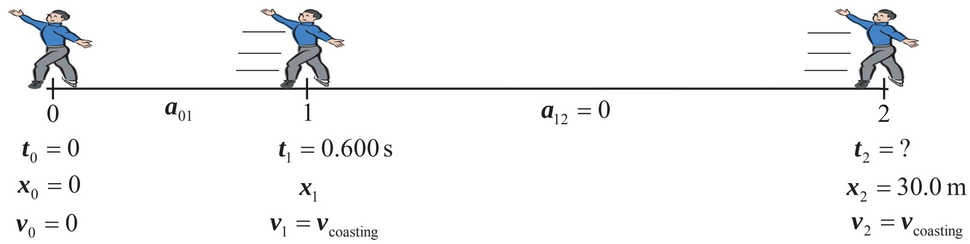
$$\frac{g_{\text{Pluto}}}{g_{\text{moon}}} = \frac{58\ \text{N}}{191\ \text{N}} = 0.30$$

or

$$g_{\text{Pluto}} = \boxed{0.30 g_{\text{moon}}}$$

97 ••• As a prank, your friends have kidnapped you in your sleep, and transported you out onto the ice covering a local pond. When you wake up you are 30.0 m from the nearest shore. The ice is so slippery (i.e. frictionless) that you can not seem to get yourself moving. You realize that you can use Newton's third law to your advantage, and choose to throw the heaviest thing you have, one boot, in order to get yourself moving. Take your weight to be 595 N. (*a*) What direction should you throw your boot so that you will most quickly reach the shore? (*b*) If you throw your 1.20-kg boot with an average force of 420 N, and the throw takes 0.600 s (the time interval over which you apply the force), what is the magnitude of the average force that the boot exerts on you? (Assume constant acceleration.) (*c*) How long does it take you to reach shore, including the short time in which you were throwing the boot?

Picture the Problem The diagram shown below summarizes the information about your trip to the shore and will be helpful in solving Part (*c*) of the problem.



(*a*) You should throw your boot in the direction away from the closest shore.

(*b*) The magnitude of the average force you exert on the boot equals the magnitude of the average force the boot exerts on you:

$$F_{\text{av, on you}} = \boxed{420\text{ N}}$$

(*c*) The time required for you to reach the shore is the sum of your travel time while accelerating and your travel time while coasting:

$$\Delta t_{\text{total}} = \Delta t_{01} + \Delta t_{12}$$

or, because $\Delta t_{01} = 0.600$ s,

$$\Delta t_{\text{total}} = 0.600\,\text{s} + \Delta t_{12} \qquad (1)$$

Use a constant-acceleration equation to relate your displacement Δx_{01} to your acceleration time Δt_{01}:

$$\Delta x_{01} = \tfrac{1}{2} a_{01} (\Delta t_{01})^2 \qquad (2)$$

Apply Newton's second law to express your acceleration during this time interval:

$$a_{01} = \frac{F_{\text{net}}}{m} = \frac{F_{\text{av}}}{w/g} = \frac{F_{\text{av}}g}{w}$$

Substitute numerical values and evaluate a_{01}:

$$a_{01} = \frac{(420\text{ N})(9.81\text{ m/s}^2)}{595\text{ N}} = 6.925\text{ m/s}^2$$

Substitute numerical values in equation (2) and evaluate Δx_{01}:

$$\Delta x_{01} = \tfrac{1}{2}(6.925\text{ m/s}^2)(0.600\text{ s})^2 = 1.246\text{ m}$$

Your coasting time is the ratio of your displacement while coasting to your speed while coasting:

$$\Delta t_{12} = \frac{\Delta x_{12}}{v_1}$$

or, because $\Delta \boldsymbol{x}_{12} = 30.0\text{ m} - \Delta \boldsymbol{x}_{01}$,

$$\Delta t_{12} = \frac{30.0\text{ m} - \Delta x_{01}}{v_1} \qquad (3)$$

Use a constant-acceleration equation to relate your terminal speed (your speed after the interval of acceleration) to your acceleration and displacement during this interval:

$$v_1 = v_0 + a_{01}\Delta t_{01}$$

or, because $v_0 = 0$,

$$v_1 = a_{01}\Delta t_{01}$$

Substitute for v_1 in equation (3) to obtain:

$$\Delta t_{12} = \frac{30.0\text{ m} - \Delta x_{01}}{a_{01}\Delta t_{01}}$$

Substituting for $\Delta t_{\text{coasting}}$ in equation (1) yields:

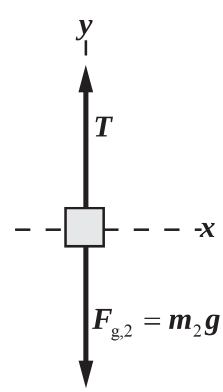
$$\Delta t_{\text{total}} = 0.600\text{ s} + \frac{30.0\text{ m} - \Delta x_{01}}{a_{01}\Delta t_{01}}$$

Substitute numerical values and evaluate Δt_{total}:

$$\Delta t_{\text{total}} = 0.600\text{ s} + \frac{30.0\text{ m} - 1.246\text{ m}}{(6.925\text{ m/s}^2)(0.600\text{ s})} = \boxed{7.52\text{ s}}$$

98 ••• The pulley of an ideal Atwood's machine is given an upward acceleration *a*, as shown in Figure 4-67. Find the acceleration of each mass and the tension in the string that connects them.

Picture the Problem Because a constant-upward acceleration has the same effect as an increase in the acceleration due to gravity, we can use the result of Problem 82 (for the tension) with *a* replaced by *a* + *g*. The application of Newton's second law to the object whose mass is m_2 will connect the acceleration of this body to tension from Problem 82.



In Problem 82 it is given that, when the support pulley is not accelerating, the tension in the rope and the acceleration of the masses are related according to:

$$\boxed{T = \frac{2m_1m_2}{m_1+m_2}g}$$

Replace *a* with *a* + *g*:

$$T = \frac{2m_1m_2}{m_1+m_2}(a+g)$$

Apply $\sum F_y = ma_y$ to the object whose mass is m_2:

$$T - m_2 g = m_2 a_2 \Rightarrow a_2 = \frac{T - m_2 g}{m_2}$$

Substitute for T and simplify to obtain:

$$a_2 = \boxed{\frac{(m_1 - m_2)g + 2m_1 a}{m_1 + m_2}}$$

The expression for a_1 is the same as for a_2 with all subscripts interchanged (note that a positive value for a_1 represents acceleration upward):

$$a_1 = \boxed{\frac{(m_2 - m_1)g + 2m_2 a}{m_1 + m_2}}$$

99 ••• You are working for an automotive magazine and putting a certain new automobile (mass 650 kg) through its paces. While accelerating from rest, its onboard computer records its speed as a function of time as follows:

v (m/s):	0	10	20	30	40	50
t (s):	0	1.8	2.8	3.6	4.9	6.5

(*a*) Using a **spreadsheet**, find the average acceleration over each 1.8-s time interval, and graph the velocity versus time and acceleration versus time for this car. (*b*) Where on the graph of velocity versus time is the net force on the car highest and lowest? Explain your reasoning. (*c*) What is the average net force on the car over the whole trip? (*d*) From the graph of velocity versus time, estimate the total distance covered by the car.

Picture the Problem

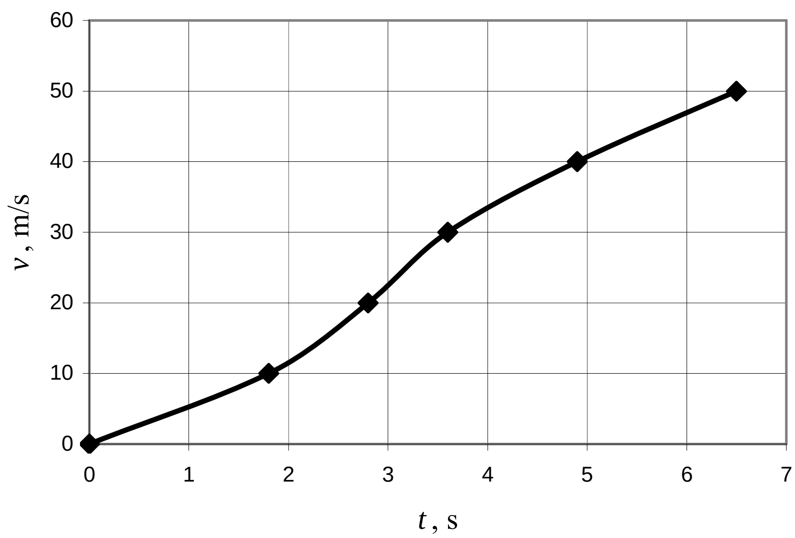
(*a*) A spreadsheet program is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
C1	650	m
D5	(B5−B4)/2	$\frac{1}{2}\Delta t$
E5	(C5−C4)/D5	$\frac{\Delta v}{\Delta t}$
F5	$D$1*E5	ma
F10	(F5+F6+F7+F8+F9)/5	F_{ave}

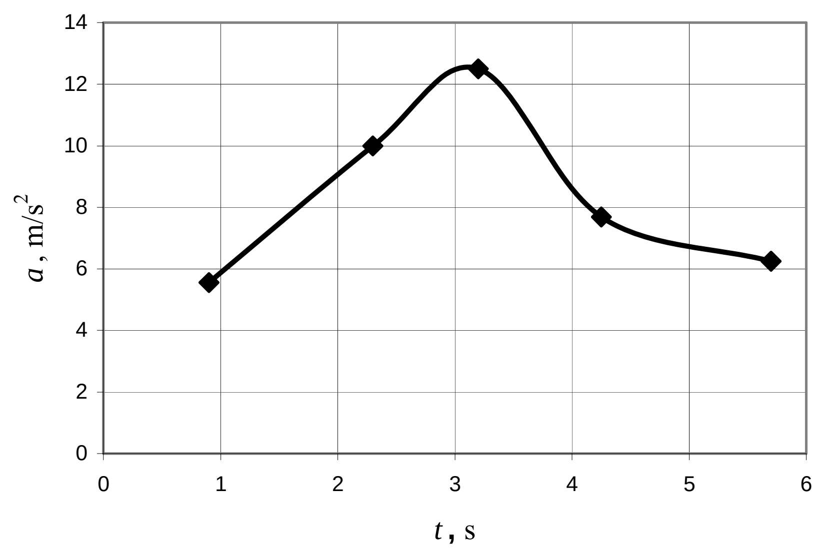
	A	B	C	D	E	F
1			m=	650	kg	
2						
3		t (s)	v (m/s)	t_{midpt} (s)	a (m/s^2)	$F = ma$ (N)
4		0.0	0			
5		1.8	10	0.90	5.56	3611
6		2.8	20	2.30	10.00	6500
7		3.6	30	3.20	12.50	8125
8		4.9	40	4.25	7.69	5000

9		6.5	50	5.70	6.25	4063
10						5460
11						

A graph of velocity as a function of time follows:



A graph of acceleration as a function of time is shown below:



(b) Because the net force is lowest where the acceleration is lowest, we can see from the graph of velocity versus time that its slope (the acceleration) is smallest in the interval from 0 to 1.8 s. Because the net force is highest where the acceleration is highest, we can see from the graph of velocity versus time that its slope (the acceleration) is greatest in the interval from 2.8 s to 3.6 s.

(*c*) From the table we see that:

$$F_{\text{ave}} \approx \boxed{5500\ \text{N}}$$

(*d*) The distance covered by the car is the area under the graph of velocity versus time. Because the graph of speed versus time is approximately linear, we can estimate the total distance covered by the car by finding the area of the triangular region under it.

$$A_{\text{triangle}} = \tfrac{1}{2}bh = \tfrac{1}{2}(6.5\ \text{s})(50\ \text{m/s})$$
$$\approx \boxed{160\ \text{m}}$$

Chapter 5
Additional Applications of Newton's Laws

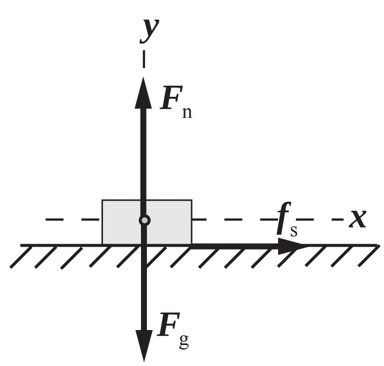
Conceptual Problems

1 • [SSM] Various objects lie on the bed of a truck that is moving along a straight horizontal road. If the truck gradually speeds up, what force acts on the objects to cause them to speed up too? Explain why some of the objects might stay stationary on the floor while others might slip backward on the floor.

Determine the Concept Static and kinetic frictional forces are responsible for the accelerations. If the coefficient of static friction between the truck bed and the object is sufficiently large, then the object will not slip on the truck bed. The larger the acceleration of the truck, the larger the coefficient of static friction that is needed to prevent slipping.

2 • Blocks made of the same material but differing in size lie on the bed of a truck that is moving along a straight horizontal road. All of the blocks will slide if the truck's acceleration is sufficiently great. How does the minimum acceleration at which a small block slips compare with the minimum acceleration at which a much heavier block slips?

Determine the Concept The forces acting on an object are the normal force exerted by the floor of the truck, the gravitational force exerted by Earth, and the friction force; also exerted by the floor of the truck. Of these forces, the only one that acts in the direction of the acceleration (chosen to be to the right) is the static friction force. Apply Newton's second law to the object to determine how the critical acceleration depends on its weight.



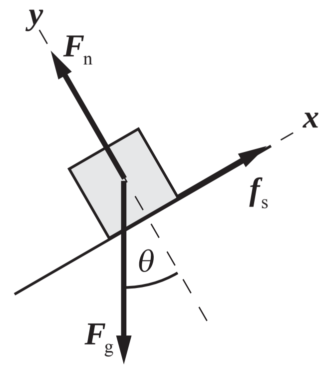
Taking the $+x$ direction to be to the right, apply $\Sigma F_x = ma_x$ to the object:

$$f_s = \mu_s F_g = \mu_s mg = ma_x \Rightarrow a_x = \mu_s g$$

Because a_x is independent of m and F_g, the critical accelerations are the same.

3 • A block of mass m rests on a plane that is inclined at an angle θ with the horizontal. It follows that the coefficient of static friction between the block and plane is (*a*) $\mu_s \geq g$, (*b*) $\mu_s = \tan\theta$, (*c*) $\mu_s \leq \tan\theta$, (*d*) $\mu_s \geq \tan\theta$.

Determine the Concept The forces acting on the block are the normal force $\vec{F}_n$ exerted by the incline, the weight of the block $\vec{F}_g$ exerted by Earth, and the static friction force $\vec{f}_s$ also exerted by the incline. We can use the definition of μ_s and the conditions for equilibrium to determine the relationship between μ_s and θ.



Apply $\sum F_x = ma_x$ to the block:

$$f_s - F_g \sin\theta = 0$$

or, because $F_g = mg$,

$$f_s - mg\sin\theta = 0 \qquad (1)$$

Apply $\sum F_y = ma_y$ in the y direction:

$$F_n - mg\cos\theta = 0 \qquad (2)$$

Divide equation (1) by equation (2) to obtain:

$$\tan\theta = \frac{f_s}{F_n}$$

Substitute for f_s ($\le \mu_s F_n$) and simplify to obtain:

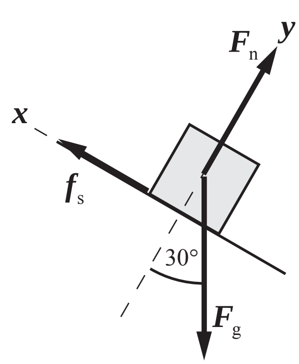
$$\tan\theta \le \frac{\mu_s F_n}{F_n} = \mu_s$$ and $\boxed{(d)}$ is correct.

4 • A block of mass m is at rest on a plane that is inclined at an angle of 30º with the horizontal, as shown in Figure 5-56. Which of the following statements about the magnitude of the static frictional force f_s is necessarily true? (a) $f_s > mg$. (b) $f_s > mg\cos 30º$. (c) $f_s = mg\cos 30º$. (d) $f_s = mg\sin 30°$. (e) None of these statements is true.

Determine the Concept The block is in equilibrium under the influence of $\vec{F}_n$, $\vec{F}_g$, and $\vec{f}_s$; that is,

$$\vec{F}_n + \vec{F}_g + \vec{f}_s = \mathbf{0}$$

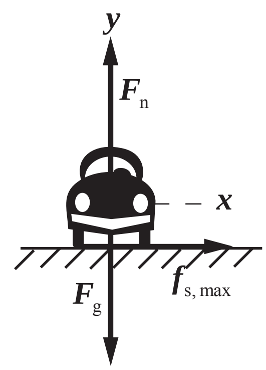
We can apply Newton's second law in the x direction to determine the relationship between f_s and $F_g = mg$.



Apply $\sum F_x = 0$ to the block to obtain: $f_s - mg\sin\theta = 0 \Rightarrow f_s = mg\sin\theta$ and $\boxed{(d)}$ is correct.

5 •• On an icy winter day, the coefficient of friction between the tires of a car and a roadway is reduced to one-quarter of its value on a dry day. As a result, the maximum speed $v_{\text{max dry}}$ at which the car can safely negotiate a curve of radius R is reduced. The new value for this speed is (*a*) $v_{\text{max dry}}$, (*b*) $0.71v_{\text{max dry}}$, (*c*) $0.50v_{\text{max dry}}$, (*d*) $0.25v_{\text{max dry}}$, (*e*) reduced by an unknown amount depending on the car's mass.

Picture the Problem The forces acting on the car as it rounds a curve of radius R at maximum speed are shown on the free-body diagram to the right. The centripetal force is the static friction force exerted by the roadway on the tires. We can apply Newton's second law to the car to derive an expression for its maximum speed and then compare the speeds under the two friction conditions described.



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = f_{\text{s,max}} = m\frac{v_{\text{max}}^2}{R}$$

and

$$\sum F_y = F_n - mg = 0$$

From the y equation we have: $F_n = mg$

Express $f_{\text{s,max}}$ in terms of F_n in the x equation and solve for v_{max} to obtain:

$$v_{\text{max}} = \sqrt{\mu_s gR} \qquad (1)$$

When $\mu_s = \mu'_s$:

$$v'_{\text{max}} = \sqrt{\mu'_s gR} \qquad (2)$$

Dividing equation (2) by equation (1) yields:

$$\frac{v'_{\text{max}}}{v_{\text{max}}} = \frac{\sqrt{\mu'_s gR}}{\sqrt{\mu_s gR}} = \sqrt{\frac{\mu'_s}{\mu_s}}$$

Solve for v'_{max} to obtain:

$$v'_{\text{max}} = \sqrt{\frac{\mu'_s}{\mu_s}}v_{\text{max}}$$

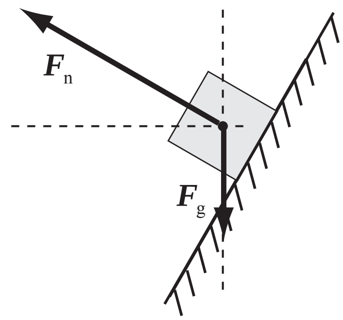
Evaluate $v'_{\max}$ for $\mu'_{s} = \frac{1}{4}\mu_{s}$:

$$v'_{\max} = \sqrt{\tfrac{1}{4}}v_{\max} = 0.5v_{\max} = 50\%v_{\max}$$

and $\boxed{(c)}$ is correct.

6 •• If it is started properly on the frictionless inside surface of a cone (Figure 5-57), a block is capable of maintaining uniform circular motion. Draw the free-body diagram of the block and identify clearly which force (or forces or force components) is responsible for the centripetal acceleration of the block.

Determine the Concept The forces acting on the block are the normal force $\vec{F}_{n}$ exerted by the surface of the cone and the gravitational force $\vec{F}_{g}$ exerted by Earth. The horizontal component of $\vec{F}_{n}$ is responsible for the centripetal force on the block.



7 •• Here is an interesting experiment that you can perform at home: take a wooden block and rest it on the floor or some other flat surface. Attach a rubber band to the block and pull gently and steadily on the rubber band in the horizontal direction. Keep your hand moving at constant speed. At some point, the block will start moving, but it will not move smoothly. Instead, it will start moving, stop again, start moving again, stop again, and so on. Explain why the block moves this way. (The start-stop motion is sometimes called ″stick-slip″ motion.)

Determine the Concept As the spring is extended, the force exerted by the spring on the block increases. Once that force exceeds the maximum value of the force of static friction, the block will slip. As it does, it will shorten the length of the spring, decreasing the force that the spring exerts. The force of kinetic friction then slows the block to a stop, which starts the cycle over again.

8 • Viewed from an inertial reference frame, an object is seen to be moving in a circle. Which, if any, of the following statements must be true. (*a*) A nonzero net force acts on the object. (*b*) The object cannot have a radially outward force acting on it. (*c*) At least one of the forces acting on the object must point directly toward the center of the circle.

(*a*) True. The velocity of an object moving in a circle is continually changing independently of whether the object's speed is changing. The change in the velocity vector and the acceleration vector and the net force acting on the object all point toward the center of circle. This center-pointing force is called a centripetal force.

(*b*) False. The only condition that must be satisfied in order that the object move along a circular path is that the *net* force acting on it be radially inward.

(*c*) False. The only condition that must be satisfied in order that the object move along a circular path is that the *net* force acting on it be radially inward.

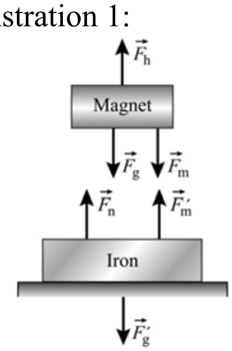
9 •• A particle is traveling in a vertical circle at constant speed. One can conclude that the magnitude of its _____ is(are) constant. (*a*) velocity, (*b*) acceleration, (*c*) net force, (*d*) apparent weight.

Determine the Concept A particle traveling in a vertical circle experiences a downward gravitational force plus an additional force that constrains it to move along a circular path. Because the speed of the particle is constant, the magnitude of its velocity is constant. Because the magnitude of its velocity is constant, its acceleration must be constant. Because the magnitude of its acceleration is constant, the magnitude of the net force acting on it must be constant. Therefore, $\boxed{(a)}$, $\boxed{(b)}$, and $\boxed{(c)}$ are correct.

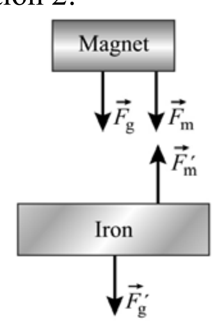
10 •• You place a lightweight piece of iron on a table and hold a small kitchen magnet above the iron at a distance of 1.00 cm. You find that the magnet cannot lift the iron, even though there is obviously a force between the iron and the magnet. Next, again holding the magnet 1.00 cm above the iron, you drop them from arm's length, releasing them from rest simultaneously. As they fall, the magnet and the piece of iron bang into each other before hitting the floor. (*a*) Draw free-body diagrams illustrating all of the forces on the magnet and the iron for each demonstration. (*b*) Explain why the magnet and iron move closer together while they are falling, even though the magnet cannot lift the piece of iron when it is sitting on the table.

Determine the Concept We can analyze these demonstrations by drawing force diagrams for each situation. In both diagrams, h denotes ″hand″, g denotes ″gravitational″, m denotes ″magnetic″, and n denotes ″normal.″

(*a*) Demonstration 1:



Demonstration 2:

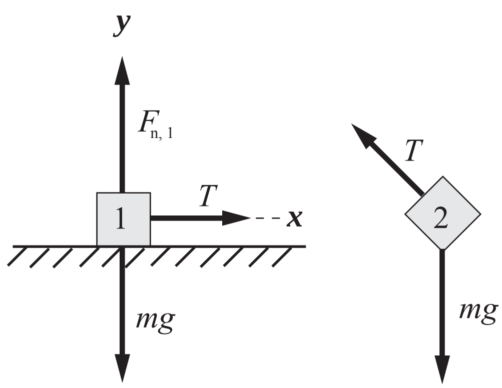


(*b*) Because the magnet doesn't lift the iron in the first demonstration, the force exerted on the iron must be less than its (the iron's) weight. This is still true when the two are falling, but the motion of the iron is not restrained by the table, and the

motion of the magnet is not restrained by the hand. Looking at the second diagram, the net force pulling the magnet down is greater than its weight, implying that its acceleration is greater than g. The opposite is true for the iron: the magnetic force acts upwards, slowing it down, so its acceleration will be less than g. Because of this, the magnet will catch up to the iron piece as they fall.

11 ••• [SSM] The following question is an excellent "braintwister" invented by Boris Korsunsky. Two identical blocks are attached by a massless string running over a pulley as shown in Figure 5-58. The rope initially runs over the pulley at the rope's midpoint, and the surface that block 1 rests on is frictionless. Blocks 1 and 2 are initially at rest when block 2 is released with the string taut and horizontal. Will block 1 hit the pulley before or after block 2 hits the wall? (Assume that the initial distance from block 1 to the pulley is the same as the initial distance from block 2 to the wall.) There is a very simple solution.

Picture the Problem The following free-body diagrams show the forces acting on the two objects some time after block 2 is dropped. Note that the tension in the string is the same on both sides of the pulley. The only force pulling block 2 to the left is the horizontal component of the tension. Because this force is smaller than the T and blocks 1 and 2 have the same mass, the acceleration of block 1 to the right will always be greater than the acceleration of block 2 to the left.



Because the initial distance from block 1 to the pulley is the same as the initial distance of block 2 to the wall, block 1 will hit the pulley before block 2 hits the wall.

12 •• In class, most professors do the following experiment while discussing the conditions under which air drag can be neglected while analyzing free-fall. First, a flat piece of paper and a small lead weight are dropped next to each other, and clearly the paper's acceleration is less than that of the lead weight. Then, the paper is crumpled into a small wad and the experiment repeated. Over the distance of a meter or two, it is clear the acceleration of the paper is now very close to that of the lead weight. To your dismay, the professor calls on you to explain why the paper's acceleration changed so dramatically. Repeat your explanation here!

Determine the Concept Air drag depends on the frontal area presented. Reducing it by crumpling the paper makes the force of air drag a lot less so that gravity is the most important force. The paper will thus accelerate at approximately *g* (until speeds are high enough for drag forces to come back into play in spite of the reduced area).

13 •• [SSM] Jim decides to attempt to set a record for terminal speed in skydiving. Using the knowledge he has gained from a physics course, he makes the following plans. He will be dropped from as high an altitude as possible (equipping himself with oxygen), on a warm day and go into a ″knife″ position in which his body is pointed vertically down and his hands are pointed ahead. He will outfit himself with a special sleek helmet and rounded protective clothing. Explain how each of these factors helps Jim attain the record.

Determine the Concept Air drag is proportional to the density of air and to the cross-sectional area of the object. On a warm day the air is less dense. The air is also less dense at high altitudes. Pointing his hands results in less area being presented to air drag forces and, hence, reduces them. Rounded and sleek clothing has the same effect as pointing his hands.

14 •• You are sitting in the passenger seat in a car driving around a circular, horizontal, flat racetrack at a high speed. As you sit there, you ″feel″ a ″force″ pushing you toward the outside of the track. What is the true direction of the force acting on you, and where does it come from? (Assume that you do not slide across the seat.) Explain the *sensation* of an "outward force" on you in terms of the Newtonian perspective.

Determine the Concept In your frame of reference (the accelerating reference frame of the car), the direction of the force must point toward the center of the circular path along which you are traveling; that is, in the direction of the centripetal force that keeps you moving in a circle. The friction between you and the seat you are sitting on supplies this force. The reason you seem to be "pushed" to the outside of the curve is that your body's inertia "wants", in accordance with Newton's first law (the law of inertia), to keep it moving in a straight line–that is, tangent to the curve.

15 • [SSM] The mass of the moon is only about 1% of that of Earth. Therefore, the force that keeps the moon in its orbit around Earth (*a*) is much smaller than the gravitational force exerted on the moon by Earth, (*b*) is much greater than the gravitational force exerted on the moon by Earth, (*c*) is the gravitational force exerted on the moon by Earth, (*d*) cannot be answered yet, because we have not yet studied Newton's law of gravity.

Determine the Concept The centripetal force that keeps the moon in its orbit around Earth is provided by the gravitational force Earth exerts on the moon. As described by Newton's 3rd law, this force is equal in magnitude to the force the

moon exerts on Earth. $\boxed{(c)}$ is correct.

16 • A block is sliding on a frictionless surface along a loop-the-loop, as in Figure 5-59. The block is moving fast enough so that it never loses contact with the track. Match the points along the track to the appropriate free-body diagrams in the figure.

Determine the Concept The only forces acting on the block are its weight and the force the surface exerts on it. Because the loop-the-loop surface is frictionless, the force it exerts on the block must be perpendicular to its surface.

At point A the weight is downward and the normal force is to the right. The normal force is the centripetal force. Free-body diagram 3 matches these forces.

At point B the weight is downward, the normal force is upward, and the normal force is greater than the weight so that their difference is the centripetal force. Free-body diagram 4 matches these forces.

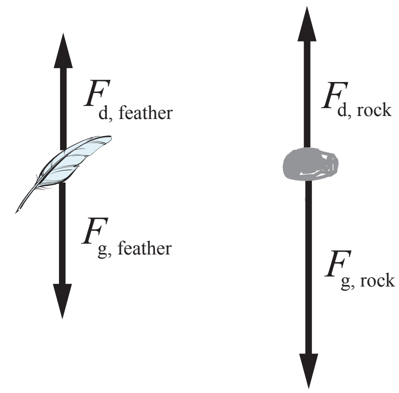
At point C the weight is downward and the normal force is to the left. The normal force is the centripetal force. Free-body diagram 5 matches these forces.

At point D both the weight and the normal forces are downward. Their sum is the centripetal force. Free-body diagram 2 matches these forces.

17 •• [SSM] (*a*) A rock and a feather held at the same height above the ground are simultaneously dropped. During the first few milliseconds following release, the drag force on the rock is smaller than the drag force on the feather, but later on during the fall the *opposite* is true. Explain. (*b*) In light of this result, explain how the rock's acceleration can be so obviously larger than that of the feather. *Hint*: *Draw a free-body diagram of each object*.

Determine the Concept The drag force

acting on the objects is given by $F_\text{d} = \frac{1}{2}CA\rho v^2$, where A is the projected surface area, v is the object's speed, ρ is the density of air, and C is a dimensionless coefficient. We'll assume that, over the height of the fall, the density of air ρ is constant. The free-body diagrams for a feather and a rock several milliseconds into their fall are shown to the right. The forces acting on both objects are the downward gravitational force and an upward drag force.



(a) The drag force is proportional to the area presented and some power of the speed. The drag force on the feather is larger because the feather presents a larger area than does the rock. As the rock gains speed, the drag force on it increases. The drag force on the rock eventually exceeds the drag force on the feather because the drag force on the feather cannot exceed the gravitational force on the feather.

A short time after being released the feather reaches terminal speed. During the rest of its fall the drag force on it is equal to the gravitational force acting on it. However, the gravitational force on the rock is much greater than the drag force on the feather, so the rock continues to gain speed long after the feather reaches terminal speed. As the rock continues to gain speed, the drag force on it continues to increase. As a result, the drag force on the rock eventually exceeds the drag force on the feather.

(b) Terminal speed is much higher for the rock than for the feather. The acceleration of the rock will remain high until its speed approaches its terminal speed.

18 •• Two pucks of masses m_1 and m_2 are lying on a frictionless table and are connected by a massless spring of force constant k. A horizontal force F_1 directed away from m_2 is then exerted on m_1. What is the magnitude of the resulting acceleration of the center of mass of the two-puck system? (a) F_1/m_1. (b) $F_1/(m_1 + m_2)$. (c) $(F_1 + kx)/(m_1 + m_2)$, where x is the amount the spring is stretched. (d) $(m_1 + m_2)F_1/m_1m_2$.

Determine the Concept The acceleration of the center of mass of a system of particles is described by $\vec{\boldsymbol{F}}_\text{net,ext} = \sum_\text{i} \vec{\boldsymbol{F}}_\text{i,ext} = M\vec{\boldsymbol{a}}_\text{cm}$, where M is the total mass of the system.

Express the acceleration of the center of mass of the two pucks:

$$a_{cm} = \frac{F_{net,ext}}{M} = \frac{F_1}{m_1 + m_2}$$

because the spring force is an internal force. $\boxed{(b)}$ is correct.

19 •• The two pucks in Problem 18 lie unconnected on a frictionless table. A horizontal force F_1 directed away from m_2 is then exerted on m_1. How does the magnitude of the resulting acceleration of the center of mass of the two-puck system compare to the magnitude of the acceleration of m_1? Explain your reasoning.

Determine the Concept The magnitude of the acceleration of the puck whose mass is m_1 is related to the net force F_1 acting on it through Newton's second law.

Because the pucks are no longer connected, the magnitude of the acceleration of the center of mass is:

$$a_{\text{CM, disconnected}} = \frac{F_1}{m_1}$$

From Problem 18:

$$a_{\text{CM, connected}} = \frac{F_1}{m_1 + m_2}$$

Because $\frac{F_1}{m_1} > \frac{F_1}{m_1 + m_2}$ the magnitude of the acceleration of m_1 is greater.

20 •• If only external forces can cause the center of mass of a system of particles to accelerate, how can a car on level ground ever accelerate? We normally think of the car's engine as supplying the force needed to accelerate the car, but is this true? Where does the external force that accelerates the car come from?

Determine the Concept There is only one force that can cause the car to move forward−the friction of the road! The car's engine causes the tires to rotate, but if the road were frictionless (as is closely approximated by icy conditions) the wheels would simply spin without the car moving anywhere. Because of friction, the car's tire pushes backwards against the road−from Newton's third law, the frictional force acting on the tire must then push it forward. This may seem odd, as we tend to think of friction as being a retarding force only, but it is true.

21 •• When we push on the brake pedal to slow down a car, a brake pad is pressed against the rotor so that the friction of the pad slows the wheel's rotation. However, the friction of the pad against the rotor *cannot be* the force that slows the car down, because it is an internal force (both the rotor and the wheel are parts of the car, so any forces between them are purely internal to the system). What is

the external force that slows down the car? Give a detailed explanation of how this force operates.

Determine the Concept The friction of the tire against the road causes the car to slow down. This is rather subtle, as the tire is in contact with the ground without slipping at all times, and so as you push on the brakes harder, the force of static friction of the road against the tires must increase.

22 •• Give an example of each of the following. (*a*) A three-dimensional object that has no matter at its center of mass. (*b*) A solid object whose center of mass is outside of it. (*c*) A solid sphere whose center of mass does not lie at its geometrical center. (*d*) A long wooden stick whose center of mass does not lie at its middle.

(*a*) A solid spherical shell, or donut, or tire.

(*b*) A solid hemispherical shell.

(*c*) Any sphere with one side a different density than the other, or a density variation that isn't radially symmetric.

(*d*) Any stick with a non-uniform and non-symmetric density variation. A baseball bat is a good example of such a stick.

23 •• **[SSM]** When you are standing upright, your center of mass is located within the volume of your body. However, as you bend over (say to pick up a package), its location changes. Approximately where is it when you are bent over at right angles and what change in your body caused the center of mass location to change? Explain.

Determine the Concept Relative to the ground, your center of mass moves downward. This is because some of your mass (hips) moved backward, some of your mass (your head and shoulders) moved forward, and the top half of your body moved downward.

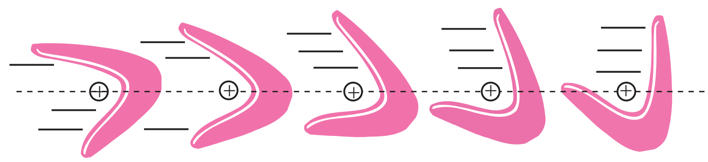
24 •• Early on their three-day (one-way) trip to the moon, the Apollo team (late 1960s to early 1970s) would explosively separate the lunar ship from the third-stage booster (that provided the final ″boost″) while still fairly close to Earth. During the explosion, how did the velocity of each of the two pieces of the system change? How did the velocity of the center of mass of the system change?

Determine the Concept The spacecraft speed increased toward the moon. The speed of the third-stage booster decreased, but the booster continued to move away from Earth and toward the moon. Right after the explosion, the center of

mass velocity was the same as before. After a while, however, the backward pull of gravity of Earth will cause it to decrease because the speeds of both the lunar ship and the booster decrease.

25 •• You throw a boomerang and for a while it "flies" horizontally in a straight line at a constant speed, while spinning rapidly. Draw a series of pictures, as viewed vertically down from overhead, of the boomerang in different rotational positions as it moves parallel to the surface of Earth. On each picture, indicate the location of the boomerang's center of mass and connect the dots to trace the trajectory of its center of mass. What is the center of mass's acceleration during this part of the flight?

Determine the Concept The diagram shows a spinning boomerang with its center of mass at the location of the circle. As viewed from above, the center of mass moves in a straight line as the boomerang spins about it. The acceleration of the center of mass is zero.

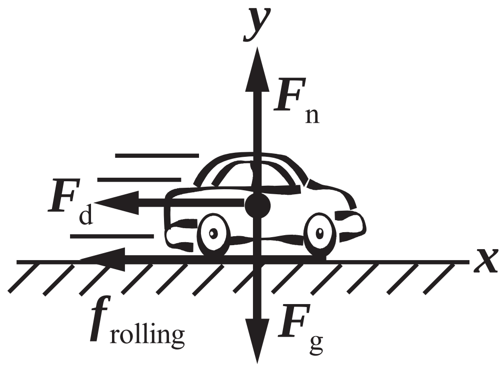


Estimation and Approximation

26 •• To determine the aerodynamic drag on a car, automotive engineers often use the "coast-down" method. The car is driven on a long, flat road at some convenient speed (60 mi/h is typical), shifted into neutral, and allowed to coast to a stop. The time that it takes for the speed to drop by successive 5-mi/h intervals is measured and used to compute the net force slowing the car down. (*a*) One day, a group measured that a Toyota Tercel with a mass of 1020 kg coasted down from 60.0 mi/h to 55.0 mi/h in 3.92 s. Estimate the average net force slowing the car down in this speed range. (*b*) If the coefficient of rolling friction for this car is known to be 0.020, what is the force of rolling friction that is acting to slow it down? Assuming that the only two forces acting on the car are rolling friction and aerodynamic drag, what is the average drag force acting on the car? (*c*) The drag force has the form $\frac{1}{2}C\rho Av^2$, where A is the cross-sectional area of the car facing into the air, v is the car's speed, ρ is the density of air, and C is a dimensionless constant of order 1. If the cross-sectional area of the car is 1.91 m^2, determine C from the data given. (The density of air is 1.21 kg/m^3; use 57.5 mi/h for the speed of the car in this computation.)

Picture the Problem The forces acting on the Tercel as it slows from 60 to 55 mi/h are a rolling-friction force exerted by the roadway, an air-drag force exerted by the air, the normal force exerted by the roadway, and the gravitational force exerted by Earth. The car is moving in the positive x direction. We can use Newton's second law to calculate the average force from the rate at which the

car's speed decreases and the rolling force from its definition. The drag force can be inferred from the average- and rolling-friction forces and the drag coefficient from the defining equation for the drag force.



(*a*) Apply $\sum F_x = ma_x$ to the car to relate the average force acting on it to its average acceleration:

$$F_{av} = ma_{av} = m\frac{\Delta v}{\Delta t}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = (1020\,\text{kg})\frac{5\dfrac{\text{mi}}{\text{h}}\times 1.609\dfrac{\text{km}}{\text{mi}}\times\dfrac{1\,\text{h}}{3600\,\text{s}}\times\dfrac{1000\,\text{m}}{\text{km}}}{3.92\,\text{s}} = 581\,\text{N} = \boxed{0.58\,\text{kN}}$$

(*b*) The rolling-friction force is the product of the coefficient of rolling friction and the normal force:

$$f_{rolling} = \mu_{rolling}F_n = \mu_{rolling}mg$$

Substitute numerical values and evaluate $f_{rolling}$:

$$f_{rolling} = (0.020)(1020\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{0.20\,\text{kN}}$$

Assuming that only two forces are acting on the car opposite to the direction of its motion gives:

$$F_{av} = F_d + f_{rolling} \Rightarrow F_d = F_{av} - f_{rolling}$$

Substitute numerical values and evaluate F_d:

$$F_d = 581\,\text{N} - 200\,\text{N} = \boxed{0.38\,\text{kN}}$$

(*c*) Using the definition of the drag force and its calculated value from (*b*) and the average speed of the car during this 5 mph interval, solve for C:

$$F_d = \tfrac{1}{2}C\rho Av^2 \Rightarrow C = \frac{2F_d}{\rho Av^2}$$

Substitute numerical values and evaluate C:

$$C = \frac{2(381\,\text{N})}{(1.21\,\text{kg/m}^3)(1.91\,\text{m}^2)\left(57.5\frac{\text{mi}}{\text{h}}\times\frac{1.609\,\text{km}}{\text{mi}}\times\frac{1\,\text{h}}{3600\,\text{s}}\times\frac{10^3\,\text{m}}{\text{km}}\right)^2} = \boxed{0.50}$$

27 •• [SSM] Using dimensional analysis, determine the units and dimensions of the constant b in the retarding force bv^n if (*a*) $n = 1$ and (*b*) $n = 2$. (*c*) Newton showed that the air resistance of a falling object with a circular cross section should be approximately $\frac{1}{2}\rho\pi r^2 v^2$, where $\rho = 1.20$ kg/m^3, the density of air. Show that this is consistent with your dimensional analysis for Part (*b*). (*d*) Find the terminal speed for a 56.0-kg skydiver; approximate his cross-sectional area as a disk of radius 0.30 m. The density of air near the surface of Earth is 1.20 kg/m^3. (*e*) The density of the atmosphere decreases with height above the surface of Earth; at a height of 8.0 km, the density is only 0.514 kg/m^3. What is the terminal velocity at this height?

Picture the Problem We can use the dimensions of force and speed to determine the dimensions of the constant b and the dimensions of ρ, r, and v to show that, for $n = 2$, Newton's expression is consistent dimensionally with our result from part (*b*). In Parts (*d*) and (*e*), we can apply Newton's second law under terminal speed conditions to find the terminal speed of the sky diver near the surface of Earth and at a height of 8 km. Assume that $g = 9.81$ m/s^2 remains constant. (Note: At 8 km, $g = 9.78$ m/s^2. However, it will not affect the result in Part (*e*).)

(*a*) Solve the drag force equation for b with $n = 1$:

$$b = \frac{F_\text{d}}{v}$$

Substitute the dimensions of F_d and v and simplify to obtain:

$$[b] = \frac{\frac{\text{ML}}{\text{T}^2}}{\frac{\text{L}}{\text{T}}} = \boxed{\frac{\text{M}}{\text{T}}}$$

and the units of b are $\boxed{\text{kg/s}}$

(*b*) Solve the drag force equation for b with $n = 2$:

$$b = \frac{F_\text{d}}{v^2}$$

Substitute the dimensions of F_d and v and simplify to obtain:

$$[b] = \frac{\frac{\text{ML}}{\text{T}^2}}{\left(\frac{\text{L}}{\text{T}}\right)^2} = \boxed{\frac{\text{M}}{\text{L}}}$$

and the units of b are $\boxed{\text{kg/m}}$

(*c*) Express the dimensions of Newton's expression:

$$[F_d] = \left[\tfrac{1}{2}\rho\pi r^2 v^2\right] = \left(\frac{\text{M}}{\text{L}^3}\right)(\text{L})^2\left(\frac{\text{L}}{\text{T}}\right)^2 = \boxed{\frac{\text{ML}}{\text{T}^2}}$$

From Part (*b*) we have:

$$[F_d] = \left[bv^2\right] = \left(\frac{\text{M}}{\text{L}}\right)\left(\frac{\text{L}}{\text{T}}\right)^2 = \boxed{\frac{\text{ML}}{\text{T}^2}}$$

(*d*) Letting the downward direction be the $+y$ direction, apply $\sum F_y = ma_y$ to the sky diver:

$$mg - \tfrac{1}{2}\rho\pi r^2 v_t^2 = 0 \Rightarrow v_t = \sqrt{\frac{2mg}{\rho\pi r^2}}$$

Substitute numerical values and evaluate v_t:

$$v_t = \sqrt{\frac{2(56\,\text{kg})(9.81\,\text{m/s}^2)}{\pi(1.2\,\text{kg/m}^3)(0.30\,\text{m})^2}} = \boxed{57\,\text{m/s}}$$

(*e*) Evaluate v_t at a height of 8 km:

$$v_t = \sqrt{\frac{2(56\,\text{kg})(9.81\,\text{m/s}^2)}{\pi(0.514\,\text{kg/m}^3)(0.30\,\text{m})^2}} = \boxed{87\,\text{m/s}}$$

28 •• Estimate the terminal velocity of an average sized raindrop and a golf-ball- sized hailstone. (*Hint*: See Problems 26 and 27.)

Picture the Problem From Newton's second law, the equation describing the motion of falling raindrops and large hailstones is $mg - F_d = ma$ where $F_d = \frac{1}{2}\rho\pi r^2 v^2 = bv^2$ is the drag force. Under terminal speed conditions ($a = 0$), the drag force is equal to the weight of the falling object. Take the radius of a raindrop to be 0.50 mm and the radius of a golf-ball sized hailstone to be 2.0 cm.

Express the relationship between v_t and the weight of a falling object under terminal speed:

$$bv_t^2 = mg \Rightarrow v_t = \sqrt{\frac{mg}{b}} \qquad (1)$$

Using $b = \frac{1}{2}\pi\rho r^2$, evaluate b_r:

$$b_r = \tfrac{1}{2}\pi(1.2\,\text{kg/m}^3)(0.50\times10^{-3}\,\text{m})^2 = 4.71\times10^{-7}\,\text{kg/m}$$

Evaluating b_h yields:

$$b_h = \tfrac{1}{2}\pi(1.2\,\text{kg/m}^3)(2.0\times10^{-2}\,\text{m})^2 = 7.54\times10^{-4}\,\text{kg/m}$$

Express the mass of a sphere in terms of its volume and density:

$$m = \rho V = \frac{4\pi r^3 \rho}{3}$$

Using $\rho_r = 1.0 \times 10^3$ kg/m^3, evaluate m_r:

$$m_r = \frac{4\pi\left(0.50\times10^{-3}\ \text{m}\right)^3\left(1.0\times10^3\ \text{kg/m}^3\right)}{3} = 5.24\times10^{-7}\ \text{kg}$$

Using $\rho_h = 920$ kg/m^3, evaluate m_h:

$$m_h = \frac{4\pi\left(2.0\times10^{-2}\ \text{m}\right)^3\left(920\,\text{kg/m}^3\right)}{3} = 3.08\times10^{-2}\ \text{kg}$$

Substitute numerical values in equation (1) and evaluate $v_{t,r}$:

$$v_{t,r} = \sqrt{\frac{\left(5.24\times10^{-7}\ \text{kg}\right)\left(9.81\,\text{m/s}^2\right)}{4.71\times10^{-7}\ \text{kg/m}}} = \boxed{3.3\,\text{m/s}}$$

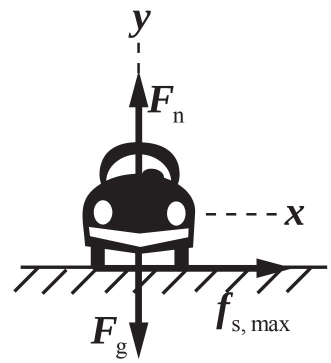
Substitute numerical values in equation (1) and evaluate $v_{t,h}$:

$$v_{t,h} = \sqrt{\frac{\left(3.08\times10^{-2}\ \text{kg}\right)\left(9.81\,\text{m/s}^2\right)}{7.54\times10^{-4}\ \text{kg/m}}} = \boxed{20\,\text{m/s}}$$

29 •• Estimate the minimum coefficient of static friction needed between a car's tires and the pavement in order to complete a left turn at a city street intersection at the posted straight-ahead speed limit of 25 mph and on narrow inner-city streets. Comment on the wisdom of attempting such a turn at that speed.

Picture the Problem In order to perform this estimate, we need to determine a rough radius of curvature for the car's turn in a normal city intersection. Assuming the car goes from right-hand lane to right-hand lane, and assuming fairly normal dimensions of 40 feet for the width of the street, the center of the car's path travels along a circle of, say, 30 feet in radius. The net centripetal force is provided by the force of static friction and the acceleration of the car is equal to this net force divided by the mass of the car. Finally, we solve for the coefficient of static friction.

A diagram showing the forces acting on the car as it rounds the curve is shown to the right.



Apply $\sum F_x = ma_x$ to the car's tires:

$$f_{s,\,max} = ma_x = m\frac{v^2}{r}$$

or, because $f_{s,\,max} = \mu_s F_n$

$$\mu_s F_n = m\frac{v^2}{r} \Rightarrow \mu_s = \frac{mv^2}{rF_n} \quad (1)$$

Apply $\sum F_y = ma_y$ to the car's tires:

$$F_n - F_g = 0$$

or, because $F_g = mg$,

$$F_n - mg = 0 \Rightarrow F_n = mg$$

Substituting for F_n in equation (1) yields:

$$\mu_s = \frac{mv^2}{rmg} = \frac{v^2}{rg}$$

Substitute numerical values and evaluate μ_s:

$$\mu_s = \frac{\left(25\,\frac{\text{mi}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}} \times \frac{1609\,\text{m}}{\text{mi}}\right)^2}{\left(30\,\text{ft} \times 0.3048\,\frac{\text{m}}{\text{ft}}\right)\left(9.81\,\text{m/s}^2\right)}$$

$$= \boxed{1.4}$$

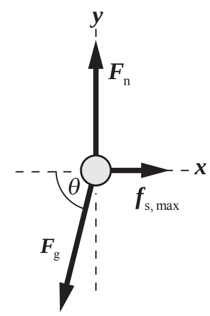
This is probably not such a good idea. Tires on asphalt or concrete have a maximum coefficient of static friction of about 1.

30 •• Estimate the widest stance you can take when standing on a dry, icy surface. That is, how wide can you safely place your feet and not slip into an undesired "split?" Let the coefficient of static friction of rubber on ice be roughly 0.25.

Picture the Problem We need to estimate the forces active at the place of each foot. Assuming a symmetrical stance, with the defining angle being the angle between each leg and the ground, θ, we can then draw a force diagram and apply Newton's second law to your foot. The free-body diagram shows the normal

force, exerted by the icy surface, the maximum static friction force, also exerted by the icy surface, and the force due to gravity exerted on your foot.

A free-body diagram showing the forces acting on one foot is shown to the right.



Apply $\sum \vec{F} = m\vec{a}$ to one of your feet:

$$\sum F_x = f_{s,max} - F_g \cos\theta = 0 \qquad (1)$$

and

$$\sum F_y = F_n - F_g \sin\theta = 0 \qquad (2)$$

Substituting $f_{s,\,max} = \mu_s F_n$ in equation (1) gives:

$$\mu_s F_n - F_g \cos\theta = 0$$

or

$$\mu_s F_n = F_g \cos\theta \qquad (3)$$

Solving equation (2) for F_n yields:

$$F_n = F_g \sin\theta \qquad (4)$$

Divide equation (4) by equation (3) to obtain:

$$\tan\theta = \frac{1}{\mu_s} \Rightarrow \theta = \tan^{-1}\left(\frac{1}{\mu_s}\right)$$

Substitute the numerical value of μ_s and evaluate θ:

$$\theta = \tan^{-1}\left(\frac{1}{0.25}\right) = 76°$$

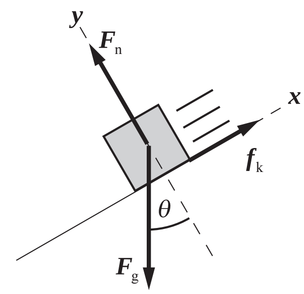
This angle corresponds to an angle between your legs of about 28°.

Friction

31 • [SSM] A block of mass m slides at constant speed down a plane inclined at an angle of θ with the horizontal. It follows that (*a*) $\mu_k = mg \sin\theta$, (*b*) $\mu_k = \tan\theta$, (*c*) $\mu_k = 1 - \cos\theta$, (*d*) $\mu_k = \cos\theta - \sin\theta$.

Picture the Problem The block is in equilibrium under the influence of $\vec{F}_n$, $m\vec{g}$, and $\vec{f}_k$; that is, $\vec{F}_n + m\vec{g} + \vec{f}_k = 0$. We can apply Newton's second law to determine the relationship between f_k, θ, and mg.

A pictorial representation showing the forces acting on the sliding block is shown to the right.



Using its definition, express the coefficient of kinetic friction:

$$\mu_k = \frac{f_k}{F_n} \quad (1)$$

Apply $\sum F_x = ma_x$ to the block:

$$f_k - mg\sin\theta = ma_x$$

or, because $a_x = 0$,

$$f_k = mg\sin\theta$$

Apply $\sum F_y = ma_y$ to the block:

$$F_n - mg\cos\theta = ma_y$$

or, because $a_y = 0$,

$$F_n = mg\cos\theta$$

Substitute for f_k and F_n in equation (1) and simplify to obtain:

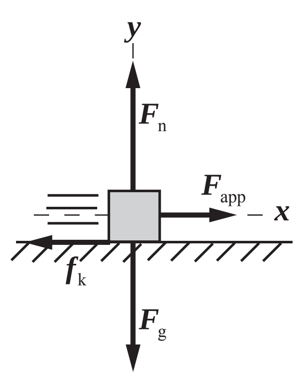
$$\mu_k = \frac{mg\sin\theta}{mg\cos\theta} = \tan\theta$$

and $\boxed{(b)}$ is correct.

32 • A block of wood is pulled at constant velocity by a horizontal string across a horizontal surface with a force of 20 N. The coefficient of kinetic friction between the surfaces is 0.3. The force of friction is (*a*) impossible to determine without knowing the mass of the block, (*b*) impossible to determine without knowing the speed of the block, (*c*) 0.30 N, (*d*) 6.0 N, or (*e*) 20 N.

Picture the Problem The block is in equilibrium under the influence of $\vec{F}_n$, $\vec{F}_g$, $\vec{F}_{app}$, and $\vec{f}_k$; that is

$$\vec{F}_n + \vec{F}_g + \vec{F}_{app} + \vec{f}_k = 0$$



We can apply Newton's second law to determine f_k.

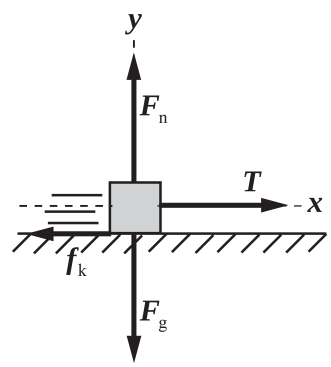
Apply $\sum F_x = ma_x$ to the block: $F_{\text{app}} - f_{\text{k}} = ma_x$

or, because $a_x = 0$,

$f_{\text{k}} = F_{\text{app}} = 20\ \text{N}$ and $\boxed{(e)}$ is correct.

33 • **[SSM]** A block weighing 20-N rests on a horizontal surface. The coefficients of static and kinetic friction between the surface and the block are $\mu_s = 0.80$ and $\mu_k = 0.60$. A horizontal string is then attached to the block and a constant tension T is maintained in the string. What is the subsequent force of friction acting on the block if (*a*) $T = 15$ N or (*b*) $T = 20$ N?

Picture the Problem Whether the friction force is that due to static friction or kinetic friction depends on whether the applied tension is greater than the maximum static friction force. We can apply the definition of the maximum static friction to decide whether $f_{\text{s,max}}$ or T is greater.



Noting that $F_{\text{n}} = F_{\text{g}}$, calculate the maximum static friction force:

$$f_{\text{s,max}} = \mu_{\text{s}} F_{\text{n}} = \mu_{\text{s}} F_{\text{g}} = (0.80)(20\ \text{N}) = 16\ \text{N}$$

(*a*) Because $f_{\text{s,max}} > T$:

$$f = f_{\text{s}} = T = \boxed{15\ \text{N}}$$

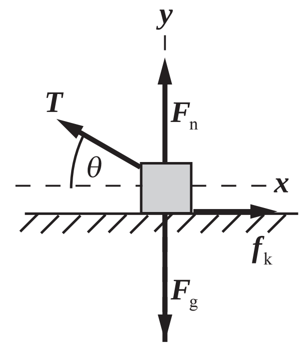
(*b*) Because $T > f_{\text{s,max}}$:

$$f = f_{\text{k}} = \mu_{\text{k}} F_{\text{n}} = \mu_{\text{k}} F_{\text{g}} = (0.60)(20\ \text{N}) = \boxed{12\ \text{N}}$$

34 • A block of mass m is pulled at a constant velocity across a horizontal surface by a string as shown in Figure 5-60. The magnitude of the frictional force is (*a*) $\mu_k mg$, (*b*) $T\cos\theta$, (*c*) $\mu_k(T - mg)$, (*d*) $\mu_k T\sin\theta$, or (*e*) $\mu_k(mg - T\sin\theta)$.

Picture the Problem The block is in equilibrium under the influence of the forces $\vec{T}$, $\vec{f}_{\text{k}}$, $\vec{F}_n$, and $\vec{F}_g$; that is $\vec{T} + \vec{f}_{\text{k}} + \vec{F}_g + \vec{F}_n = 0$. We can apply Newton's second law to determine the relationship between T and f_{k}.

A free-body diagram showing the forces acting on the block is shown to the right.

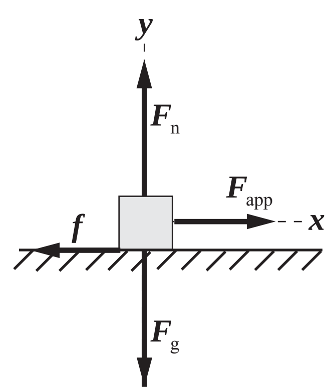


Apply $\sum F_x = ma_x$ to the block: $-T\cos\theta + f_k = ma_x$

Because $a_x = 0$: $f_k = T\cos\theta$ and $\boxed{(b)}$ is correct.

35 • **[SSM]** A 100-kg crate rests on a thick-pile carpet. A weary worker then pushes on the crate with a horizontal force of 500 N. The coefficients of static and kinetic friction between the crate and the carpet are 0.600 and 0.400, respectively. Find the subsequent frictional force exerted by the carpet on the crate.

Picture the Problem Whether the friction force is that due to static friction or kinetic friction depends on whether the applied tension is greater than the maximum static friction force. If it is, then the box moves and the friction force is the force of kinetic friction. If it is less, the box does not move.



The maximum static friction force is given by:

$$f_{s,max} = \mu_s F_n$$

or, because $F_n = F_g = mg$,

$$f_{s,max} = \mu_s mg$$

Substitute numerical values and evaluate $f_{s,max}$:

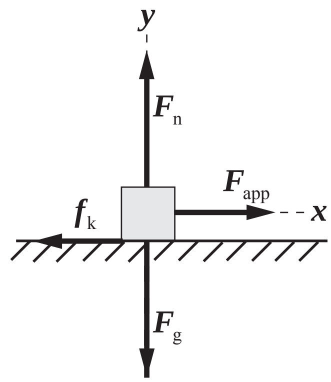
$$f_{s,max} = (0.600)(100\,\text{kg})(9.81\,\text{m/s}^2) = 589\,\text{N}$$

Because $f_{s,\,max} > F_{app}$, the box does not move and :

$$F_{app} = f_s = \boxed{500\,\text{N}}$$

36 • A box weighing 600 N is pushed along a horizontal floor at constant velocity with a force of 250 N parallel to the floor. What is the coefficient of kinetic friction between the box and the floor?

Picture the Problem Because the box is moving with constant velocity, its acceleration is zero and it is in equilibrium under the influence of $\vec{F}_{\text{app}}$, $\vec{F}_{\text{n}}$, $\vec{F}_{\text{g}}$, and $\vec{f}_{\text{k}}$; that is, $\vec{F}_{\text{app}} + \vec{F}_{\text{n}} + \vec{F}_{\text{g}} + \vec{f}_{\text{k}} = 0$. We can apply Newton's second law to determine the relationship between f_{k} and mg.



The definition of μ_{k} is:

$$\mu_{\text{k}} = \frac{f_{\text{k}}}{F_{\text{n}}} \qquad (1)$$

Apply $\sum F_y = ma_y$ to the box:

$$F_{\text{n}} - F_{\text{g}} = ma_y$$

or, because $a_y = 0$,

$$F_{\text{n}} - F_{\text{g}} = 0 \Rightarrow F_{\text{n}} = F_{\text{g}} = mg = 600\text{ N}$$

Apply $\sum F_x = ma_x$ to the box:

$$F_{\text{app}} - f_{\text{k}} = ma_x$$

or, because $a_x = 0$,

$$F_{\text{app}} = f_{\text{k}} = 250\text{ N}$$

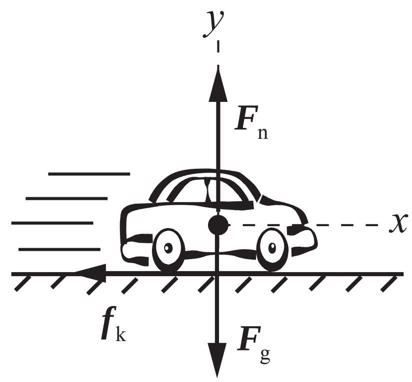
Substitute numerical values in equation (1) and evaluate μ_{k}:

$$\mu_{\text{k}} = \frac{250\text{ N}}{600\text{ N}} = \boxed{0.417}$$

37 • **[SSM]** The coefficient of static friction between the tires of a car and a horizontal road is 0.60. Neglecting air resistance and rolling friction, (*a*) what is the magnitude of the maximum acceleration of the car when it is braked? (*b*) What is the shortest distance in which the car can stop if it is initially traveling at 30 m/s?

Picture the Problem Assume that the car is traveling to the right and let the positive x direction also be to the right. We can use Newton's second law of motion and the definition of μ_{s} to determine the maximum acceleration of the car. Once we know the car's maximum acceleration, we can use a constant-acceleration equation to determine the least stopping distance.

(*a*) A diagram showing the forces acting on the car is shown to the right.



Apply $\sum F_x = ma_x$ to the car: $\quad -f_{s,max} = -\mu_s F_n = ma_x \qquad (1)$

Apply $\sum F_y = ma_y$ to the car and solve for F_n:

$$F_n - F_g = ma_y$$

$$F_n - w = ma_y = 0$$

or, because $a_y = 0$ and $F_g = mg$,

$$F_n = mg \qquad (2)$$

Substitute for Fn in equation (1) to obtain:

$$-f_{s,max} = -\mu_s mg = ma_x$$

Solving for $a_{x,max}$ yields:

$$a_{x,max} = \mu_s g$$

Substitute numerical values and evaluate $a_{x,max}$:

$$a_{x,max} = (0.60)(9.81\ \text{m/s}^2) = 5.89\ \text{m/s}^2 = \boxed{5.9\ \text{m/s}^2}$$

(b) Using a constant-acceleration equation, relate the stopping distance of the car to its initial speed and its acceleration:

$$v_x^2 = v_{0x}^2 + 2a_x\Delta x$$

or, because $v_x = 0$,

$$0 = v_{0x}^2 + 2a_x\Delta x \Rightarrow \Delta x = \frac{-v_{0x}^2}{2a_x}$$

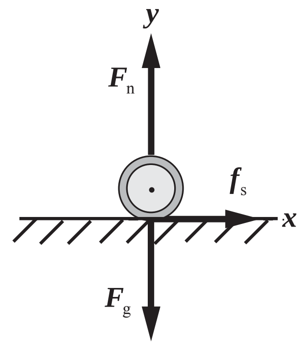
Using ax = −5.89 m/s2 because the acceleration of the car is to the left, substitute numerical values and evaluate Δx:

$$\Delta x = \frac{-(30\ \text{m/s})^2}{2(-5.89\ \text{m/s}^2)} = \boxed{76\ \text{m}}$$

38 • The force that accelerates a car along a flat road is the frictional force exerted by the road on the car's tires. (*a*) Explain why the acceleration can be greater when the wheels do not slip. (*b*) If a car is to accelerate from 0 to 90 km/h in 12 s, what is the minimum coefficient of friction needed between the road and tires? Assume that the drive wheels support exactly half the weight of the car.

Picture the Problem We can use the definition of acceleration and apply Newton's second law to the horizontal and vertical components of the forces to determine the minimum coefficient of friction between the road and the tires.

(*a*) The free-body diagram shows the forces acting on the tires on the drive wheels, the tires we're assuming support half the weight of the car.



Because $\mu_s > \mu_k$, f will be greater if the wheels do not slip.

(*b*) Apply $\sum F_x = ma_x$ to the car: $f_s = \mu_s F_n = ma_x$ (1)

Apply $\sum F_y = ma_y$ to the car and solve for F_n: $F_n - F_g = ma_y$
or, because $a_y = 0$ and $F_g = \frac{1}{2}mg$,
$F_n = \frac{1}{2}mg$

Substituting for F_n in equation (1) yields: $\frac{1}{2}\mu_s mg = ma_x \Rightarrow \mu_s = \frac{2a_x}{g}$

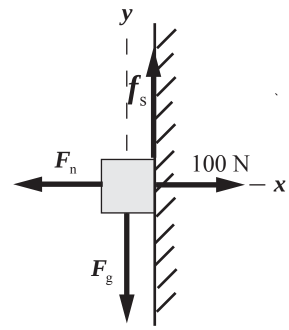
Substitute for a_x to obtain: $\mu_s = \frac{2\Delta v}{g\Delta t}$

Substitute numerical values and evaluate μ_s:

$$\mu_s = \frac{2\left(90\,\frac{\text{km}}{\text{h}} \times \frac{10^3\ \text{m}}{\text{km}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)}{\left(9.81\,\frac{\text{m}}{\text{s}^2}\right)(12\,\text{s})} = \boxed{0.42}$$

39 •• A 5.00-kg block is held at rest against a vertical wall by a horizontal force of 100 N. (*a*) What is the frictional force exerted by the wall on the block? (*b*) What is the minimum horizontal force needed to prevent the block from falling if the static coefficient of friction between the wall and the block is 0.400?

Picture the Problem The block is in equilibrium under the influence of the forces shown on the force diagram. We can use Newton's second law and the definition of μ_s to solve for f_s and F_n.



(*a*) Apply $\sum F_y = ma_y$ to the block:

$f_s - mg = ma_y$

or, because $a_y = 0$,

$f_s - mg = 0 \Rightarrow f_s = mg$

Substitute numerical values and evaluate f_s :

$$f_s = (5.00\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{49.1\,\text{N}}$$

(*b*) Use the definition of μ_s to express F_n:

$$F_n = \frac{f_{s,\max}}{\mu_s}$$

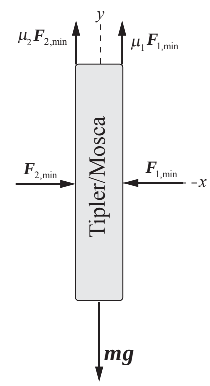
Substitute numerical values and evaluate F_n:

$$F_n = \frac{49.1\,\text{N}}{0.400} = \boxed{123\,\text{N}}$$

40 •• A tired and overloaded student is attempting to hold a large physics textbook wedged under his arm, as shown in Figure 5-61. The textbook has a mass of 3.2 kg, while the coefficient of static friction of the textbook against the student's underarm is 0.320 and the coefficient of static friction of the book against the student's shirt is 0.160. (*a*) What is the minimum horizontal force that the student must apply to the textbook to prevent it from falling? (*b*) If the student can only exert a force of 61 N, what is the acceleration of the textbook as it slides from under his arm? The coefficient of kinetic friction of arm against textbook is 0.200, while that of shirt against textbook is 0.090.

Picture the Problem We can apply Newton's second law to relate the minimum force required to hold the book in place to its mass and to the coefficients of static friction. In Part (*b*), we can proceed similarly to relate the acceleration of the book to the coefficients of kinetic friction.

(*a*) The force diagram shows the forces acting on the book. The normal force is the net force the student exerts in squeezing the book. Let the horizontal direction be the +*x* direction and upward the +*y* direction. Note that the normal force is the same on either side of the book because it is not accelerating in the horizontal direction. The book could be accelerating downward.



Apply $\sum \vec{F} = m\vec{a}$ to the book:

$$\sum F_x = F_{2,\min} - F_{1,\min} = 0$$

and

$$\sum F_y = \mu_{s,1} F_{1,\min} + \mu_{s,2} F_{2,\min} - mg = 0$$

Noting that $F_{1,\min} = F_{2,\min}$, solve the *y* equation for $F_{\min}$:

$$F_{\min} = \frac{mg}{\mu_{s,1} + \mu_{s,2}}$$

Substitute numerical values and evaluate $F_{\min}$:

$$F_{\min} = \frac{(3.2\,\text{kg})(9.81\,\text{m/s}^2)}{0.320 + 0.160} = \boxed{65\,\text{N}}$$

(*b*) Apply $\sum F_y = ma_y$ with the book accelerating downward, to obtain:

$$\sum F_y = \mu_{k,1} F + \mu_{k,2} F - mg = ma$$

Solving for a_y yields:

$$a_y = \frac{\mu_{k,1} + \mu_{k,2}}{m} F - g$$

Substitute numerical values and evaluate a_y:

$$a_y = \left| \left(\frac{0.200 + 0.090}{3.2\,\text{kg}} \right) (61\,\text{N}) - 9.81\,\text{m/s}^2 \right|$$

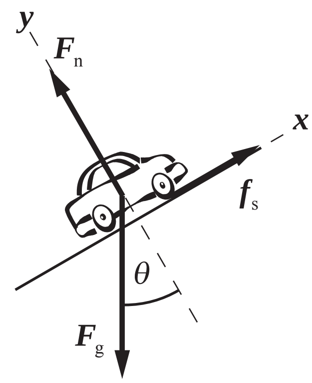
$$= \boxed{4.3\,\text{m/s}^2\text{, downward}}$$

41 •• You are racing in a rally on a snowy day when the temperature is near the freezing point. The coefficient of static friction between a car's tires and an icy road is 0.080. Your crew boss is concerned about some of the hills on the course and wants you to think about switching to studded tires. To address the issue, he wants to compare the actual hill angles on the course to see which of them your car can negotiate. (*a*) What is the angle of the steepest incline that a vehicle with four-wheel drive can climb at constant speed? (*b*) Given that the hills are icy, what is the steepest possible hill angle for the same four-wheel drive car to descend at constant speed?

Picture the Problem We can use the definition of the coefficient of static friction

and Newton's second law to relate the angle of the incline to the forces acting on the car.

(*a*) The free-body diagram shows the forces acting on the car when it is either moving up the hill or down the hill without acceleration. The friction force that the ground exerts on the tires is the force f_s shown acting up the incline.



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = f_s - F_g \sin\theta = 0 \qquad (1)$$

and

$$\sum F_y = F_n - F_g \cos\theta = 0 \qquad (2)$$

Because $F_g = mg$, equations (1) and (2) become:

$$f_s - mg\sin\theta = 0 \qquad (3)$$

and

$$F_n - mg\cos\theta = 0 \qquad (4)$$

Solving equation (3) for f_s and equation (4) for F_n yields:

$$f_s = mg\sin\theta$$

and

$$F_n = mg\cos\theta$$

Use the definition of μ_s to relate f_s and F_n:

$$\mu_s = \frac{f_s}{F_n} = \frac{mg\sin\theta}{mg\cos\theta} = \tan\theta$$

Solving for θ yields:

$$\theta = \tan^{-1}(\mu_s) = \tan^{-1}(0.080) = \boxed{4.6°}$$

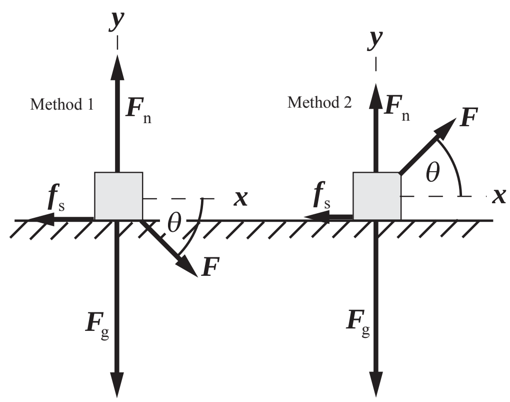
(*b*) Proceed exactly as in (*a*) to obtain:

$$\theta = \tan^{-1}(0.080) = \boxed{4.6°}$$

42 •• A 50-kg box that is resting on a level floor must be moved. The coefficient of static friction between the box and the floor is 0.60. One way to move the box is to push down on the box at an angle θ below the horizontal. Another method is to pull up on the box at an angle θ above the horizontal. (*a*) Explain why one method requires less force than the other. (*b*) Calculate the minimum force needed to move the box by each method if θ = 30º and compare the answer with the results when θ = 0°.

Picture the Problem The free-body

diagrams for the two methods are shown to the right. Method 1 results in the box being pushed into the floor, increasing the normal force and the static friction force. Method 2 partially lifts the box,, reducing the normal force and the static friction force. We can apply Newton's second law to obtain expressions that relate the maximum static friction force to the applied force $\vec{F}$.



(*a*) Method 2 is preferable because it reduces F_n and, therefore, f_s.

(*b*) Apply $\sum F_x = ma_x$ to the box:

$$F\cos\theta - f_x = F\cos\theta - \mu_s F_n = 0$$

Method 1: Apply $\sum F_y = ma_y$ to the block and solve for F_n:

$$F_n - mg - F\sin\theta = 0$$
and
$$F_n = mg + F\sin\theta$$

Relate $f_{s,max}$ to F_n:

$$f_{s,max} = \mu_s F_n = \mu_s(mg + F\sin\theta) \quad (1)$$

Method 2: Apply $\sum F_y = ma_y$ to the forces in the y direction and solve for F_n:

$$F_n - mg + F\sin\theta = 0$$
and
$$F_n = mg - F\sin\theta$$

Relate $f_{s,max}$ to F_n:

$$f_{s,max} = \mu_s F_n = \mu_s(mg - F\sin\theta) \quad (2)$$

Express the condition that must be satisfied to move the box by either method:

$$f_{s,max} = F\cos\theta \quad (3)$$

Method 1: Substitute (1) in (3) and solve for F:

$$F_1 = \frac{\mu_s mg}{\cos\theta - \mu_s \sin\theta} \quad (4)$$

Method 2: Substitute (2) in (3) and solve for F:

$$F_2 = \frac{\mu_s mg}{\cos\theta + \mu_s \sin\theta} \quad (5)$$

Substitute numerical values and evaluate equations (4) and (5) with $\theta = 30°$:

$$F_1(30°) = \frac{(0.60)(50\text{ kg})(9.81\text{ m/s}^2)}{\cos 30° - (0.60)\sin 30°} = \boxed{0.52\text{ kN}}$$

and

$$F_2(30°) = \frac{(0.60)(50\text{ kg})(9.81\text{ m/s}^2)}{\cos 30° + (0.60)\sin 30°} = \boxed{0.25\text{ kN}}$$

Evaluate equations (4) and (5) with $\theta = 0°$:

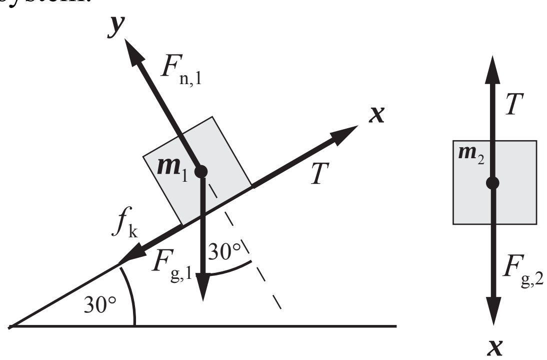
$$F_1(0°) = \frac{(0.60)(50\text{ kg})(9.81\text{ m/s}^2)}{\cos 0° - (0.60)\sin 0°} = \boxed{0.29\text{ kN}}$$

and

$$F_2(0°) = \frac{(0.60)(50\text{ kg})(9.81\text{ m/s}^2)}{\cos 0° + (0.60)\sin 0°} = \boxed{0.29\text{ kN}}$$

43 •• [SSM] A block of mass $m_1 = 250$ g is at rest on a plane that makes an angle of $\theta = 30°$ with the horizontal. The coefficient of kinetic friction between the block and the plane is 0.100. The block is attached to a second block of mass $m_2 = 200$ g that hangs freely by a string that passes over a frictionless, massless pulley (Figure 5-62). When the second block has fallen 30.0 cm, what will be its speed?

Picture the Problem Choose a coordinate system in which the $+x$ direction is up the incline for the block whose mass is m_1 and downward for the block whose mass is m_2. We can find the speed of the system when it has moved a given distance by using a constant-acceleration equation. We'll assume that the string is massless and that it does not stretch. Under the influence of the forces shown in the free-body diagrams, the blocks will have a common acceleration a. The application of Newton's second law to each block, followed by the elimination of the tension T and the use of the definition of f_k, will allow us to determine the acceleration of the system.



Using a constant-acceleration equation, relate the speed of the system to its acceleration and displacement:

$$v_x^2 = v_{0x}^2 + 2a_x\Delta x$$

and, because $v_{0x} = 0$,

$$v_x^2 = 2a_x\Delta x \Rightarrow v_x = \sqrt{2a_x\Delta x} \qquad (1)$$

Apply $\sum\vec{F} = m\vec{a}$ to the block whose mass is m_1:

$$\sum F_x = T - f_k - F_{g,1}\sin 30° = m_1 a_x \qquad (2)$$

and

$$\sum F_y = F_{n,1} - F_{g,1}\cos 30° = 0 \qquad (3)$$

Because $F_{g,1} = m_1 g$, equations (2) and (3) can be written as:

$$T - f_k - m_1 g\sin 30° = m_1 a_x \qquad (4)$$

and

$$F_{n,1} = m_1 g\cos 30° \qquad (5)$$

Using $f_k = \mu_k F_{n,1}$, substitute equation (5) in equation (4) to obtain:

$$T - \mu_k m_1 g\cos 30° - m_1 g\sin 30° = m_1 a_x \qquad (6)$$

Applying $\sum F_x = ma_x$ to the block whose mass is m_2 gives:

$$F_{g,2} - T = m_2 a_x$$

or, because $F_{g,2} = m_2 g$,

$$m_2 g - T = m_2 a_x \qquad (7)$$

Add equations (6) and (7) to eliminate T and then solve for a_x to obtain:

$$a_x = \frac{(m_2 - \mu_k m_1\cos 30° - m_1\sin 30°)g}{m_1 + m_2}$$

Substituting for a_x in equation (1) and simplifying yields:

$$v_x = \sqrt{\frac{2[m_2 - m_1(\mu_k\cos 30° + \sin 30°)]g\Delta x}{m_1 + m_2}}$$

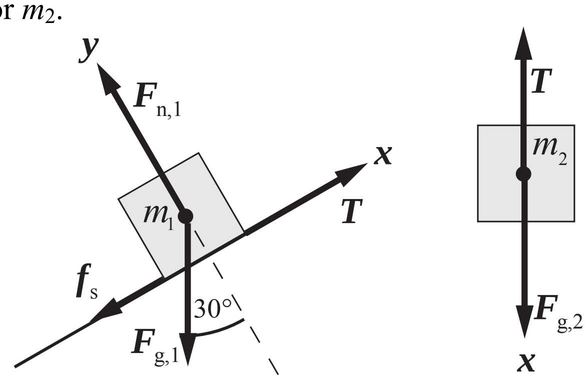
Substitute numerical values and evaluate v_x:

$$v_x = \sqrt{\frac{2[0.200\text{ kg} - (0.250\text{ kg})((0.100)\cos 30° + \sin 30°)](9.81\text{ m/s}^2)(0.300\text{ m})}{0.250\text{ kg} + 0.200\text{ kg}}}$$

$$= \boxed{84\text{ cm/s}}$$

44 •• In Figure 5-62 $m_1 = 4.0$ kg and the coefficient of static friction between the block and the incline is 0.40. (*a*) Find the range of possible values for m_2 for which the system will be in static equilibrium. (*b*) Find the frictional force on the 4.0-kg block if $m_2 = 1.0$ kg?

Picture the Problem Choose a coordinate system in which the +*x* direction is up the incline for the block whose mass is m_1 and downward for the block whose mass is m_2. We'll assume that the string is massless and that it does not stretch. Under the influence of the forces shown in the free-body diagrams, the blocks are in static equilibrium. While f_s can be either up or down the incline, the free-body diagram shows the situation in which motion is impending up the incline. The application of Newton's second law to each block, followed by the elimination of the tension T and the use of the definition of f_s, will allow us to determine the range of values for m_2.



(*a*) Noting that $F_{g,1} = m_1 g$, apply $\sum \vec{F} = m\vec{a}$ to the block whose mass is m_1:

$$\sum F_x = T \pm f_{s,max} - m_1 g \sin 30° = 0 \quad (1)$$

and

$$\sum F_y = F_{n,1} - m_1 g \cos 30° = 0 \quad (2)$$

Using $f_{s,\,max} = \mu_s F_n$, substitute equation (2) in equation (1) to obtain:

$$T \pm \mu_s m_1 g \cos 30° - m_1 g \sin 30° = 0 \quad (3)$$

Noting that $F_{g,2} = m_2 g$, apply $\sum F_x = m a_x$ to the block whose mass is m_2:

$$m_2 g - T = 0 \quad (4)$$

Add equations (3) and (4) to eliminate T and solve for m_2:

$$m_2 = m_1(\pm\mu_s\cos 30° + \sin 30°) \quad (5)$$

Substitute numerical values to obtain:

$$m_2 = (4.0\,\text{kg})[\pm(0.40)\cos 30° + \sin 30°]$$

Denoting the value of m_2 with a plus sign as $m_{2,+}$ and the value of m_2 with the minus sign as $m_{2,-}$ determine the range of values of m_2 for which the system is in static equilibrium:

$m_{2,+} = 3.4\,\text{kg}$ and $m_{2,-} = 0.61\,\text{kg}$

and

$$\boxed{0.61\,\text{kg} \le m_2 \le 3.4\,\text{kg}}$$

(*b*) With m_2 = 1 kg, the impending motion is down the incline and the static friction force is up the incline. Apply $\sum F_x = ma_x$ to the block whose mass is m_1:

$$T + f_s - m_1 g\sin 30° = 0 \quad (6)$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$$m_2 g - T = 0 \quad (7)$$

Add equations (6) and (7) and solve for f_s to obtain:

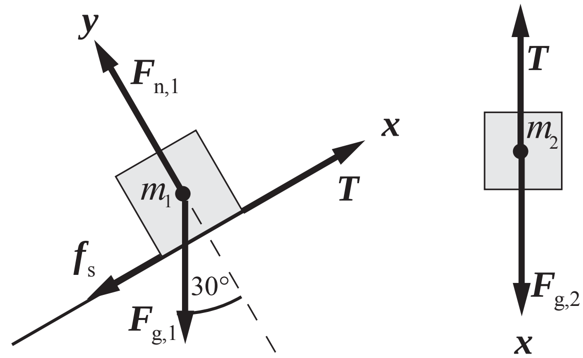
$$f_s = (m_1\sin 30° - m_2)g$$

Substitute numerical values and evaluate f_s:

$$f_s = [(4.0\,\text{kg})\sin 30° - 1.0\,\text{kg}](9.81\,\text{m/s}^2) = \boxed{9.8\,\text{N}}$$

45 •• In Figure 5-62, m_1 = 4.0 kg, m_2 = 5.0 kg, and the coefficient of kinetic friction between the inclined plane and the 4.0-kg block is μ_k = 0.24. Find the magnitude of the acceleration of the masses and the tension in the cord.

Picture the Problem Choose a coordinate system in which the +x direction is up the incline for the block whose mass is m_1 and downward for the block whose mass is m_2. We'll assume that the string is massless and that it does not stretch. Under the influence of the forces shown in the free-body diagrams, the blocks will have a common acceleration a. The application of Newton's second law to each block, followed by the elimination of the tension T and the use of the definition of f_k, will allow us to determine the acceleration of the system. Finally, we can substitute for the tension in either of the motion equations to determine the acceleration of the masses.



Noting that $F_{g,1} = m_1 g$, apply $\sum \vec{F} = m\vec{a}$ to the block whose mass is m_1:

$$\sum F_x = T - f_k - m_1 g \sin 30° = m_1 a_x \quad (1)$$

and

$$\sum F_y = F_{n,1} - m_1 g \cos 30° = 0 \quad (2)$$

Using $f_k = \mu_k F_n$, substitute equation (2) in equation (1) to obtain:

$$T - \mu_k m_1 g \cos 30° - m_1 g \sin 30° = m_1 a_x \quad (3)$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$$m_2 g - T = m_2 a_x \quad (4)$$

Add equations (3) and (4) to eliminate T and solve for a_x to obtain:

$$a_x = \frac{(m_2 - \mu_k m_1 \cos 30° - m_1 \sin 30°)g}{m_1 + m_2}$$

Substituting numerical values and evaluating a_x yields:

$$a_x = \frac{[5.0\text{ kg} - (0.24)(4.0\text{ kg})\cos 30° - (4.0\text{ kg})\sin 30°](9.81\text{ m/s}^2)}{4.0\text{ kg} + 5.0\text{ kg}} = \boxed{2.4\text{ m/s}^2}$$

Solving equation (3) for T yields:

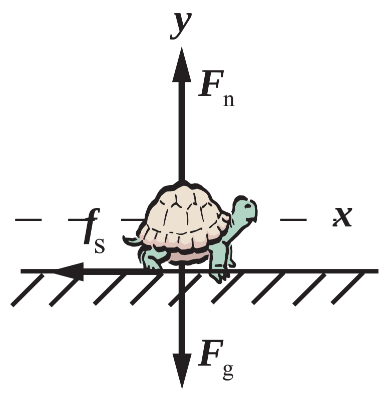
$$T = m_1 a_x + [\mu_k \cos 30° + \sin 30°]m_1 g$$

Substitute numerical values and evaluate T:

$$T = (4.0\text{ kg})(2.36\text{ m/s}^2) + [(0.24)\cos 30° + \sin 30°](4.0\text{ kg})(9.81\text{ m/s}^2) = \boxed{37\text{ N}}$$

46 •• A 12-kg turtle rests on the bed of a zookeeper's truck, which is traveling down a country road at 55 mi/h. The zookeeper spots a deer in the road, and slows to a stop in 12 s. Assuming constant acceleration, what is the minimum coefficient of static friction between the turtle and the truck bed surface that is needed to prevent the turtle from sliding?

Picture the Problem We can determine the acceleration necessary for the truck and turtle by considering the displacement of both during the given time interval. The static friction force must provide the necessary acceleration for the turtle. The turtle, if it is not to slip, must have this acceleration which is produced by the static friction force acting on it



The required coefficient of static friction is given by:

$$\mu_s = \frac{f_s}{F_n} \qquad (1)$$

Letting m represent the mass of the turtle, apply $\sum \vec{F} = m\vec{a}$ to the turtle:

$$\sum F_x = -f_s = ma_x \qquad (2)$$

and

$$\sum F_y = F_n - F_g = ma_y \qquad (3)$$

Solving equation (2) for f_s yields:

$$f_s = -ma_x$$

Because $a_y = 0$ and $F_g = mg$, equation (3) becomes:

$$F_n = F_g = mg$$

Substituting for f_s and F_n in equation (1) and simplifying yields:

$$\mu_s = \frac{-ma_x}{mg} = \frac{-a_x}{g} \qquad (4)$$

The acceleration of the truck and turtle is given by:

$$a_x = \frac{\Delta v}{\Delta t} = \frac{v_{f,x} - v_{i,x}}{\Delta t}$$

or, because $v_{f,x} = 0$,

$$a_x = \frac{-v_{i,x}}{\Delta t}$$

Substitute for a_x in equation (4) to obtain:

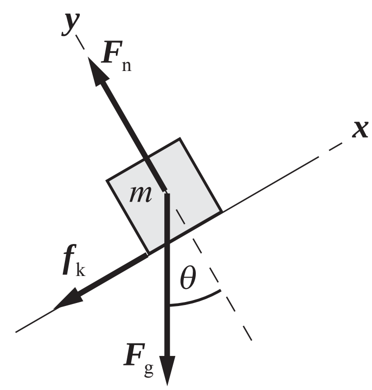
$$\mu_s = \frac{v_{i,x}}{g\Delta t}$$

Substitute numerical values and evaluate μ_s:

$$\mu_s = \frac{55\,\frac{\text{mi}}{\text{h}} \times \frac{1609\text{ m}}{\text{mi}} \times \frac{1\text{ h}}{3600\text{ s}}}{\left(9.81\text{ m/s}^2\right)\left(12\text{ s}\right)} = \boxed{0.21}$$

47 •• [SSM] A 150-g block is projected up a ramp with an initial speed of 7.0 m/s. The coefficient of kinetic friction between the ramp and the block is 0.23. (*a*) If the ramp is inclined 25° with the horizontal, how far along the surface of the ramp does the block slide before coming to a stop? (*b*) The block then slides back down the ramp. What is the coefficient of static friction between the block and the ramp if the block is not to slide back down the ramp?

Picture the Problem The force diagram shows the forces acting on the block as it slides up the ramp. Note that the block is accelerated by $\vec{f}_k$ and the x component of $\vec{F}_g$. We can use a constant-acceleration equation to express the displacement of the block up the ramp as a function of its acceleration and Newton's second law to find the acceleration of the block as it slides up the ramp.



(*a*) Use a constant-acceleration equation to relate the distance the block slides up the incline to its initial speed and acceleration:

$$v_x^2 = v_{0x}^2 + 2a_x\Delta x$$

or, because $v_x = 0$,

$$0 = v_{0x}^2 + 2a_x\Delta x \Rightarrow \Delta x = \frac{-v_{0x}^2}{2a_x} \quad (1)$$

Apply $\sum\vec{F} = m\vec{a}$ to the block:

$$\sum F_x = -f_k - F_g\sin\theta = ma_x \quad (2)$$

and

$$\sum F_y = F_n - F_g\cos\theta = 0 \quad (3)$$

Substituting $f_k = \mu_k F_n$ and $F_g = mg$ in equations (2) and (3) yields:

$$-\mu_k F_n - mg\sin\theta = ma_x \quad (4)$$

and

$$F_n - mg\cos\theta = 0 \quad (5)$$

Eliminate F_n between equations (4) and (5) to obtain:

$$-\mu_k mg\cos\theta - mg\sin\theta = ma_x$$

Solving for a_x yields:

$$a_x = -(\mu_k\cos\theta + \sin\theta)g$$

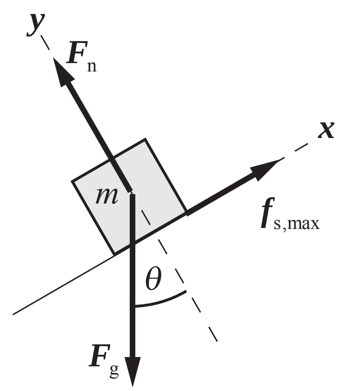
Substitute for a in equation (1) to obtain:

$$\Delta x = \frac{v_{0x}^2}{2(\mu_k\cos\theta + \sin\theta)g}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{(7.0\ \text{m/s})^2}{2\left[(0.23)\cos 25° + \sin 25°\right](9.81\ \text{m/s}^2)} = 3.957\ \text{m} = \boxed{4.0\ \text{m}}$$

(*b*) At the point at which the block is instantaneously at rest, static friction becomes operative and, if the static friction coefficient is too high, the block will not resume motion, but will remain at the high point. We can determine the maximum possible value of μs for which the block still slides back down the incline by considering the equality of the static friction force and the component of the weight of the block down the ramp.



Apply $\sum\vec{F} = m\vec{a}$ to the block when it is in equilibrium at the point at which it is momentarily at rest:

$$\sum F_x = f_{\text{s,max}} - F_g \sin\theta = 0 \quad (5)$$

and

$$\sum F_y = F_n - F_g \cos\theta = 0 \quad (6)$$

Solving equation (6) for F_n yields:

$$F_n = F_g \cos\theta$$

Because $f_{\text{s,max}} = \mu_s F_n$, equation (5) becomes:

$$\mu_s F_g \cos\theta - F_g \sin\theta = 0$$

or

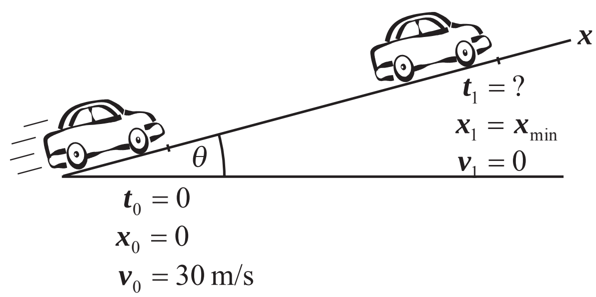
$$\mu_s \cos\theta - \sin\theta = 0 \Rightarrow \mu_s = \tan\theta$$

Substitute the numerical value of θ and evaluate μ_s:

$$\mu_s = \tan 25° = \boxed{0.47}$$

48 •• An automobile is going up a 15º grade at a speed of 30 m/s. The coefficient of static friction between the tires and the road is 0.70. (*a*) What minimum distance does it take to stop the car? (*b*) What minimum distance would it take to stop if the car were going down the grade?

Picture the Problem We can find the stopping distances by applying Newton's second law to the automobile and then using a constant-acceleration equation. The friction force the road exerts on the tires and the component of the car's weight along the incline combine to provide the net force that stops the car. The pictorial representation summarizes what we know about the motion of the car. We can use Newton's second law to determine the acceleration of the car and a constant-acceleration equation to obtain its stopping distance.



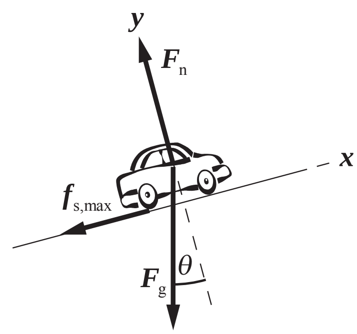
(*a*) Using a constant-acceleration equation, relate the final speed of the car to its initial speed, acceleration, and displacement; solve for its displacement:

$$v_{1x}^2 = v_{0x}^2 + 2a_{max,x}x_{min}$$

or, because $v_{1x} = 0$,

$$x_{min} = \frac{-v_{0x}^2}{2a_{max,x}} \quad (1)$$

Draw the free-body diagram for the car going up the incline:



Noting that $F_g = mg$, apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = -f_{s,max} - mg\sin\theta = ma_x \quad (2)$$

and

$$\sum F_y = F_n - mg\cos\theta = 0 \quad (3)$$

Substitute $f_{s,\,max} = \mu_s F_n$ and F_n from equation (3) in equation (2) and solve for $a_{max,x}$:

$$a_{max,x} = -g(\mu_s\cos\theta + \sin\theta)$$

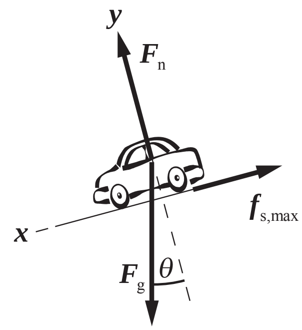
Substituting for $a_{max,x}$ in equation (1) yields:

$$x_{min} = \frac{v_{0x}^2}{2g(\mu_s\cos\theta + \sin\theta)}$$

Substitute numerical values and evaluate x_{min}:

$$x_{min} = \frac{(30\text{ m/s})^2}{2(9.81\text{ m/s}^2)((0.70)\cos 15° + \sin 15°)} = \boxed{49\text{ m}}$$

(*b*) When the car is going down the incline, the static friction force is up the incline as shown in the free-body diagram to the right. Note the change in coordinate system from Part (*a*).



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = mg\sin\theta - f_{\text{s,max}} = ma_x$$

and

$$\sum F_y = F_\text{n} - mg\cos\theta = 0$$

Proceed as in (*a*) to obtain:

$$a_{\max,x} = g(\sin\theta - \mu_\text{s}\cos\theta)$$

Substituting for $a_{\max,x}$ in equation (1) yields:

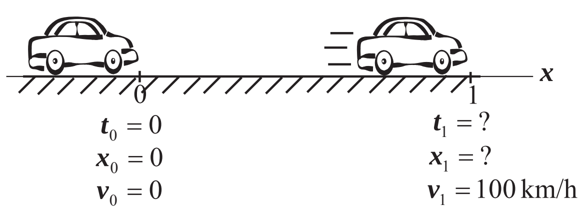
$$x_{\min} = \frac{-v_{0x}^2}{2g(\sin\theta - \mu_\text{s}\cos\theta)}$$

Substitute numerical values and evaluate $x_{\min}$:

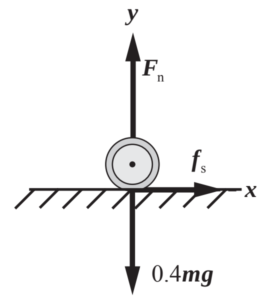
$$x_{\min} = \frac{-(30\text{ m/s})^2}{2(9.81\text{ m/s}^2)(\sin 15° - (0.70)\cos 15°)} = \boxed{0.11\text{ km}}$$

49 •• A rear-wheel-drive car supports 40 percent of its weight on its two drive wheels and has a coefficient of static friction of 0.70 with a horizontal straight road. (*a*) Find the vehicle's maximum acceleration. (*b*) What is the shortest possible time in which this car can achieve a speed of 100 km/h? (Assume the engine has unlimited power.)

Picture the Problem The friction force the road exerts on the tires provides the net force that accelerates the car. The pictorial representation summarizes what we know about the motion of the car. We can use Newton's second law to determine the acceleration of the car and a constant-acceleration equation to calculate how long it takes it to reach 100 km/h.



(*a*) Because 40% of the car's weight is on its two drive wheels and the accelerating friction forces act just on these wheels, the free-body diagram shows just the forces acting on the drive wheels.



Apply $\sum \vec{F} = m\vec{a}$ to the drive wheels:

$$\sum F_x = f_{s,max} = ma_{max,x} \quad (1)$$

and

$$\sum F_y = F_n - 0.4mg = 0 \quad (2)$$

Use the definition of $f_{s,\,max}$ in equation (1) and eliminate F_n between the two equations to obtain:

$$a_{max,x} = 0.4\mu_s g$$

Substitute numerical values and evaluate $a_{max,\,x}$:

$$a_{max,x} = 0.4(0.70)(9.81\,\text{m/s}^2) = 2.747\ \text{m/s}^2 = \boxed{2.7\,\text{m/s}^2}$$

(*b*) Using a constant-acceleration equation, relate the initial and final velocities of the car to its acceleration and the elapsed time; solve for the time:

$$v_{1,x} = v_{0,x} + a_{max,x}\Delta t$$

or, because $v_{0,x} = 0$ and $\Delta t = t_1$,

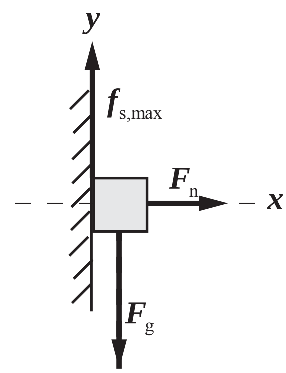
$$t_1 = \frac{v_{1,x}}{a_{max,x}}$$

Substitute numerical values and evaluate t_1:

$$t_1 = \frac{100\dfrac{\text{km}}{\text{h}} \times \dfrac{1\,\text{h}}{3600\,\text{s}} \times \dfrac{1000\,\text{m}}{\text{km}}}{2.747\,\text{m/s}^2} = \boxed{10\,\text{s}}$$

50 •• You and your best pal make a friendly bet that you can place a 2.0-kg box against the side of a cart, as in Figure 5-63, and that the box will not fall to the ground, even though you guarantee to use no hooks, ropes, fasteners, magnets, glue, or adhesives of any kind. When your friend accepts the bet, you begin pushing the cart in the direction shown in the figure. The coefficient of static friction between the box and the cart is 0.60. (*a*) Find the minimum acceleration for which you will win the bet. (*b*) What is the magnitude of the frictional force in this case? (*c*) Find the force of friction on the box if the acceleration is twice the minimum needed for the box not to fall. (*d*) Show that, for a box of any mass, the box will not fall if the magnitude of the forward acceleration is $a \geq g/\mu_s$, where μ_s is the coefficient of static friction.

Picture the Problem To hold the box in place, the acceleration of the cart and box must be great enough so that the static friction force acting on the box will equal the weight of the box. We can use Newton's second law to determine the minimum acceleration required.



(*a*) Noting that $F_g = mg$, apply $\sum \vec{F} = m\vec{a}$ to the box:

$$\sum F_x = F_n = ma_{\min,x} \quad (1)$$

and

$$\sum F_y = f_{s,max} - mg = 0 \quad (2)$$

Substituting $\mu_s F_n$ for $f_{s,\,max}$ in equation (2) yields:

$$\mu_s F_n - mg = 0$$

Substitute for F_n from equation (1) to obtain:

$$\mu_s (ma_{\min,x}) - mg = 0 \Rightarrow a_{\min,x} = \frac{g}{\mu_s}$$

Substitute numerical values and evaluate $a_{\min,x}$:

$$a_{\min,x} = \frac{9.81\,\text{m/s}^2}{0.60} = \boxed{16\,\text{m/s}^2}$$

(*b*) From equation (2) we have:

$$f_{s,max} = mg$$

Substitute numerical values and evaluate $f_{s,\,max}$:

$$f_{s,max} = (2.0\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{20\,\text{N}}$$

(*c*) If a is twice that required to hold the box in place, f_s will still have its maximum value given by:

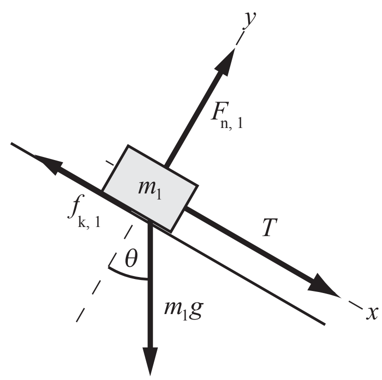
$$f_{s,max} = \boxed{20\,\text{N}}$$

(*d*) Because $a_{\min,x} = g/\mu_s$, the box will not fall if $a \geq g/\mu_s$.

51 •• Two blocks attached by a string (Figure 5-64) slide down a 10º incline. Block 1 has mass $m_1 = 0.80$ kg and block 2 has mass $m_2 = 0.25$ kg. In addition, the kinetic coefficients of friction between the blocks and the incline are 0.30 for block 1 and 0.20 for block 2. Find (*a*) the magnitude of the acceleration of the blocks, and (*b*) the tension in the string.

Picture the Problem Assume that the string is massless and does not stretch. Then the blocks have a common acceleration and the tension in the string acts on both blocks in accordance with Newton's third law of motion. Let down the incline be the +x direction. Draw the free-body diagrams for each block and apply Newton's second law of motion and the definition of the kinetic friction force to each block to obtain simultaneous equations in a_x and T.

Draw the free-body diagram for the block whose mass is m_1:



Apply $\sum\vec{F} = m\vec{a}$ to the upper block:

$$\sum F_x = -f_{k,1} + T + m_1 g\sin\theta = m_1 a \quad (1)$$

and

$$\sum F_y = F_{n,1} - m_1 g\cos\theta = 0 \quad (2)$$

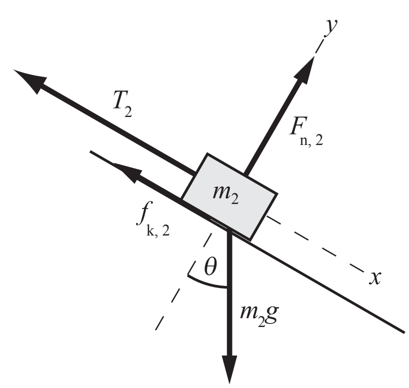
The relationship between $f_{k,1}$ and $F_{n,1}$ is:

$$f_{k,1} = \mu_{k,1}F_{n,1} \quad (3)$$

Eliminate $f_{k,1}$ and $F_{n,1}$ between (1), (2), and (3) to obtain:

$$-\mu_{k,1}m_1 g\cos\theta + T + m_1 g\sin\theta = m_1 a \quad (4)$$

Draw the free-body diagram for the block whose mass is m_2:



Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\sum F_x = -f_{k,2} - T + m_2 g \sin\theta = m_2 a \quad (5)$$

and

$$\sum F_y = F_{n,2} - m_2 g \cos\theta = 0 \quad (6)$$

The relationship between $f_{k,2}$ and $F_{n,2}$ is:

$$f_{k,2} = \mu_{k,2} F_{n,2} \quad (7)$$

Eliminate $f_{k,2}$ and $F_{n,2}$ between (5), (6), and (7) to obtain:

$$-\mu_{k,2} m_2 g \cos\theta - T + m_2 g \sin\theta = m_1 a \quad (8)$$

Add equations (4) and (8) to eliminate T, and solve for $|a|$:

$$|a| = \left|\left[\sin\theta - \frac{\mu_{k,1} m_1 + \mu_{k,2} m_2}{m_1 + m_2}\cos\theta\right] g\right|$$

Substitute numerical values and evaluate $|a|$:

$$|a| = \left|\left[\sin 10^\circ - \frac{(0.20)(0.25\,\text{kg}) + (0.30)(0.80\,\text{kg})}{0.25\,\text{kg} + 0.80\,\text{kg}}\cos 10^\circ\right](9.81\,\text{m/s}^2)\right| = \boxed{0.96\,\text{m/s}^2}$$

(*b*) Eliminate *a* between equations (4) and (8) and solve for $T = T_1 = T_2$ to obtain:

$$T = \frac{m_1 m_2 (\mu_{k,2} - \mu_{k,1}) g \cos\theta}{m_1 + m_2}$$

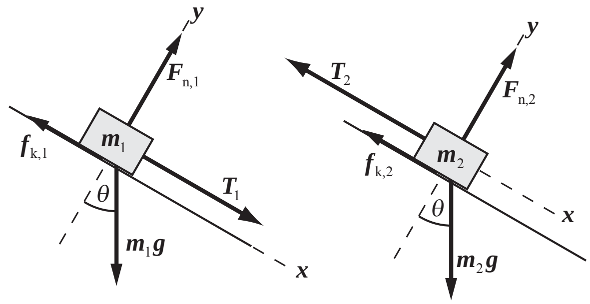
Substitute numerical values and evaluate T:

$$T = \frac{(0.25\,\text{kg})(0.80\,\text{kg})(0.30 - 0.20)(9.81\,\text{m/s}^2)\cos 10^\circ}{0.25\,\text{kg} + 0.80\,\text{kg}} = \boxed{0.18\,\text{N}}$$

52 •• Two blocks of masses m_1 and m_2 are sliding down an incline as shown in Figure 5-64. They are connected by a massless *rod*. The coefficients of kinetic friction between the block and the surface are μ_1 for block 1 and μ_2 for block 2. (*a*) Determine the acceleration of the two blocks. (*b*) Determine the force that the rod exerts on each of the two blocks. Show that the forces are both 0 when $\mu_1 = \mu_2$ and give a simple, nonmathematical argument why this is true.

Picture the Problem The free-body diagrams show the forces acting on the two blocks as they slide down the incline. Down the incline has been chosen as the +*x* direction. *T* is the force transmitted by the rod; it can be either tensile ($T > 0$) or

compressive ($T < 0$). By applying Newton's second law to these blocks, we can obtain equations in T and a_x from which we can eliminate either by solving them simultaneously. Once we have expressed T, the role of the rod will become apparent.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to block 1:

$$\sum F_x = T_1 + m_1 g \sin\theta - f_{k,1} = m_1 a_x$$

and

$$\sum F_y = F_{n,1} - m_1 g \cos\theta = 0$$

Apply $\sum \vec{F} = m\vec{a}$ to block 2:

$$\sum F_x = m_2 g \sin\theta - T_2 - f_{k,2} = m_2 a_x$$

and

$$\sum F_y = F_{n,2} - m_2 g \cos\theta = 0$$

Letting $T_1 = T_2 = T$, use the definition of the kinetic friction force to eliminate $f_{k,1}$ and $F_{n,1}$ between the equations for block 1 and $f_{k,2}$ and $F_{n,1}$ between the equations for block 2 to obtain:

$$m_1 a_x = m_1 g \sin\theta + T - \mu_1 m_1 g \cos\theta \quad (1)$$

and

$$m_2 a_x = m_2 g \sin\theta - T - \mu_2 m_2 g \cos\theta \quad (2)$$

Add equations (1) and (2) to eliminate T and solve for a_x:

$$a_x = \boxed{g\left(\sin\theta - \frac{\mu_1 m_1 + \mu_2 m_2}{m_1 + m_2}\cos\theta\right)}$$

(*b*) Rewrite equations (1) and (2) by dividing both sides of (1) by m_1 and both sides of (2) by m_2 to obtain.

$$a_x = g\sin\theta + \frac{T}{m_1} - \mu_1 g\cos\theta \quad (3)$$

and

$$a_x = g\sin\theta - \frac{T}{m_2} - \mu_2 g\cos\theta \quad (4)$$

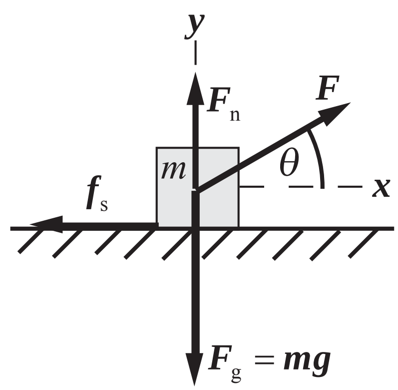
Subtracting (4) from (3) and rearranging yields:

$$T = \boxed{\left(\frac{m_1 m_2}{m_1 + m_2}\right)(\mu_1 - \mu_2) g \cos\theta}$$

If $\mu_1 = \mu_2$, $T = 0$ and the blocks move down the incline with the same acceleration of $g(\sin\theta - \mu\cos\theta)$. Inserting a stick between them can't change this; therefore, the stick must exert no force on either block.

53 •• **[SSM]** A block of mass m rests on a horizontal table (Figure 5-65). The block is pulled by a massless rope with a force $\vec{F}$ at an angle θ. The coefficient of static friction is 0.60. The minimum value of the force needed to move the block depends on the angle θ. (*a*) Discuss qualitatively how you would expect this force to depend on θ. (*b*) Compute the force for the angles $\theta = 0°$, 10°, 20°, 30°, 40°, 50°, and 60°, and make a plot of F versus θ for $mg = 400$ N. From your plot, at what angle is it most efficient to apply the force to move the block?

Picture the Problem The vertical component of $\vec{F}$ reduces the normal force; hence, the static friction force between the surface and the block. The horizontal component is responsible for any tendency to move and equals the static friction force until it exceeds its maximum value. We can apply Newton's second law to the box, under equilibrium conditions, to relate F to θ.



(*a*) The static-friction force opposes the motion of the object, and the maximum value of the static-friction force is proportional to the normal force F_N. The normal force is equal to the weight minus the vertical component F_V of the force F. Keeping the magnitude F constant while increasing θ from zero results in an increase in F_V and a decrease in F_n; thus decreasing the maximum static-friction force f_{max}. The object will begin to move if the horizontal component F_H of the force F exceeds f_{max}. An increase in θ results in a decrease in F_H. As θ increases from 0, the decrease in F_N is larger than the decrease in F_H, so the object is more and more likely to slip. However, as θ approaches 90°, F_H approaches zero and no movement will be initiated. If F is large enough and if θ increases from 0, then at some value of θ the block will start to move.

(*b*) Apply $\sum\vec{F} = m\vec{a}$ to the block:

$$\sum F_x = F\cos\theta - f_s = 0 \qquad (1)$$

and

$$\sum F_y = F_n + F\sin\theta - mg = 0 \qquad (2)$$

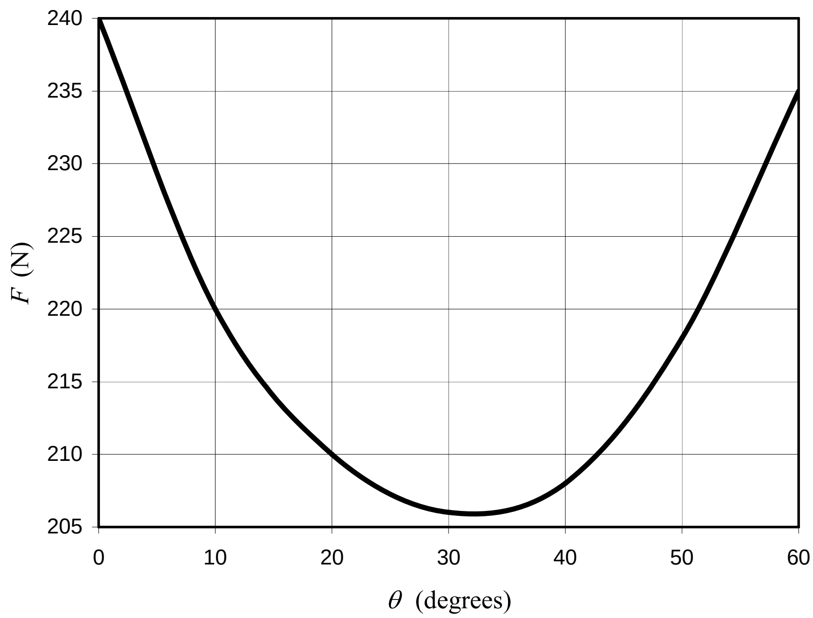
Assuming that $f_s = f_{s,max}$, eliminate f_s and F_n between equations (1) and (2) and solve for F:

$$F = \frac{\mu_s mg}{\cos\theta + \mu_s \sin\theta}$$

Use this function with mg = 400 N to generate the following table:

θ	(deg)	0	10	20	30	40	50	60
F	(N)	240	220	210	206	208	218	235

The following graph of $F(\theta)$ was plotted using a spreadsheet program.

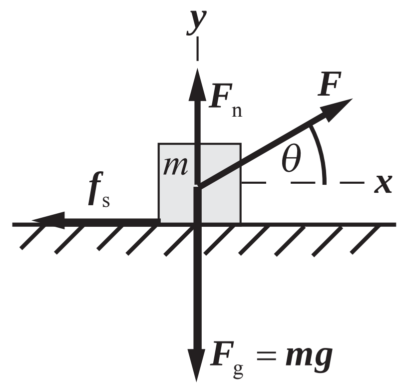


From the graph, we can see that the minimum value for F occurs when $\theta \approx 32°$.

Remarks: An alternative to manually plotting F as a function of θ or using a spreadsheet program is to use a graphing calculator to enter and graph the function.

54 •• Consider the block in Problem 53. Show that, in general, the following results hold for a block of mass m resting on a horizontal surface whose coefficient of static friction is μ_s. (*a*) If you want to apply the *minimum* possible force to move the block, you should apply it with the force pulling upward at an angle $\theta_{min} = \tan^{-1}\mu_s$, and (*b*) the minimum force necessary to start the block moving is $F_{min} = \left(\mu_s/\sqrt{1-\mu_s^2}\right)mg$. (*c*) Once the block starts moving, if you want to apply the least possible force to *keep* it moving, should you keep the angle at which you are pulling the same? increase it? decrease it?

Picture the Problem The free-body diagram shows the forces acting on the block. We can apply Newton's second law, under equilibrium conditions, to relate F to θ and then set its derivative with respect to θ equal to zero to find the value of θ that minimizes F.



(a) Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\sum F_x = F\cos\theta - f_s = 0 \quad (1)$$

and

$$\sum F_y = F_n + F\sin\theta - mg = 0 \quad (2)$$

Assuming that $f_s = f_{s,max}$, eliminate f_s and F_n between equations (1) and (2) and solve for F:

$$F = \frac{\mu_s mg}{\cos\theta + \mu_s \sin\theta} \quad (3)$$

To find θ_{min}, differentiate F with respect to θ and set the derivative equal to zero for extrema of the function:

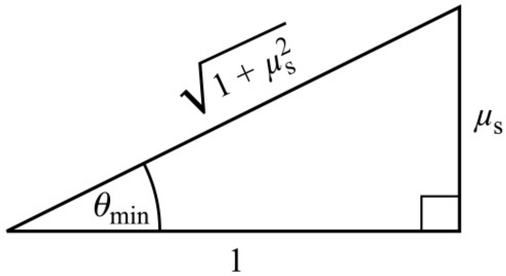
$$\frac{dF}{d\theta} = \frac{(\cos\theta + \mu_s \sin\theta)\frac{d}{d\theta}(\mu_s mg)}{(\cos\theta + \mu_s \sin\theta)^2} - \frac{\mu_s mg \frac{d}{d\theta}(\cos\theta + \mu_s \sin\theta)}{(\cos\theta + \mu_s \sin\theta)^2}$$

$$= \frac{\mu_s mg(-\sin\theta + \mu_s \cos\theta)}{(\cos\theta + \mu_s \sin\theta)^2} = 0 \text{ for extrema}$$

Solving for θ_{min} yields:

$$\theta_{min} = \boxed{\tan^{-1}\mu_s}$$

(b) Use the reference triangle shown below to substitute for $\cos\theta$ and $\sin\theta$ in equation (3):



$$F_{min} = \frac{\mu_s mg}{\frac{1}{\sqrt{1+\mu_s^2}} + \mu_s \frac{\mu_s}{\sqrt{1+\mu_s^2}}}$$

$$= \frac{\mu_s mg}{\frac{1+\mu_s^2}{\sqrt{1+\mu_s^2}}}$$

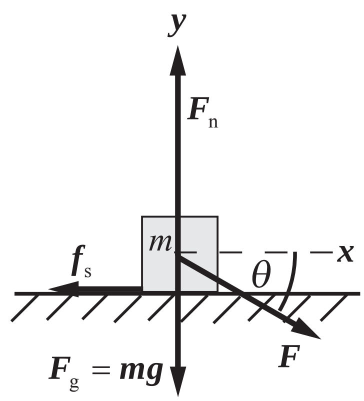
$$= \boxed{\frac{\mu_s}{\sqrt{1+\mu_s^2}} mg}$$

(*c*) The coefficient of kinetic friction is less than the coefficient of static friction. An analysis identical to the one above shows that the minimum force one should apply to keep the block moving should be applied at an angle given by $\theta_{\text{min}} = \tan^{-1}\mu_{\text{k}}$. Therefore, once the block is moving, the coefficient of friction will decrease, so the angle can be decreased.

55 •• Answer the questions in Problem 54, but for a force $\vec{F}$ that pushes down on the block at an angle θ *below* the horizontal.

Picture the Problem The vertical component of $\vec{F}$ increases the normal force and the static friction force between the surface and the block. The horizontal component is responsible for any tendency to move and equals the static friction force until it exceeds its maximum value. We can apply Newton's second law to the box, under equilibrium conditions, to relate F to θ.

(*a*) As θ increases from zero, F increases the normal force exerted by the surface and the static friction force. As the horizontal component of F decreases with increasing θ, one would expect F to continue to increase.



(*b*) Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\sum F_x = F\cos\theta - f_{\text{s}} = 0 \qquad (1)$$

and

$$\sum F_y = F_{\text{n}} - F\sin\theta - mg = 0 \qquad (2)$$

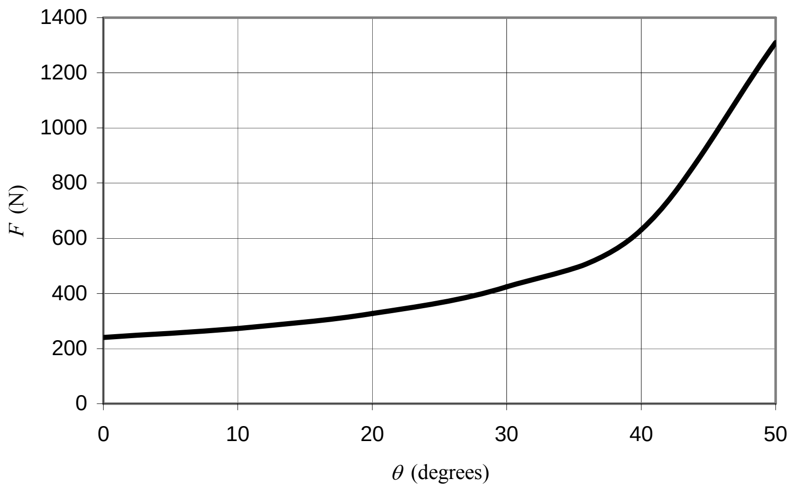
Assuming that $f_{\text{s}} = f_{\text{s,max}}$, eliminate f_{s} and F_{n} between equations (1) and (2) and solve for F:

$$F = \frac{\mu_{\text{s}} mg}{\cos\theta - \mu_{\text{s}}\sin\theta} \qquad (3)$$

Use this function with mg = 400 N to generate the table shown below.

θ	(deg)	0	10	20	30	40	50	60
F	(N)	240	273	327	424	631	1310	very large

The following graph of F as a function of θ, plotted using a spreadsheet program, confirms our prediction that F continues to increase with θ.



(*a*) From the graph we see that: $\theta_{min} = \boxed{0°}$

(*b*) Evaluate equation (3) for $\theta = 0°$ to obtain:

$$F = \frac{\mu_s mg}{\cos 0° - \mu_s \sin 0°} = \boxed{\mu_s mg}$$

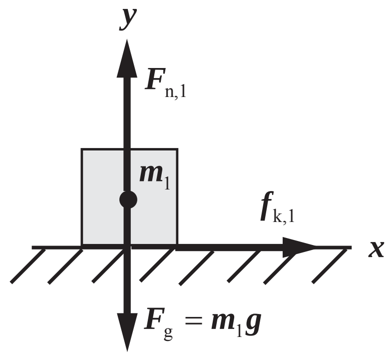
(*c*) You should keep the angle at 0°.

Remarks: An alternative to the use of a spreadsheet program is to use a graphing calculator to graph the function.

56 •• A 100-kg mass is pulled along a frictionless surface by a horizontal force $\vec{F}$ such that its acceleration is $a_1 = 6.00\ \text{m/s}^2$ (Figure 5-66). A 20.0-kg mass slides along the top of the 100-kg mass and has an acceleration of $a_2 = 4.00\ \text{m/s}^2$. (It thus slides backward relative to the 100-kg mass.) (*a*) What is the frictional force exerted by the 100-kg mass on the 20.0-kg mass? (*b*) What is the net force acting on the 100-kg mass? What is the force F? (*c*) After the 20.0-kg mass falls off the 100-kg mass, what is the acceleration of the 100-kg mass? (Assume that the force F does not change.)

Picture the Problem The forces acting on each of these masses are shown in the free-body diagrams below. m_1 represents the mass of the 20.0-kg mass and m_2 that of the 100-kg mass. As described by Newton's 3rd law, the normal reaction force $F_{n,1}$ and the friction force $f_{k,1}$ ($= f_{k,2}$) act on both masses but in opposite directions. Newton's second law and the definition of kinetic friction forces can be used to determine the various forces and the acceleration called for in this problem.

(*a*) Draw a free-body diagram showing the forces acting on the block whose mass is 20 kg:



Apply $\sum \vec{F} = m\vec{a}$ to this mass:

$$\sum F_x = f_{k,1} = m_1 a_{1x} \quad (1)$$

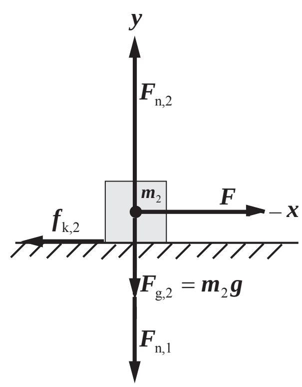
and

$$\sum F_y = F_{n,1} - m_1 g = 0 \quad (2)$$

Substitute numerical values in equation (1) and evaluate $f_{k,1}$:

$$f_{k,1} = (20.0\text{ kg})(4.00\text{ m/s}^2) = \boxed{80.0\text{ N}}$$

(*b*) Draw a free-body diagram showing the forces acting on the block whose mass is 100 kg:



Apply $\sum F_x = ma_x$ to the 100-kg object and evaluate F_{net}:

$$F_{\text{net}} = m_2 a_{2x} = (100\text{ kg})(6.00\text{ m/s}^2)$$
$$= \boxed{600\text{ N}}$$

Express F in terms of F_{net} and $f_{k,2}$:

$$F = F_{\text{net}} + f_{k,2}$$

Substitute numerical values and evaluate F:

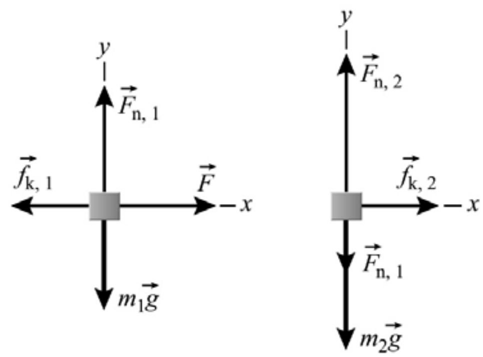
$$F = 600\text{ N} + 80.0\text{ N} = \boxed{680\text{ N}}$$

(*c*) When the 20.0-kg object falls off, the 680-N force acts just on the 100-kg object and its acceleration is given by Newton's second law:

$$a = \frac{F_{\text{net}}}{m} = \frac{680\text{ N}}{100\text{ kg}} = \boxed{6.80\text{ m/s}^2}$$

57 •• A 60.0-kg block slides along the top of a 100-kg block. The 60.0-kg block has an acceleration of 3.0 m/s^2 when a horizontal force of 320 N is applied, as in Figure 5-67. There is no friction between the 100-kg block and a horizontal frictionless surface, but there is friction between the two blocks. (*a*) Find the coefficient of kinetic friction between the blocks. (*b*) Find the acceleration of the 100-kg block during the time that the 60.0-kg block remains in contact.

Picture the Problem The forces acting on each of these blocks are shown in the free-body diagrams to the right. m_1 represents the mass of the 60-kg block and m_2 that of the 100-kg block. As described by Newton's 3rd law, the normal reaction force $F_{n,1}$ and the friction force $f_{k,1}$ (= $f_{k,2}$) act on both objects but in opposite directions. Newton's second law and the definition of kinetic friction forces can be used to determine the coefficient of kinetic friction and acceleration of the 100-kg block.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the 60-kg block:

$$\sum F_x = F - f_{k,1} = m_1 a_{1,x} \quad (1)$$

and

$$\sum F_y = F_{n,1} - m_1 g = 0 \quad (2)$$

Apply $\sum F_x = ma_x$ to the 100-kg block:

$$f_{k,2} = m_2 a_{2,x} \quad (3)$$

Using equation (2), express the relationship between the kinetic friction forces $\vec{f}_{k,1}$ and $\vec{f}_{k,2}$:

$$f_{k,1} = f_{k,2} = f_k = \mu_k F_{n,1} = \mu_k m_1 g \quad (4)$$

Substitute for $f_{k,1}$ in equation (1) and solve for μ_k:

$$\mu_k = \frac{F - m_1 a_1}{m_1 g}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{320\,\text{N} - (60\,\text{kg})(3.0\,\text{m/s}^2)}{(60\,\text{kg})(9.81\,\text{m/s}^2)} = 0.238 = \boxed{0.24}$$

(*b*) Substitute for $f_{k,2}$ in equation (3) and solve for a_2 to obtain:

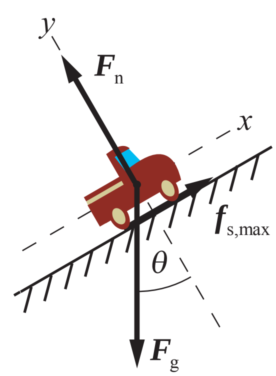
$$a_{2,x} = \frac{\mu_k m_1 g}{m_2}$$

Substitute numerical values and evaluate $a_{2,x}$:

$$a_{2,x} = \frac{(0.238)(60\,\text{kg})(9.81\,\text{m/s}^2)}{100\,\text{kg}} = \boxed{1.4\,\text{m/s}^2}$$

58 •• The coefficient of static friction between a rubber tire and the road surface is 0.85. What is the maximum acceleration of a 1000-kg four-wheel-drive truck if the road makes an angle of 12º with the horizontal and the truck is (*a*) climbing and (*b*) descending?

Picture the Problem Choose a coordinate system in which the $+x$ direction is up the incline and apply Newton's second law of motion. The free-body diagram shows the truck climbing the incline with maximum acceleration.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the truck when it is climbing the incline:

$$\sum F_x = f_{s,max} - mg\sin\theta = ma_x \quad (1)$$

and

$$\sum F_y = F_n - mg\cos\theta = 0 \quad (2)$$

Solve equation (2) for F_n and use the definition $f_{s,max}$ to obtain:

$$f_{s,max} = \mu_s mg\cos\theta \quad (3)$$

Substitute $f_{s,max}$ in equation (1) and solve for a_x:

$$a_x = g(\mu_s\cos\theta - \sin\theta)$$

Substitute numerical values and evaluate a_x:

$$a_x = (9.81\,\text{m/s}^2)[(0.85)\cos 12° - \sin 12°] = \boxed{6.1\,\text{m/s}^2}$$

(*b*) When the truck is descending the incline with maximum acceleration, the static friction force points down the incline; that is, its direction is reversed Apply $\sum F_x = ma_x$ to the truck under these conditions to obtain:

$$-f_{s,max} - mg\sin\theta = ma_x \qquad (4)$$

Substituting for $f_{s,max}$ in equation (4) and solving for a_x gives:

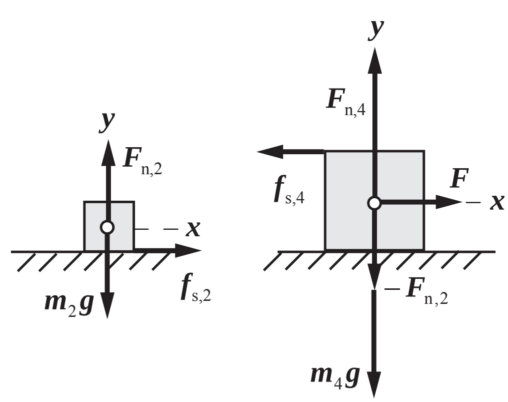
$$a_x = -g(\mu_s \cos\theta + \sin\theta)$$

Substitute numerical values and evaluate a_x:

$$a_x = (-9.81\,\text{m/s}^2)[(0.85)\cos 12° + \sin 12°] = \boxed{-10\,\text{m/s}^2}$$

59 •• A 2.0-kg block sits on a 4.0-kg block that is on a frictionless table (Figure 5-68). The coefficients of friction between the blocks are $\mu_s = 0.30$ and $\mu_k = 0.20$. (*a*) What is the maximum horizontal force *F* that can be applied to the 4.0-kg block if the 2.0-kg block is not to slip? (*b*) If *F* has half this value, find the acceleration of each block and the force of friction acting on each block. (*c*) If *F* is twice the value found in (*a*), find the acceleration of each block..

Picture the Problem The forces acting on each of the blocks are shown in the free-body diagrams to the right. m_2 represents the mass of the 2.0-kg block and m_4 that of the 4.0-kg block. As described by Newton's 3rd law, the normal reaction force $F_{n,2}$ and the friction force $f_{s,2}$ (= $f_{s,4}$) act on both objects but in opposite directions. Newton's second law and the definition of the maximum static friction force can be used to determine the maximum force acting on the 4.0-kg block for which the 2.0-kg block does not slide.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the 2.0-kg block:

$$\sum F_x = f_{s,2,max} = m_2 a_{2,max} \qquad (1)$$

and

$$\sum F_y = F_{n,2} - m_2 g = 0 \qquad (2)$$

Apply $\sum \vec{F} = m\vec{a}$ to the 4.0-kg block:

$$\sum F_x = F - f_{\text{s,2,max}} = m_4 a_{4,\text{max}} \quad (3)$$

and

$$\sum F_y = F_{\text{n},4} - F_{\text{n},2} - m_4 g = 0 \quad (4)$$

Using equation (2), express the relationship between the static friction forces $\vec{f}_{\text{s,2,max}}$ and $\vec{f}_{\text{s,4,max}}$:

$$f_{\text{s,2,max}} = f_{s,4,\text{max}} = \mu_\text{s} m_2 g \quad (5)$$

Substitute for $\vec{f}_{\text{s,2,max}}$ in equation (1) and solve for $a_{2,\text{max}}$:

$$a_{2,\text{max}} = \mu_\text{s} g$$

Solve equation (3) for $F = F_\text{max}$ and substitute for $a_{2,\text{max}}$ and $a_{4,\text{max}}$ to obtain:

$$F_\text{max} = m_4 \mu_\text{s} g + \mu_\text{s} m_2 g = (m_4 + m_2)\mu_\text{s} g$$

Substitute numerical values and evaluate F_max:

$$F_\text{max} = (4.0\,\text{kg} + 2.0\,\text{kg})(0.30)(9.81\,\text{m/s}^2) = 17.66\,\text{N} = \boxed{18\,\text{N}}$$

(*b*) Use Newton's second law to express the acceleration of the blocks moving as a unit:

$$a_x = \frac{F}{m_1 + m_2} = \frac{\frac{1}{2}F_\text{max}}{m_1 + m_2}$$

Substitute numerical values and evaluate *a*:

$$a_x = \frac{\frac{1}{2}(17.66\,\text{N})}{2.0\,\text{kg} + 4.0\,\text{kg}} = 1.472\,\text{m/s}^2 = \boxed{1.5\,\text{m/s}^2}$$

Because the friction forces are an action-reaction pair, the friction force acting on each block is given by:

$$f_\text{s} = m_1 a_x$$

Substitute numerical values and evaluate f_s:

$$f_\text{s} = (2.0\,\text{kg})(1.472\,\text{m/s}^2) = \boxed{2.9\,\text{N}}$$

(c) If $F = 2F_{max}$, then the 2.0-kg block slips on the 4.0-kg block and the friction force (now kinetic) is given by:

$$f = f_k = \mu_k m_2 g$$

Use $\sum F_x = ma_x$ to relate the acceleration of the 2.0-kg block to the net force acting on it and solve for $a_{2,x}$:

$$f_k = \mu_k m_1 g = m_2 a_{2,x}$$

and

$$a_{2,x} = \mu_k g$$

Substitute numerical values and evaluate $a_{2,x}$:

$$a_{2,x} = (0.20)(9.81\ \text{m/s}^2) = 1.96\ \text{m/s}^2 = \boxed{2.0\ \text{m/s}^2}$$

Use $\sum F_x = ma_x$ to relate the acceleration of the 4.0-kg block to the net force acting on it:

$$F - \mu_k m_2 g = m_4 a_{4,x}$$

Solving for $a_{4,x}$ yields:

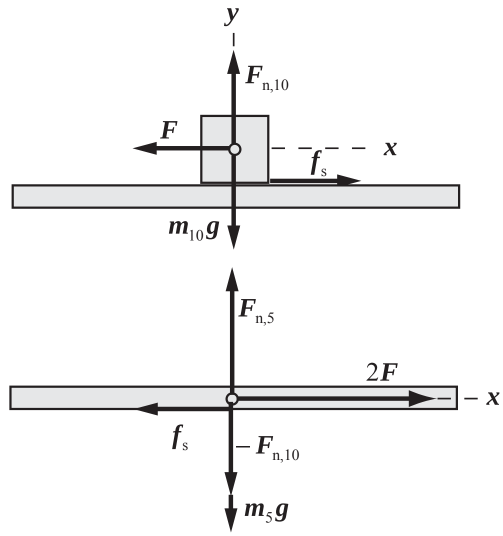
$$a_{4,x} = \frac{F - \mu_k m_2 g}{m_4}$$

Substitute numerical values and evaluate $a_{4,x}$:

$$a_{4,x} = \frac{2(17.66\ \text{N}) - (0.20)(2.0\ \text{kg})(9.81\ \text{m/s}^2)}{4.0\ \text{kg}} = \boxed{7.8\ \text{m/s}^2}$$

60 •• A 10.0-kg block rests on a 5.0-kg bracket, as shown in Figure 5-69. The 5.0-kg bracket sits on a frictionless surface. The coefficients of friction between the 10.0-kg block and the bracket on which it rests are $\mu_s = 0.40$ and $\mu_k = 0.30$. (a) What is the maximum force F that can be applied if the 10.0-kg block is not to slide on the bracket? (b) What is the corresponding acceleration of the 5.0-kg bracket?

Picture the Problem The top diagram shows the forces action on the 10-kg block and the bottom diagram shows the forces acting on the 5.0-kg bracket. If the block is not to slide on the bracket, the maximum value for $\vec{F}$ must equal the maximum value of f_s. This value for $\vec{F}$ will produce the maximum acceleration of block and bracket system. We can apply Newton's second law and the definition of $f_{s,max}$ to first calculate the maximum acceleration and then the maximum value of F.



Apply $\sum\vec{F} = m\vec{a}$ to the 10-kg block when it is experiencing its maximum acceleration:

$$\sum F_x = f_{s,max} - F = m_{10}a_{10,max} \quad (1)$$

and

$$\sum F_y = F_{n,10} - m_{10}g = 0 \quad (2)$$

Express the static friction force acting on the 10-kg block:

$$f_{s,max} = \mu_s F_{n,10} \quad (3)$$

Eliminate $f_{s,max}$ and $F_{n,10}$ from equations (1), (2) and (3) to obtain:

$$\mu_s m_{10}g - F = m_{10}a_{10,max} \quad (4)$$

Apply $\sum F_x = ma_x$ to the bracket to obtain:

$$2F - \mu_s m_{10}g = m_5 a_{5,max} \quad (5)$$

Because $a_{5,max} = a_{10,max}$, denote this acceleration by a_{max}. Eliminate F from equations (4) and (5) and solve for a_{max}:

$$a_{max} = \frac{\mu_s m_{10}g}{m_5 + 2m_{10}}$$

(b) Substitute numerical values and evaluate a_{max}:

$$a_{max} = \frac{(0.40)(10\,\text{kg})(9.81\,\text{m/s}^2)}{5.0\,\text{kg} + 2(10\,\text{kg})} = 1.57\,\text{m/s}^2 = \boxed{1.6\,\text{m/s}^2}$$

Solve equation (4) for $F = F_{max}$:

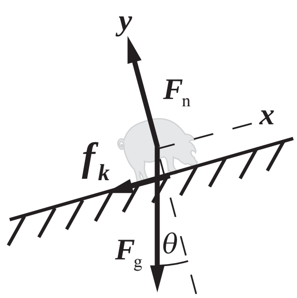
$$F = \mu_s m_{10}g - m_{10}a_{max} = m_{10}(\mu_s g - a_{max})$$

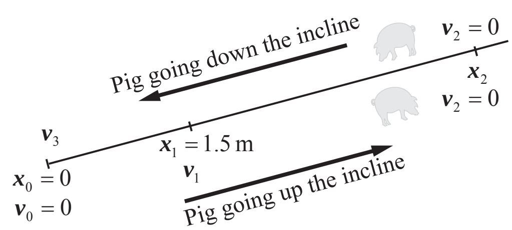
(a) Substitute numerical values and evaluate F:

$$F = (10\,\text{kg})\left[(0.40)(9.81\,\text{m/s}^2) - 1.57\,\text{m/s}^2\right] = \boxed{24\,\text{N}}$$

61 ••• You and your friends push a 75.0-kg greased pig up an aluminum slide at the county fair, starting from the low end of the slide. The coefficient of kinetic friction between the pig and the slide is 0.070. (a) All of you pushing together (parallel to the incline) manage to accelerate the pig from rest at the constant rate of 5.0 m/s^2 over a distance of 1.5 m, at which point you release the pig. The pig continues up the slide, reaching a maximum *vertical height* above its release point of 45 cm. What is the angle of inclination of the slide? (b) At the maximum height the pig turns around and begins to slip down once slide, how fast is it moving when it arrives at the low end of the slide?

Picture the Problem The free-body diagram shows the forces acting on the pig sometime after you and your friends have stopped pushing on it but before it has momentarily stopped moving up the slide. We can use constant-acceleration equations and Newton's second law to find the angle of inclination of the slide and the pig's speed when it returns to bottom of the slide. The pictorial representation assigns a coordinate system and names to the variables that we need to consider in solving this problem.





(a) Apply $\sum \vec{F} = m\vec{a}$ to the pig:

$$\sum F_x = -f_k - F_g \sin\theta = ma_x \qquad (1)$$

and

$$\sum F_y = F_n - F_g \cos\theta = 0 \qquad (2)$$

Substitute $f_k = \mu_k F_n$ and $F_g = mg$ in equation (1) to obtain:

$$-\mu_k F_n - mg\sin\theta = ma_x \qquad (3)$$

Solving equation (2) for F_n yields:

$$F_n = F_g \cos\theta$$

Substitute for F_n in equation (3) to obtain:

$$-\mu_k mg\cos\theta - mg\sin\theta = ma_x$$

Solving for a_x yields:

$$a_x = -g(\mu_k \cos\theta + \sin\theta) \qquad (4)$$

Use a constant-acceleration equation to relate the distance d the pig slides up the ramp to its speed after you and your friends have stopped pushing, its final speed, and its acceleration:

$$v_2^2 = v_1^2 + 2a_x d$$

or, because $v_2 = 0$,

$$0 = v_1^2 + 2a_x d$$

Substituting for a_x from equation (4) yields:

$$0 = v_1^2 - 2g(\mu_k \cos\theta + \sin\theta)d \qquad (5)$$

Use a constant-acceleration equation to relate the pig's speed v_1 after being accelerated to the distance Δx over which it was accelerated:

$$v_1^2 = v_0^2 + 2a_x \Delta x$$

or, because $v_0 = 0$,

$$v_1^2 = 2a_x \Delta x$$

Substitute for v_1^2 in equation (5) to obtain:

$$0 = 2a_x \Delta x - 2g(\mu_k \cos\theta + \sin\theta)d \qquad (6)$$

Use trigonometry to relate the vertical distance h risen by the pig during its slide to the distance d it moves up the slide:

$$h = d\sin\theta \Rightarrow d = \frac{h}{\sin\theta}$$

Substituting for d in equation (6) gives:

$$0 = 2a_x \Delta x - 2g(\mu_k \cos\theta + \sin\theta)\frac{h}{\sin\theta}$$

Solve for θ to obtain:

$$\theta = \tan^{-1}\left[\frac{\mu_k h}{\dfrac{a_x \Delta x}{g} - h}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left[\frac{(0.070)(0.45\ \text{m})}{\dfrac{(5.0\ \text{m/s}^2)(1.5\ \text{m})}{9.81\ \text{m/s}^2} - 0.45\ \text{m}}\right]$$

$$= 5.719° = \boxed{5.7°}$$

(b) Use a constant-acceleration equation to express v_3 as a function of the pig's acceleration down the incline a_{down}, its initial speed v_2, the distance Δd it slides down the incline:

$$v_3^2 = v_2^2 + 2a_{\text{down}} \Delta d$$

or, because $v_2 = 0$,

$$v_3^2 = 2a_{\text{down}} \Delta d \Rightarrow v_3 = \sqrt{2a_{\text{down}} \Delta d} \qquad (7)$$

When the pig is sliding down the incline, the kinetic friction force shown in the free-body diagram is reversed (it points up the incline … opposing the pig's motion) and the pig's acceleration is:

$$a_{\text{down}} = g(\sin\theta - \mu_{\text{k}}\cos\theta)$$

Substitute for a_{down} in equation (7) to obtain:

$$v_3 = \sqrt{2g(\sin\theta - \mu_{\text{k}}\cos\theta)\Delta d} \quad (8)$$

Δd is the sum of the distances the pig was pushed and then slid to a momentary stop:

$$\Delta d = 1.5\text{ m} + \frac{d}{\sin\theta}$$

Substituting for Δd in equation (8) yields:

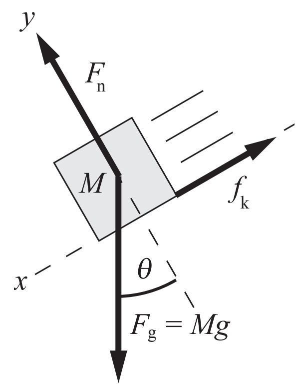
$$v_3 = \sqrt{2g(\sin\theta - \mu_{\text{k}}\cos\theta)\left(1.5\text{ m} + \frac{d}{\sin\theta}\right)}$$

Substitute numerical values and evaluate v_3:

$$v_3 = \sqrt{2(9.81\text{ m/s}^2)[\sin 5.719° - (0.070)\cos 5.719°]\left(1.5\text{ m} + \frac{0.45\text{ m}}{\sin 5.719°}\right)} = \boxed{1.9\text{ m/s}}$$

62 ••• A 100-kg block on an inclined plane is attached to another block of mass *m* via a string, as in Figure 5-70. The coefficients of static and kinetic friction for the block and the incline are $\mu_{\text{s}} = 0.40$ and $\mu_{\text{k}} = 0.20$ and the plane is inclined 18º with horizontal. (*a*) Determine the range of values for *m*, the mass of the hanging block, for which the 100-kg block will not move unless disturbed, but if nudged, will slide down the incline. (*b*) Determine a range of values for *m* for which the 100-kg block will not move unless nudged, but if nudged will slide up the incline.

Picture the Problem The free-body diagram shows the block sliding down the incline under the influence of a friction force, its weight, and the normal force exerted on it by the inclined surface. We can find the range of values for *m* for the two situations described in the problem statement by applying Newton's second law of motion to, first, the conditions under which the block will not slide if pushed, and secondly, if pushed, the block will slide up the incline.



(*a*) Assume that the block is sliding down the incline with a constant velocity and with no hanging weight ($m = 0$) and apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\sum F_x = -f_k + Mg\sin\theta = 0$$
and
$$\sum F_y = F_n - Mg\cos\theta = 0$$

Using $f_k = \mu_k F_n$, eliminate F_n between the two equations and solve for the net force acting on the block:

$$F_{net} = -\mu_k Mg\cos\theta + Mg\sin\theta$$

If the block is moving, this net force must be nonnegative and:

$$(-\mu_k\cos\theta + \sin\theta)Mg \geq 0$$

This condition requires that:

$$\mu_k \leq \tan\theta = \tan 18° = 0.325$$

Because $\mu_k = 0.40 > \tan 18°$, the block will not move unless pushed.

Because $\mu_k = 0.2$, this condition is satisfied and:

$$m_{min} = 0$$

To find the maximum value, note that the maximum possible value for the tension in the rope is mg. For the block to move down the incline, the component of the block's weight parallel to the incline minus the frictional force must be greater than or equal to the tension in the rope:

$$Mg\sin\theta - \mu_k Mg\cos\theta \geq mg$$

Solving for m_{max} yields:

$$m_{max} \leq M(\sin\theta - \mu_k\cos\theta)$$

Substitute numerical values and evaluate m_{max}:

$$m_{max} \leq (100\,\text{kg})[\sin 18° - (0.20)\cos 18°]$$
$$= 11.9\,\text{kg}$$

The range of values for m is: $\boxed{0 \le m \le 12\,\text{kg}}$

(b) If the block is being dragged up the incline, the frictional force will point down the incline, and:

$$Mg\sin\theta + \mu_k Mg\cos\theta < m_{\min} g$$

Solve for $m_{\min}$:

$$m_{\min} > M(\sin\theta + \mu_k \cos\theta)$$

Substitute numerical values and evaluate $m_{\min}$:

$$m_{\min} > (100\,\text{kg})[\sin 18° + (0.20)\cos 18°] = 49.9\,\text{kg}$$

If the block is not to move unless pushed:

$$Mg\sin\theta + \mu_s Mg\cos\theta > m_{\max} g$$

Solve for $m_{\max}$:

$$m_{\max} < M(\sin\theta + \mu_s \cos\theta)$$

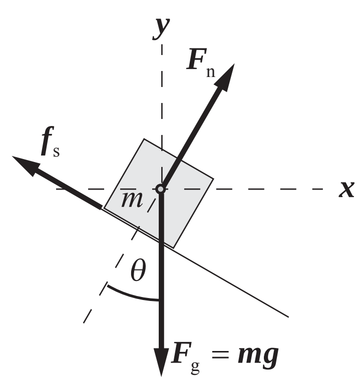
Substitute numerical values and evaluate $m_{\max}$:

$$m_{\max} < (100\,\text{kg})[\sin 18° + (0.40)\cos 18°] = 68.9\,\text{kg}$$

The range of values for m is: $\boxed{50\,\text{kg} \le m \le 69\,\text{kg}}$

63 ••• A block of mass 0.50 kg rests on the inclined surface of a wedge of mass 2.0 kg, as in Figure 5-71. The wedge is acted on by a horizontal applied force $\vec{F}$ and slides on a frictionless surface. (a) If the coefficient of static friction between the wedge and the block is $\mu_s = 0.80$ and the wedge is inclined 35º with the horizontal, find the maximum and minimum values of the applied force for which the block does not slip. (b) Repeat part (a) with $\mu_s = 0.40$.

Picture the Problem The free-body diagram shows the forces acting on the 0.50-kg block when the acceleration is a minimum. Note the choice of coordinate system that is consistent with the direction of $\vec{F}$. Apply Newton's second law to the block and to the block-plus-incline and solve the resulting equations for $F_{\min}$ and $F_{\max}$.



(*a*) The maximum and minimum values of the applied force for which the block does not slip are related to the maximum and minimum accelerations of the block:

$$F_{max} = m_{tot} a_{x,max} \quad (1)$$

and

$$F_{min} = m_{tot} a_{x,min} \quad (2)$$

where m_{tot} is the combined mass of the block and incline.

Apply $\sum \vec{F} = m\vec{a}$ to the 0.50-kg block:

$$\sum F_x = F_n \sin\theta - f_s \cos\theta = ma_x \quad (3)$$

and

$$\sum F_y = F_n \cos\theta + f_s \sin\theta - mg = 0 \quad (4)$$

Under minimum acceleration, $f_s = f_{s,\,max}$. Express the relationship between $f_{s,\,max}$ and F_n:

$$f_{s,max} = \mu_s F_n$$

Substitute $f_{s,\,max}$ for f_s in equation (4) and solve for F_n:

$$F_n = \frac{mg}{\cos\theta + \mu_s \sin\theta}$$

Substitute for F_n and $f_{s,\,max}$ in equation (3) and solve for $a_x = a_{x,min}$:

$$a_{x,min} = g\frac{\sin\theta - \mu_s \cos\theta}{\cos\theta + \mu_s \sin\theta}$$

Substitute for $a_{x,\,min}$ in equation (2) to obtain:

$$F_{min} = m_{tot} g \left(\frac{\sin\theta - \mu_s \cos\theta}{\cos\theta + \mu_s \sin\theta}\right)$$

Substitute numerical values and evaluate F_{min}:

$$F_{min} = \left|(2.5\text{ kg})(9.81\text{ m/s}^2)\left[\frac{\sin 35° - (0.80)\cos 35°}{\cos 35° + (0.80)\sin 35°}\right]\right| = \boxed{1.6\text{ N}}$$

To find the maximum acceleration, reverse the direction of $\vec{f}_s$ and apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\sum F_x = F_n \sin\theta + f_s \cos\theta = ma_x$$

and

$$\sum F_y = F_n \cos\theta - f_s \sin\theta - mg = 0$$

Proceed as above to obtain:

$$a_{x,max} = g\left(\frac{\sin\theta + \mu_s \cos\theta}{\cos\theta - \mu_s \sin\theta}\right)$$

Substitute for $a_{x,\,max}$ in equation (1) to obtain:

$$F_{max} = m_{tot} g \left(\frac{\sin\theta + \mu_s \cos\theta}{\cos\theta - \mu_s \sin\theta}\right)$$

Substitute numerical values and evaluate $F_{\max}$:

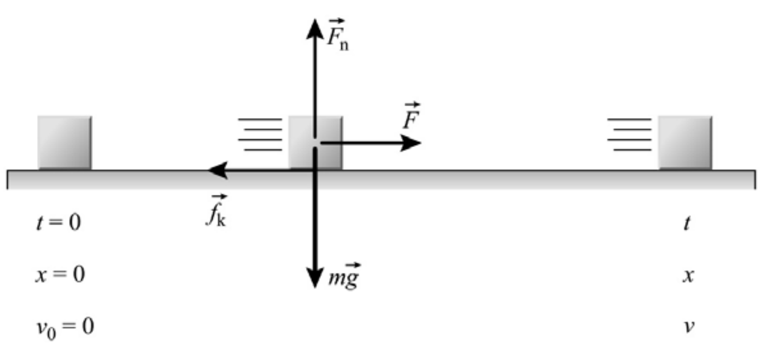
$$F_{\max} = (2.5\ \text{kg})(9.81\ \text{m/s}^2)\left[\frac{\sin 35° + (0.80)\cos 35°}{\cos 35° - (0.80)\sin 35°}\right] = \boxed{84\ \text{N}}$$

(*b*) Repeat Part (*a*) with $\mu_s = 0.40$ to obtain:

$$F_{\min} = \boxed{5.8\ \text{N}} \text{ and } F_{\max} = \boxed{37\ \text{N}}$$

64 ••• In your physics lab, you and your lab partners push a block of wood with a mass of 10.0 kg (starting from rest), with a constant horizontal force of 70 N across a wooden floor. In the previous week's laboratory meeting, your group determined that the coefficient of kinetic friction was not exactly constant, but instead was found to vary with the object's speed according to $\mu_k = 0.11/(1 + 2.3 \times 10^{-4}\, v^2)^2$. Write a **spreadsheet** program using Euler's method to calculate and graph both the speed and the position of the block as a function of time from 0 to 10 s. Compare this result to the result you would get if you assumed the coefficient of kinetic friction had a constant value of 0.11.

Picture the Problem The kinetic friction force f_k is the product of the coefficient of sliding friction μ_k and the normal force F_n the surface exerts on the sliding object. By applying Newton's second law in the vertical direction, we can see that, on a horizontal surface, the normal force is the weight of the sliding object. We can apply Newton's second law in the horizontal (x) direction to relate the block's acceleration to the net force acting on it. In the spreadsheet program, we'll find the acceleration of the block from this net force (which is speed dependent), calculate the increase in the block's speed from its acceleration and the elapsed time and add this increase to its speed at end of the previous time interval, determine how far it has moved in this time interval, and add this distance to its previous position to find its current position. We'll also calculate the position of the block x_2, under the assumption that $\mu_k = 0.11$, using a constant-acceleration equation.



The spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
C9	C8+$B$6	$t+\Delta t$
D9	D8+F9*$B$6	$v+a\Delta t$
E9	$B$5−($B$3)*($B$2)*$B$5/ (1+$B$4*D9^2)^2	$F-\dfrac{\mu_k mg}{\left(1+2.34\times10^{-4}v^2\right)^2}$

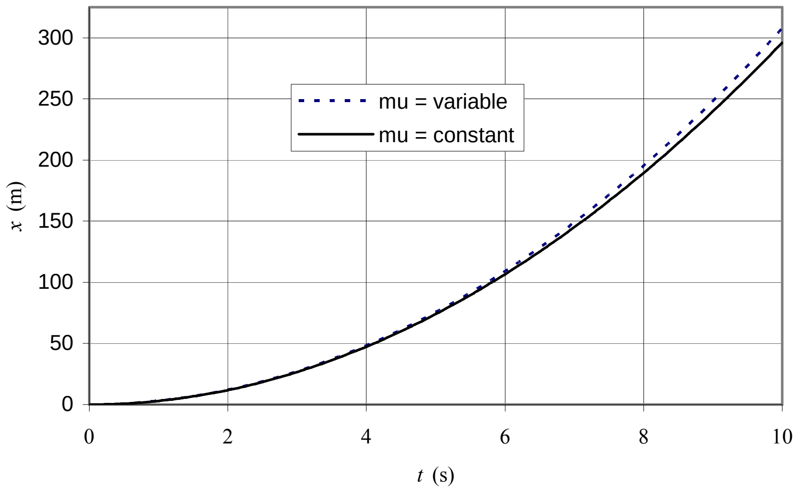
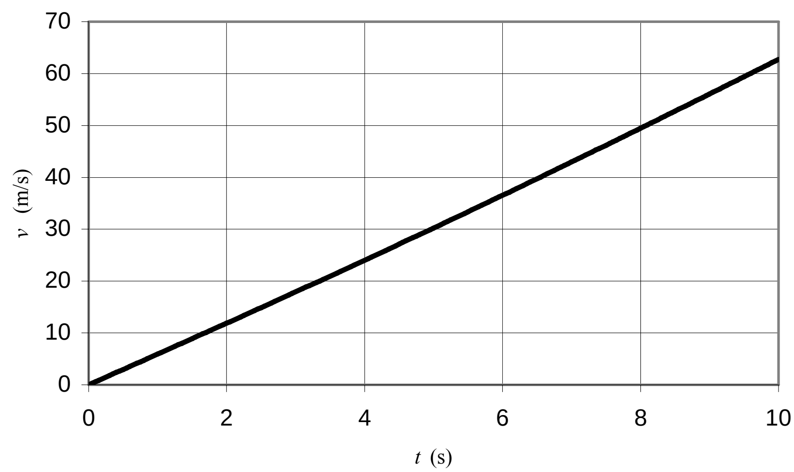
The position of the block as a function of time, for a constant coefficient of friction ($\mu_k = 0.11$) is shown as a solid line on the following graph and for a variable coefficient of friction, is shown as a dotted line. Because the coefficient of friction decreases with increasing particle speed, the particle travels slightly farther when the coefficient of friction is variable.

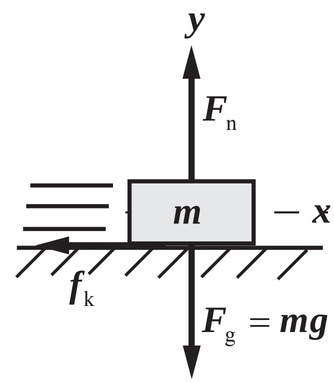


The speed of the block as a function of time, with variable coefficient of kinetic friction, is shown in the following graph.



65 ••• In order to determine the coefficient of kinetic friction of a block of wood on a horizontal table surface, you are given the following assignment: Take the block of wood and give it an initial velocity across the surface of the table. Using a stopwatch, measure the time Δt it takes for the block to come to a stop and the total displacement Δx the block slides following the push. (*a*) Using Newton's laws and a free-body diagram of the block, show that the expression for the coefficient of kinetic friction is given by $\mu_k = 2\Delta x/[(\Delta t)^2 g]$. (*b*) If the block slides a distance of 1.37 m in 0.97 s, calculate μ_k. (*c*) What was the initial speed of the block?

Picture the Problem The free-body diagram shows the forces acting on the block as it moves to the right. The kinetic friction force will slow the block and, eventually, bring it to rest. We can relate the coefficient of kinetic friction to the stopping time and distance by applying Newton's second law and then using constant-acceleration equations.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the block of wood:

$$\sum F_x = -f_k = ma_x$$

and

$$\sum F_y = F_n - mg = 0$$

Using the definition of f_k, eliminate F_n between the two equations to obtain:

$$a_x = -\mu_k g \qquad (1)$$

Use a constant-acceleration equation to relate the acceleration of the block to its displacement and its stopping time:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2 \qquad (2)$$

Relate the initial speed of the block, v_0, to its displacement and stopping distance:

$$\Delta x = v_{av}\Delta t = \left(\frac{v_{0x} + v}{2}\right)\Delta t$$

or, because $v = 0$,

$$\Delta x = \tfrac{1}{2}v_{0x}\Delta t \qquad (3)$$

Use this result to eliminate v_{0x} in equation (2):

$$\Delta x = -\tfrac{1}{2}a_x(\Delta t)^2 \qquad (4)$$

Substitute equation (1) in equation (4) and solve for μ_k:

$$\mu_k = \boxed{\frac{2\Delta x}{g(\Delta t)^2}}$$

(*b*) Substitute for $\Delta x = 1.37$ m and $\Delta t = 0.97$ s to obtain:

$$\mu_k = \frac{2(1.37\,\text{m})}{(9.81\,\text{m/s}^2)(0.97\,\text{s})^2} = \boxed{0.30}$$

(*c*) Use equation (3) to find v_0:

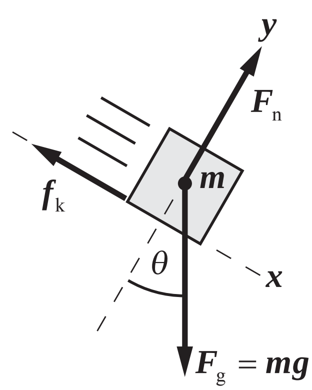
$$v_0 = \frac{2\Delta x}{\Delta t} = \frac{2(1.37\,\text{m})}{0.97\,\text{s}} = \boxed{2.8\,\text{m/s}}$$

66 ••• (*a*) A block is sliding down an inclined plane. The coefficient of kinetic friction between the block and the plane is μ_k. Show that a graph of $a_x/\cos\theta$ versus $\tan\theta$ (where a_x is the acceleration down the incline and θ is the angle the plane is inclined with the horizontal) would be a straight line with slope g and intercept $-\mu_k g$. (*b*) The following data show the acceleration of a block sliding down an inclined plane as a function of the angle θ that the plane is inclined with the horizontal:

θ (degrees)	Acceleration (m/s^2)
25.0	1.69
27.0	2.10
29.0	2.41
31.0	2.89
33.0	3.18
35.0	3.49
37.0	3.79
39.0	4.15
41.0	4.33
43.0	4.72
45.0	5.11

Using a **spreadsheet** program, graph these data and fit a straight line (a Trendline in Excel parlance) to them to determine μ_k and g. What is the percentage difference between the obtained value of g and the commonly specified value of 9.81 m/s^2?

Picture the Problem The free-body diagram shows the forces acting on the block as it slides down an incline. We can apply Newton's second law to these forces to obtain the acceleration of the block and then manipulate this expression algebraically to show that a graph of $a/\cos\theta$ versus $\tan\theta$ will be linear with a slope equal to the acceleration due to gravity and an intercept whose absolute value is the coefficient of kinetic friction.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the block as it slides down the incline:

$$\sum F_x = mg\sin\theta - f_k = ma_x$$

and

$$\sum F_y = F_n - mg\cos\theta = 0$$

Substitute $\mu_k F_n$ for f_k and eliminate F_n between the two equations to obtain:

$$a_x = g(\sin\theta - \mu_k \cos\theta)$$

Divide both sides of this equation by $\cos\theta$ to obtain:

$$\frac{a_x}{\cos\theta} = \boxed{g\tan\theta - g\mu_k}$$

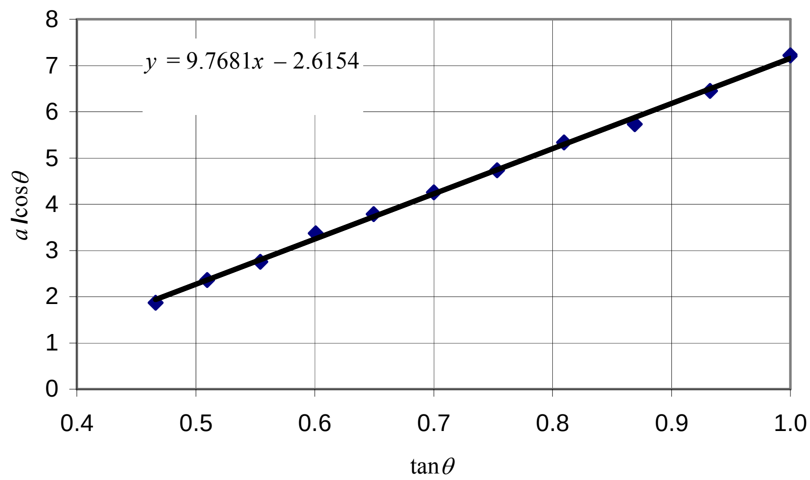
Note that this equation is of the form $y = mx + b$. Thus, if we graph $a/\cos\theta$ versus $\tan\theta$, we should get a straight line with slope g and y-intercept $-g\mu_k$.

(*b*) A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
C7	θ	
D7	a	
E7	TAN(C7*PI()/180)	$\tan\left(\theta\times\frac{\pi}{180}\right)$
F7	D7/COS(C7*PI()/180)	$\frac{a}{\cos\left(\theta\times\frac{\pi}{180}\right)}$

	C	D	E	F
6	θ	a	$\tan\theta$	$a/\cos\theta$
7	25.0	1.69	0.466	1.866
8	27.0	2.10	0.510	2.362
9	29.0	2.41	0.554	2.751
10	31.0	2.89	0.601	3.370
11	33.0	3.18	0.649	3.786
12	35.0	3.49	0.700	4.259
13	37.0	3.78	0.754	4.735
14	39.0	4.15	0.810	5.338
15	41.0	4.33	0.869	5.732
16	43.0	4.72	0.933	6.451
17	45.0	5.11	1.000	7.220

A graph of $a/\cos\theta$ versus $\tan\theta$ follows. From the curve fit (Excel's Trendline was used), $g = \boxed{9.77\ \text{m/s}^2}$ and $\mu_k = \dfrac{2.62\ \text{m/s}^2}{9.77\ \text{m/s}^2} = \boxed{0.268}$.



The percentage error in g from the commonly accepted value of $9.81\ \text{m/s}^2$ is:

$$100\left(\frac{9.81\ \text{m/s}^2 - 9.77\ \text{m/s}^2}{9.81\ \text{m/s}^2}\right) = \boxed{0.408\%}$$

Drag Forces

67 • **[SSM]** A Ping-Pong ball has a mass of 2.3 g and a terminal speed of 9.0 m/s. The drag force is of the form bv^2. What is the value of b?

Picture the Problem The ping-pong ball experiences a downward gravitational force exerted by Earth and an upward drag force exerted by the air. We can apply Newton's second law to the Ping-Pong ball to obtain its equation of motion. Applying terminal speed conditions will yield an expression for b that we can evaluate using the given numerical values. Let the downward direction be the $+y$ direction.

Apply $\sum F_y = ma_y$ to the Ping-Pong ball:

$$mg - bv^2 = ma_y$$

When the Ping-Pong ball reaches its terminal speed $v = v_t$ and $a_y = 0$:

$$mg - bv_t^2 = 0 \Rightarrow b = \frac{mg}{v_t^2}$$

Substitute numerical values and evaluate b:

$$b = \frac{\left(2.3\times10^{-3}\ \text{kg}\right)\left(9.81\,\text{m/s}^2\right)}{\left(9.0\,\text{m/s}\right)^2} = \boxed{2.8\times10^{-4}\ \text{kg/m}}$$

68 • A small pollution particle settles toward Earth in still air. The terminal speed is 0.30 mm/s, the mass of the particle is 1.0 × 10^{-10} g and the drag force is of the form bv. What is the value of b?

Picture the Problem The pollution particle experiences a downward gravitational force exerted by Earth and an upward drag force exerted by the air. We can apply Newton's second law to the particle to obtain its equation of motion. Applying terminal speed conditions will yield an expression for b that we can evaluate using the given numerical values. Let the downward direction by the $+y$ direction.

Apply $\sum F_y = ma_y$ to the particle:

$$mg - bv = ma_y$$

When the particle reaches its terminal speed $v = v_t$ and $a_y = 0$:

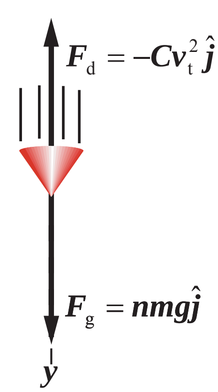
$$mg - bv_t = 0 \Rightarrow b = \frac{mg}{v_t}$$

Substitute numerical values and evaluate b:

$$b = \frac{\left(1.0\times10^{-13}\,\text{kg}\right)\left(9.81\,\text{m/s}^2\right)}{3.0\times10^{-4}\ \text{m/s}} = \boxed{3.3\times10^{-9}\ \text{kg/s}}$$

69 •• **[SSM]** A common classroom demonstration involves dropping basket-shaped coffee filters and measuring the time required for them to fall a given distance. A professor drops a single basket-shaped coffee filter from a height h above the floor, and records the time for the fall as Δt. How far will a stacked set of n identical filters fall during the same time interval Δt? Consider the filters to be so light that they instantaneously reach their terminal velocities. Assume a drag force that varies as the square of the speed and assume the filters are released oriented right-side up.

Picture the Problem The force diagram shows n coffee filters experiencing an upward drag force exerted by the air that varies with the square of their terminal velocity and a downward gravitational force exerted by Earth. We can use the definition of average velocity and Newton's second law to establish the dependence of the distance of fall on n.



Express the distance fallen by 1 coffee filter, falling at its terminal speed, in time Δt:

$$d_{1\text{ filter}} = v_{\text{t, 1 filter}}\Delta t \qquad (1)$$

Express the distance fallen by n coffee filters, falling at their terminal speed, in time Δt:

$$d_{n\text{ filters}} = v_{\text{t, }n\text{ filters}}\Delta t \qquad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{d_{n\text{ filters}}}{d_{1\text{ filter}}} = \frac{v_{\text{t, }n\text{ filters}}\Delta t}{v_{\text{t, 1 filter}}\Delta t} = \frac{v_{\text{t, }n\text{ filters}}}{v_{\text{t, 1 filter}}}$$

Solving for $d_{n\text{ filters}}$ yields:

$$d_{n\text{ filters}} = \left(\frac{v_{\text{t, }n\text{ filters}}}{v_{\text{t, 1 filter}}}\right)d_{1\text{ filter}} \qquad (3)$$

Apply $\sum F_y = ma_y$ to the coffee filters:

$$nmg - Cv_\text{t}^2 = ma_y$$

or, because $a_y = 0$,

$$nmg - Cv_\text{t}^2 = 0$$

Solving for v_t yields:

$$v_{\text{t, }n\text{ filters}} = \sqrt{\frac{nmg}{C}} = \sqrt{\frac{mg}{C}}\sqrt{n}$$

or, because $v_{\text{t, 1 filter}} = \sqrt{\frac{mg}{C}}$,

$$v_{\text{t, }n\text{ filters}} = v_{\text{t, 1 filter}}\sqrt{n}$$

Substitute for $v_{\text{t, }n\text{ filters}}$ in equation (3) to obtain:

$$d_{n\text{ filters}} = \left(\frac{v_{\text{t, 1 filter}}\sqrt{n}}{v_{\text{t, 1 filter}}}\right)d_{1\text{ filter}} = \boxed{\sqrt{n}\,d_{1\text{ filter}}}$$

This result tells us that n filters will fall farther, in the same amount of time, than 1 filter by a factor of $\sqrt{n}$.

70 •• A skydiver of mass 60.0 kg can slow herself to a constant speed of 90 km/h by orienting her body horizontally, looking straight down with arms and legs extended. In this position she presents the maximum cross-sectional area and thus maximizes the air-drag force on her. (*a*) What is the magnitude of the drag force on the skydiver? (*b*) If the drag force is given by bv^2, what is the value of b? (*c*) At some instant she quickly flips into a ″knife″ position, orienting her body vertically with her arms straight down. Suppose this reduces the value of b to 55 percent of the value in Parts (*a*) and (*b*). What is her acceleration at the instant she achieves the ″knife″ position?

Picture the Problem The skydiver experiences a downward gravitational force exerted by Earth and an upward drag force exerted by the air. Let the upward direction be the $+y$ direction and apply Newton's second law to the sky diver.

(*a*) Apply $\sum F_y = ma_y$ to the sky diver:

$$F_d - mg = ma_y \tag{1}$$

or, because $a_y = 0$,

$$F_d = mg \tag{2}$$

Substitute numerical values and evaluate F_d:

$$F_d = (60.0\,\text{kg})(9.81\,\text{m/s}^2) = 588.6\,\text{N} = \boxed{589\,\text{N}}$$

(*b*) Substitute $F_d = bv_t^2$ in equation (2) to obtain:

$$bv_t^2 = mg \Rightarrow b = \frac{mg}{v_t^2} = \frac{F_d}{v_t^2}$$

Substitute numerical values and evaluate b:

$$b = \frac{588.6\,\text{N}}{\left(90\,\frac{\text{km}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)^2} = 0.9418\,\text{kg/m} = \boxed{0.94\,\text{kg/m}}$$

(*c*) Solving equation (1) for a_y yields:

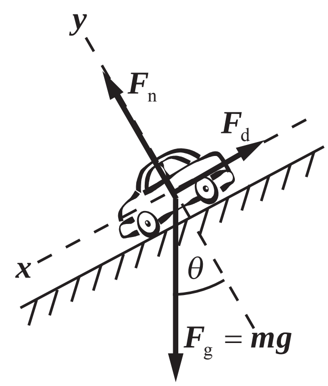
$$a_y = \left|\frac{F_d}{m} - g\right|$$

Because b is reduced to 55 percent of its value in Part (*b*), so is F_d. Substitute numerical values and evaluate a_y:

$$a_y = \left|\frac{(0.55)(588.6\,\text{N})}{60.0\,\text{kg}} - 9.81\,\text{m/s}^2\right| = \boxed{4.41\,\text{m/s}^2\text{, downward}}$$

71 •• Your team of test engineers is to release the parking brake so an 800-kg car will roll down a very long 6.0% grade in preparation for a crash test at the bottom of the incline. (On a 6.0 % grade the change in altitude is 6.0% of the horizontal distance traveled.) The total resistive force (air drag plus rolling friction) for this car has been previously established to be F_d = 100 N + (1.2 N·s^2/m^2)v^2, where m and v are the mass and speed of the car. What is the terminal speed for the car rolling down this grade?

Picture the Problem The free-body diagram shows the forces acting on the car as it descends the grade with its terminal speed and a convenient coordinate system. The application of Newton's second law with $a = 0$ and F_d equal to the given function will allow us to solve for the terminal speed of the car.



Apply $\sum F_x = ma_x$ to the car:

$$mg\sin\theta - F_d = ma_x$$

or, because $v = v_t$ and $a_x = 0$,

$$mg\sin\theta - F_d = 0$$

Substitute for F_d to obtain:

$$mg\sin\theta - 100\,\text{N} - \left(1.2\,\text{N}\cdot\text{s}^2/\text{m}^2\right)v_t^2 = 0$$

Solving for v_t yields:

$$v_t = \sqrt{\frac{mg\sin\theta - 100\,\text{N}}{1.2\,\text{N}\cdot\text{s}^2/\text{m}^2}}$$

Substitute numerical values and evaluate v_t:

$$v_t = \sqrt{\frac{(800\,\text{kg})\left(9.81\,\text{m/s}^2\right)\sin 6.0° - 100\,\text{N}}{1.2\,\text{N}\cdot\text{s}^2/\text{m}^2}} = \boxed{25\,\text{m/s}}$$

72 ••• Small slowly moving spherical particles experience a drag force given by Stokes' law: $F_d = 6\pi\eta rv$, where r is the radius of the particle, v is its speed, and η is the coefficient of viscosity of the fluid medium. (*a*) Estimate the terminal speed of a spherical pollution particle of radius 1.00×10^{-5} m and density of 2000 kg/m^3. (*b*) Assuming that the air is still and that η is 1.80×10^{-5} N·s/m^2, estimate the time it takes for such a particle to fall from a height of 100 m.

Picture the Problem Let the downward direction be the +y direction and apply Newton's second law to the particle to obtain an equation from which we can find the particle's terminal speed.

(*a*) Apply $\sum F_y = ma_y$ to a pollution particle:

$$mg - 6\pi\eta rv = ma_y$$

or, because $a_y = 0$,

$$mg - 6\pi\eta rv_t = 0 \Rightarrow v_t = \frac{mg}{6\pi\eta r}$$

Express the mass of a sphere in terms of its volume:

$$m = \rho V = \rho\left(\frac{4\pi r^3}{3}\right)$$

Substitute for m to obtain:

$$v_t = \frac{2r^2\rho g}{9\eta}$$

Substitute numerical values and evaluate v_t:

$$v_t = \frac{2(1.00\times10^{-5}\ \text{m})^2(2000\,\text{kg/m}^3)(9.81\,\text{m/s}^2)}{9(1.80\times10^{-5}\ \text{N}\cdot\text{s/m}^2)} = 2.422\ \text{cm/s} = \boxed{2.42\,\text{cm/s}}$$

(*b*) Use distance equals average speed times the fall time to find the time to fall 100 m at 2.42 cm/s:

$$t = \frac{10^4\ \text{cm}}{2.422\,\text{cm/s}} = 4.128\times10^3\ \text{s} = \boxed{1.15\,\text{h}}$$

73 ••• [SSM] You are on an environmental chemistry internship, and are in charge of a sample of air that contains pollution particles of the size and density given in Problem 72. You capture the sample in an 8.0-cm-long test tube. You then place the test tube in a centrifuge with the midpoint of the test tube 12 cm from the center of the centrifuge. You set the centrifuge to spin at 800 revolutions per minute. (*a*) Estimate the time you have to wait so that nearly all of the pollution particles settle to the end of the test tube. (*b*) Compare this to the time required for a pollution particle to fall 8.0 cm under the action of gravity and subject to the drag force given in Problem 72.

Picture the Problem The motion of the centrifuge will cause the pollution particles to migrate to the end of the test tube. We can apply Newton's second law and Stokes' law to derive an expression for the terminal speed of the sedimentation particles. We can then use this terminal speed to calculate the sedimentation time. We'll use the 12 cm distance from the center of the centrifuge as the average radius of the pollution particles as they settle in the test tube. Let *R* represent the radius of a particle and *r* the radius of the particle's circular path in the centrifuge.

(*a*) Express the sedimentation time in terms of the sedimentation speed v_t:

$$\Delta t_{\text{sediment}} = \frac{\Delta x}{v_t} \qquad (1)$$

Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to a pollution particle:

$$6\pi\eta R v_t = ma_c$$

Express the mass of the particle in terms of its radius R and density ρ:

$$m = \rho V = \tfrac{4}{3}\pi R^3 \rho$$

Express the acceleration of the pollution particles due to the motion of the centrifuge in terms of their orbital radius r and period T:

$$a_c = \frac{v^2}{r} = \frac{\left(\dfrac{2\pi r}{T}\right)^2}{r} = \frac{4\pi^2 r}{T^2}$$

Substitute for m and a_c and simplify to obtain:

$$6\pi\eta R v_t = \tfrac{4}{3}\pi R^3 \rho\left(\frac{4\pi^2 r}{T^2}\right) = \frac{16\pi^3 \rho r R^3}{3T^2}$$

Solving for v_t yields:

$$v_t = \frac{8\pi^2 \rho r R^2}{9\eta T^2}$$

Substitute for v_t in equation (1) and simplify to obtain:

$$\Delta t_{\text{sediment}} = \frac{\Delta x}{\dfrac{8\pi^2 \rho r R^2}{9\eta T^2}} = \frac{9\eta T^2 \Delta x}{8\pi^2 \rho r R^2}$$

Substitute numerical values and evaluate $\Delta t_{\text{sediment}}$:

$$\Delta t_{\text{sediment}} = \frac{9\left(1.8\times10^{-5}\,\dfrac{\text{N}\cdot\text{s}}{\text{m}^2}\right)\left(\dfrac{1}{800\,\dfrac{\text{rev}}{\text{min}}\cdot\dfrac{1\,\text{min}}{60\,\text{s}}}\right)^2 (8.0\,\text{cm})}{8\pi^2\left(2000\,\dfrac{\text{kg}}{\text{m}^3}\right)(0.12\,\text{m})\left(10^{-5}\,\text{m}\right)^2} = 38.47\text{ ms} \approx \boxed{38\text{ ms}}$$

(*b*) In Problem 72 it was shown that the rate of fall of the particles in air is 2.42 cm/s. Find the time required to fall 8.0 cm in air under the influence of gravity:

$$\Delta t_{\text{air}} = \frac{\Delta x}{v} = \frac{8.0\,\text{cm}}{2.42\,\text{cm/s}} = 3.31\,\text{s}$$

Find the ratio of the two times:

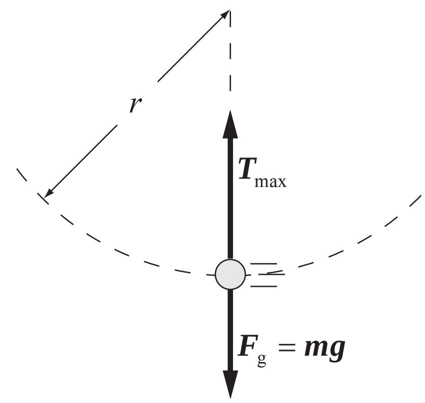
$$\frac{\Delta t_{\text{air}}}{\Delta t_{\text{sediment}}} = \frac{3.31\,\text{s}}{38.47\,\text{ms}} \approx 86$$

With the drag force in Problem 72 it takes about 86 times longer than it does using the centrifuge.

Motion Along a Curved Path

74 • A rigid rod with a 0.050-kg ball at one end rotates about the other end so the ball travels at constant speed in a vertical circle with a radius of 0.20 m. What is the maximum speed of the ball so that the force of the rod on the ball does not exceed 10 N?

Picture the Problem The force of the rod on the ball is a maximum when the ball is at the bottom of the vertical circle. We can use Newton's second law to relate the force of the rod on the ball to the mass *m* of the ball, the radius *r* of its path, and the constant speed of the ball along its circular path. The diagram to the right shows the forces acting on the ball when it is at the bottom of the vertical circle.



Apply $\sum F_{radial} = ma_{radial}$ to the ball:

$$T_{max} - mg = m\frac{v_{max}^2}{r}$$

Solving for v_{max} yields:

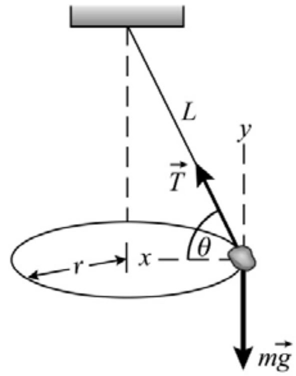
$$v_{max} = \sqrt{\left(\frac{T_{max}}{m} - g\right)r}$$

Substitute numerical values and evaluate v_{max}:

$$v_{max} = \sqrt{\left(\frac{10\ \text{N}}{0.050\ \text{kg}} - 9.81\ \text{m/s}^2\right)(0.20\ \text{m})} = \boxed{6.2\ \text{m/s}}$$

75 • **[SSM]** A 95-g stone is whirled in a horizontal circle on the end of an 85-cm-long string. The stone takes 1.2 s to make one complete revolution. Determine the angle that the string makes with the horizontal.

Picture the Problem The only forces acting on the stone are the tension in the string and the gravitational force. The centripetal force required to maintain the circular motion is a component of the tension. We'll solve the problem for the general case in which the angle with the horizontal is θ by applying Newton's second law of motion to the forces acting on the stone.



Apply $\sum \vec{F} = m\vec{a}$ to the stone:

$$\sum F_x = T\cos\theta = ma_c = m\frac{v^2}{r} \quad (1)$$

and

$$\sum F_y = T\sin\theta - mg = 0 \quad (2)$$

Use the right triangle in the diagram to relate r, L, and θ:

$$r = L\cos\theta \quad (3)$$

Eliminate T and r between equations (1), (2) and (3) and solve for v_2:

$$v^2 = gL\cot\theta\cos\theta \quad (4)$$

Express the speed of the stone in terms of its period:

$$v = \frac{2\pi r}{t_{1\,\text{rev}}} \quad (5)$$

Eliminate v between equations (4) and (5) and solve for θ:

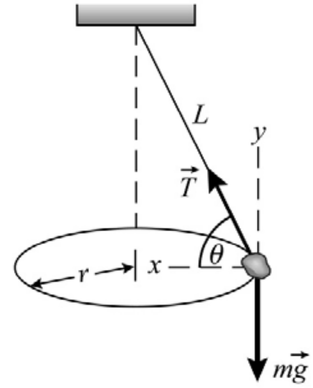
$$\theta = \sin^{-1}\left(\frac{gt_{1\,\text{rev}}^2}{4\pi^2 L}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{(9.81\,\text{m/s}^2)(1.2\,\text{s})^2}{4\pi^2(0.85\,\text{m})}\right] = \boxed{25°}$$

76 •• A 0.20-kg stone is whirled in a horizontal circle on the end of an 0.80-m-long string. The string makes an angle of 20º with the horizontal. Determine the speed of the stone.

Picture the Problem The only forces acting on the stone as it moves in a horizontal circle are the tension in the string and the gravitational force. The centripetal force required to maintain the circular motion is a component of the tension. We'll solve the problem for the general case in which the angle with the horizontal is θ by applying Newton's second law of motion to the forces acting on the stone.



Apply $\sum \vec{F} = m\vec{a}$ to the stone:

$$\sum F_x = T\cos\theta = ma_c = m\frac{v^2}{r} \quad (1)$$

and

$$\sum F_y = T\sin\theta - mg = 0 \quad (2)$$

Use the right triangle in the diagram to relate r, L, and θ:

$$r = L\cos\theta \quad (3)$$

Eliminate T and r between equations (1), (2), and (3) and solve for v:

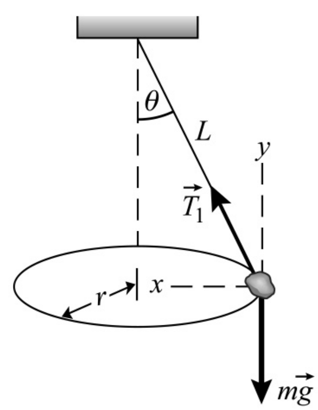
$$v = \sqrt{gL\cot\theta\cos\theta}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(9.81\,\text{m/s}^2)(0.80\,\text{m})\cot 20°\cos 20°} = \boxed{4.5\,\text{m/s}}$$

77 •• A 0.75-kg stone attached to a string is whirled in a horizontal circle of radius 35 cm as in the tetherball Example 5-11. The string makes an angle of 30º with the vertical. (*a*) Find the speed of the stone. (*b*) Find the tension in the string.

Picture the Problem The only forces acting on the stone are the tension in the string and the gravitational force. The centripetal force required to maintain the circular motion is a component of the tension. We'll solve the problem for the general case in which the angle with the vertical is θ by applying Newton's second law of motion to the forces acting on the stone.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the stone:

$$\sum F_x = T\sin\theta = ma_c = m\frac{v^2}{r} \quad (1)$$

and

$$\sum F_y = T\cos\theta - mg = 0 \quad (2)$$

Eliminate T between equations (1) and (2) and solve for v:

$$v = \sqrt{rg\tan\theta}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(0.35\,\text{m})(9.81\,\text{m/s}^2)\tan 30°} = \boxed{1.4\,\text{m/s}}$$

(*b*) Solving equation (2) for T yields:

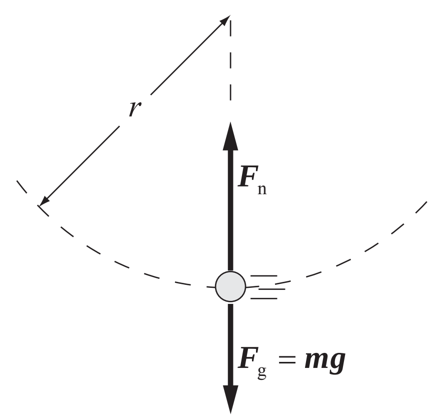
$$T = \frac{mg}{\cos\theta}$$

Substitute numerical values and evaluate T:

$$T = \frac{(0.75\,\text{kg})(9.81\,\text{m/s}^2)}{\cos 30°} = \boxed{8.5\,\text{N}}$$

78 •• A pilot with a mass of 50 kg comes out of a vertical dive in a circular arc such that at the bottom of the arc her upward acceleration is 3.5*g*. (*a*) How does the magnitude of the force exerted by the airplane seat on the pilot at the bottom of the arc compare to her weight? (*b*) Use Newton's laws of motion to explain why the pilot might be subject to a blackout. This means that an above normal volume of blood ″pools″ in her lower limbs. How would an inertial reference frame observer describe the cause of the blood pooling?

Picture the Problem The diagram shows the forces acting on the pilot when her plane is at the lowest point of its dive. $\vec{F}_n$ is the force the airplane seat exerts on her. We'll apply Newton's second law for circular motion to determine F_n and the radius of the circular path followed by the airplane.



(*a*) Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the pilot:

$$F_n - mg = ma_c \Rightarrow F_n = m(g + a_c)$$

Because $a_c = 3.5g$:

$$F_n = m(g + 3.5g) = 4.5mg$$

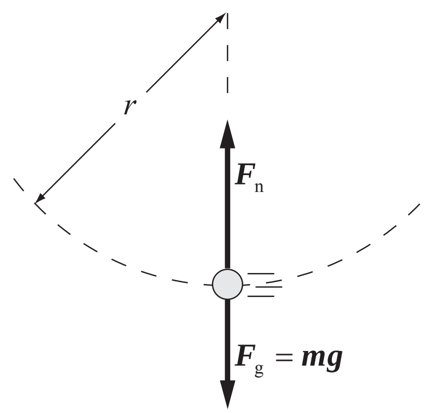
The ratio of F_n to her weight is:

$$\frac{F_n}{mg} = \frac{4.5mg}{mg} = \boxed{4.5}$$

(*b*) An observer in an inertial reference frame would see the pilot's blood continue to flow in a straight line tangent to the circle at the lowest point of the arc. The pilot accelerates upward away from this lowest point and therefore it appears, from the reference frame of the plane, as though the blood accelerates downward.

79 •• A 80.0-kg airplane pilot pulls out of a dive by following, at a constant speed of 180 km/h, the arc of a circle whose radius is 300 m. (*a*) At the bottom of the circle, what are the direction and magnitude of his acceleration? (*b*) What is the net force acting on him at the bottom of the circle? (*c*) What is the force exerted on the pilot by the airplane seat?

Picture the Problem The diagram shows the forces acting on the pilot when his plane is at the lowest point of its dive. $\vec{F}_n$ is the force the airplane seat exerts on the pilot. We'll use the definitions of centripetal acceleration and centripetal force and apply Newton's second law to calculate these quantities and the normal force acting on the pilot.



(*a*) The pilot's acceleration is centripetal and given by:

$$a_c = \frac{v^2}{r}\text{, upward}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{\left(180\,\frac{\text{km}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{300\,\text{m}} = 8.333\,\text{m/s}^2$$

$$= \boxed{8.33\,\text{m/s}^2\text{, upward}}$$

(*b*) The net force acting on her at the bottom of the circle is the force responsible for her centripetal acceleration:

$$F_{net} = ma_c = (80.0\,\text{kg})(8.333\,\text{m/s}^2)$$

$$= \boxed{667\,\text{N, upward}}$$

(*c*) Apply $\sum F_y = ma_y$ to the pilot:

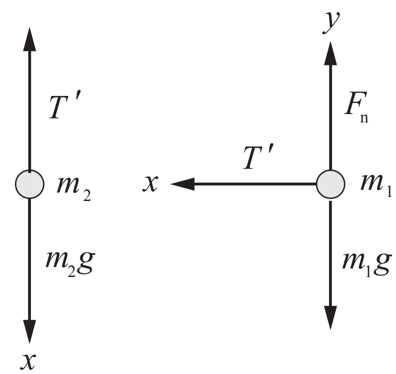
$$F_n - mg = ma_c \Rightarrow F_n = m(g + a_c)$$

Substitute numerical values and evaluate F_n:

$$F_n = (80.0\text{ kg})(9.81\text{ m/s}^2 + 8.33\text{ m/s}^2) = \boxed{1.45\text{ kN, upward}}$$

80 •• A small object of mass m_1 moves in a circular path of radius r on a frictionless horizontal tabletop (Figure 5-72). It is attached to a string that passes through a small frictionless hole in the center of the table. A second object with a mass of m_2 is attached to the other end of the string. Derive an expression for r in terms of m_1, m_2, and the time T for one revolution.

Picture the Problem Assume that the string is massless and that it does not stretch. The free-body diagrams for the two objects are shown to the right. The hole in the table changes the direction the tension in the string (which provides the centripetal force required to keep the object moving in a circular path) acts. The application of Newton's second law and the definition of centripetal force will lead us to an expression for r as a function of m_1, m_2, and the time T for one revolution.



Apply $\sum F_x = ma_x$ to both objects and use the definition of centripetal acceleration to obtain:

$$m_2 g - T' = 0$$

and

$$T' = m_1 a_c = m_1 \frac{v^2}{r}$$

Eliminating T between these equations gives:

$$m_2 g - m_1 \frac{v^2}{r} = 0 \qquad (1)$$

Express the speed v of the object in terms of the distance it travels each revolution and the time T for one revolution:

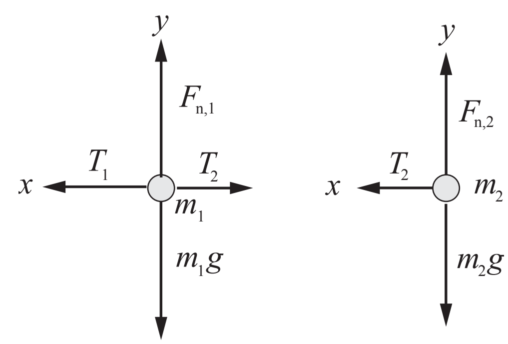
$$v = \frac{2\pi r}{T}$$

Substitute for v in equation (1) to obtain:

$$m_2 g - m_1 \frac{4\pi^2 r}{T^2} = 0 \Rightarrow r = \boxed{\frac{m_2 g T^2}{4\pi^2 m_1}}$$

81 •• **[SSM]** A block of mass m_1 is attached to a cord of length L_1, which is fixed at one end. The block moves in a horizontal circle on a frictionless tabletop. A second block of mass m_2 is attached to the first by a cord of length L_2 and also moves in a circle on the same frictionless tabletop, as shown in Figure 5-73. If the period of the motion is T, find the tension in each cord in terms of the given symbols.

Picture the Problem The free-body diagrams show the forces acting on each block. We can use Newton's second law to relate these forces to each other and to the masses and accelerations of the blocks.



Apply $\sum F_x = ma_x$ to the block whose mass is m_1:

$$T_1 - T_2 = m_1 \frac{v_1^2}{L_1}$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$$T_2 = m_2 \frac{v_2^2}{L_1 + L_2}$$

Relate the speeds of each block to their common period T and their distance from the center of the circle:

$$v_1 = \frac{2\pi L_1}{T} \text{ and } v_2 = \frac{2\pi(L_1 + L_2)}{T}$$

In the second force equation, substitute for v_2, and simplify to obtain:

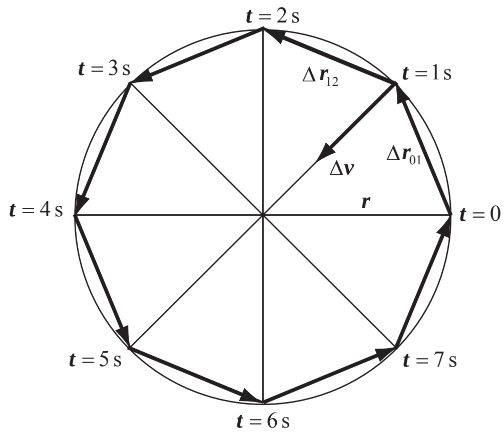
$$T_2 = \boxed{[m_2(L_1 + L_2)]\left(\frac{2\pi}{T}\right)^2}$$

Substitute for T_2 and v_1 in the first force equation to obtain:

$$T_1 = \boxed{[m_2(L_1 + L_2) + m_1L_1]\left(\frac{2\pi}{T}\right)^2}$$

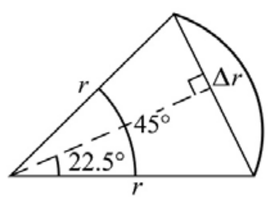
82 •• A particle moves with constant speed in a circle of radius 4.0 cm. It takes 8.0 s to complete each revolution. (*a*) Draw the path of the particle to scale, and indicate the particle's position at 1.0-s intervals. (*b*) Sketch the displacement vectors for each interval. These vectors also indicate the directions for the average-velocity vectors for each interval. (*c*) Graphically find the magnitude of the change in the average velocity $|\Delta\vec{v}|$ for two consecutive 1-s intervals. Compare $|\Delta\vec{v}|/\Delta t$, measured in this way, with the magnitude of the instantaneous acceleration computed from $a_c = v^2/r$.

Picture the Problem (*a*) and (*b*) The path of the particle and its position at 1-s intervals are shown in the following diagram. The displacement vectors are also shown. The velocity vectors for the average velocities in the first and second intervals are along $\vec{r}_{01}$ and $\vec{r}_{12}$, respectively. $\Delta\vec{v}$ points toward the center of the circle.



(*c*) Use the diagram below to show that:

$$\Delta r = 2r\sin 22.5°$$

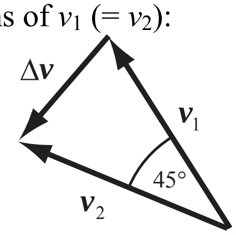


Express the magnitude of the average velocity of the particle along the chords:

$$|\vec{v}_{\text{av}}| = \frac{\Delta r}{\Delta t} = \frac{2r\sin 22.5°}{\Delta t}$$

Using the diagram below, express Δv in terms of v_1 (= v_2):

$$\Delta v = 2v_1 \sin 22.5°$$



Express Δv using v_{av} as v_1:

$$\Delta v = 2\left(\frac{2r\sin 22.5°}{\Delta t}\right)\sin 22.5°$$

$$= \frac{4r\sin^2 22.5°}{\Delta t}$$

Express $a=\dfrac{\Delta v}{\Delta t}$:

$$a=\frac{\dfrac{4r\sin^2 22.5°}{\Delta t}}{\Delta t}=\frac{4r\sin^2 22.5°}{(\Delta t)^2}$$

Substitute numerical values and evaluate a:

$$a=\frac{4(4.0\text{ cm})\sin^2 22.5°}{(1.0\text{ s})^2}=2.34\text{ cm/s}^2$$
$$=\boxed{2.3\text{ cm/s}^2}$$

The radial acceleration of the particle is given by:

$$a_c=\frac{v^2}{r}$$

Express the speed v (= $v_1 = v_2$ …) of the particle along its circular path:

$$v=\frac{2\pi r}{T}$$

Substituting for v in the expression for a_c yields:

$$a_c=\frac{\left(\dfrac{2\pi r}{T}\right)^2}{r}=\frac{4\pi^2 r}{T^2}$$

Substitute numerical values and evaluate a_c:

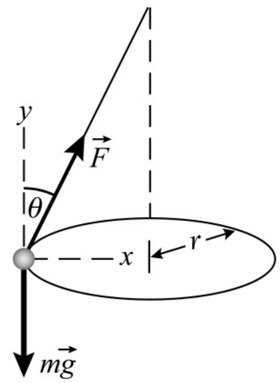
$$a_c=\frac{4\pi^2(4.0\text{ cm})}{(8.0\text{ s})^2}=2.47\text{ cm/s}^2$$
$$=\boxed{2.5\text{ cm/s}^2}$$

Compare a_c and a by taking their ratio:

$$\frac{a_c}{a}=\frac{2.47\text{ cm/s}^2}{2.34\text{ cm/s}^2}=1.06\Rightarrow a_c=\boxed{1.1a}$$

83 •• You are swinging your younger sister in a circle of radius 0.75 m, as shown in Figure 5-74. If her mass is 25 kg and you arrange it so she makes one revolution every 1.5 s, (*a*) what are the magnitude and direction of the force that must be exerted by you on her? (Model her as a point particle.) (*b*) What are the magnitude and direction of the force she exerts on you?

Picture the Problem The following diagram shows the free-body diagram for the child superimposed on a pictorial representation of her motion. The force you exert on your sister is $\vec{F}$ and the angle it makes with respect to the direction we've chosen as the positive y direction is θ. We can infer her speed from the given information concerning the radius of her path and the period of her motion. Applying Newton's second law will allow us to find both the direction and magnitude of $\vec{F}$.



(*a*) Apply $\sum \vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to the child:

$$\sum F_x = F\sin\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F\cos\theta - mg = 0$$

Eliminate *F* between these equations and solve for θ to obtain:

$$\theta = \tan^{-1}\left[\frac{v^2}{rg}\right]$$

Express *v* in terms of the radius and period of the child's motion:

$$v = \frac{2\pi r}{T}$$

Substitute for *v* in the expression for θ to obtain:

$$\theta = \tan^{-1}\left[\frac{4\pi^2 r}{gT^2}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left[\frac{4\pi^2(0.75\,\text{m})}{(9.81\,\text{m/s}^2)(1.5\,\text{s})^2}\right] = 53.3°$$

$$= \boxed{53°}\ \text{above horizontal}$$

Solve the *y* equation for *F*:

$$F = \frac{mg}{\cos\theta}$$

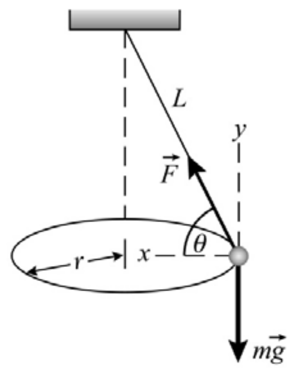
Substitute numerical values and evaluate *F*:

$$F = \frac{(25\,\text{kg})(9.81\,\text{m/s}^2)}{\cos 53.3°} = \boxed{0.41\,\text{kN}}$$

(*b*) The force your sister exerts on you is the reaction force to the force you exert on her. Thus its magnitude is the same as the force you exert on her (0.41 kN) and its direction is 53° below horizontal.

84 •• The string of a conical pendulum is 50.0 cm long and the mass of the bob is 0.25 kg. (*a*) Find the angle between the string and the horizontal when the tension in the string is six times the weight of the bob. (*b*) Under those conditions, what is the period of the pendulum?

Picture the Problem The following diagram shows the free-body diagram for the bob of the conical pendulum superimposed on a pictorial representation of its motion. The tension in the string is $\vec{F}$ and the angle it makes with respect to the direction we've chosen as the +*x* direction is θ. We can find θ from the *y* equation and the information provided about the tension. Then, by using the definition of the speed of the bob in its orbit and applying Newton's second law as it describes circular motion, we can find the period *T* of the motion.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the pendulum bob:

$$\sum F_x = F\cos\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F\sin\theta - mg = 0$$

Using the given information that $F = 6mg$, solve the *y* equation for θ and simplify to obtain:

$$\theta = \sin^{-1}\left(\frac{mg}{F}\right) = \sin^{-1}\left(\frac{mg}{6mg}\right) = \boxed{9.6°}$$

(*b*) With $F = 6mg$, solve the *x* equation for *v*:

$$v = \sqrt{6rg\cos\theta}$$

Relate the period *T* of the motion to the speed of the bob and the radius of the circle in which it moves:

$$T = \frac{2\pi r}{v} = \frac{2\pi r}{\sqrt{6rg\cos\theta}}$$

From the diagram, one can see that:

$$r = L\cos\theta$$

Substitute for r in the expression for the period and simplify to obtain:

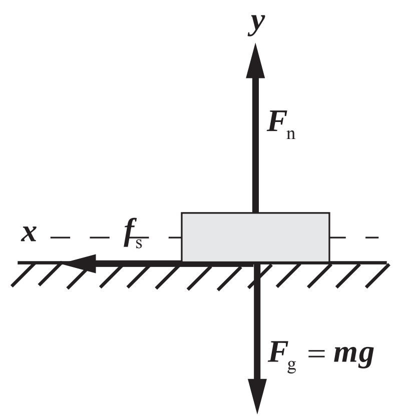
$$T = 2\pi\sqrt{\frac{L}{6g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{0.50\text{ m}}{6\left(9.81\text{ m/s}^2\right)}} = \boxed{0.58\text{ s}}$$

85 •• A 100-g coin sits on a horizontally rotating turntable. The turntable makes exactly 1.00 revolution each second. The coin is located 10 cm from the axis of rotation of the turntable. (*a*) What is the frictional force acting on the coin? (*b*) If the coin slides off the turntable when it is located more than 16.0 cm from the axis of rotation, what is the coefficient of static friction between the coin and the turntable?

Picture the Problem The static friction force f_s is responsible for keeping the coin from sliding on the turntable. Using Newton's second law of motion, the definition of the period of the coin's motion, and the definition of the maximum static friction force, we can find the magnitude of the friction force and the value of the coefficient of static friction for the two surfaces.



(*a*) Apply $\sum\vec{F} = m\vec{a}$ to the coin:

$$\sum F_x = f_s = m\frac{v^2}{r} \qquad (1)$$

and

$$\sum F_y = F_n - mg = 0$$

If T is the period of the coin's motion, its speed is given by:

$$v = \frac{2\pi r}{T}$$

Substitute for v in equation (1) and simplify to obtain:

$$f_s = \frac{4\pi^2 mr}{T^2}$$

Substitute numerical values and evaluate f_s:

$$f_s = \frac{4\pi^2\left((0.100\text{ kg})(0.10\text{ m})\right)}{(1.00\text{ s})^2} = \boxed{0.40\text{ N}}$$

(*b*) Determine F_n from the y equation: $F_n = mg$

If the coin is on the verge of sliding at r = 16 cm, $f_s = f_{s,max}$. Solve for μ_s in terms of $f_{s,max}$ and F_n:

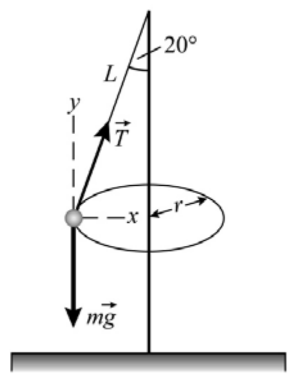
$$\mu_s = \frac{f_{s,max}}{F_n} = \frac{\frac{4\pi^2 mr}{T^2}}{mg} = \frac{4\pi^2 r}{gT^2}$$

Substitute numerical values and evaluate μ_s:

$$\mu_s = \frac{4\pi^2(0.160\,\text{m})}{(9.81\,\text{m/s}^2)(1.00\,\text{s})^2} = \boxed{0.644}$$

86 •• A 0.25-kg tether ball is attached to a vertical pole by a 1.2-m cord. Assume the radius of the ball is negligible. If the ball moves in a horizontal circle with the cord making an angle of 20º with the vertical, (*a*) what is the tension in the cord? (*b*) What is the speed of the ball?

Picture the Problem The forces acting on the tetherball are shown superimposed on a pictorial representation of the motion. The horizontal component of $\vec{T}$ is the centripetal force. Applying Newton's second law of motion and solving the resulting equations will yield both the tension in the cord and the speed of the ball.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the tetherball:

$$\sum F_x = T\sin 20° = m\frac{v^2}{r}$$

and

$$\sum F_y = T\cos 20° - mg = 0$$

Solve the y equation for T:

$$T = \frac{mg}{\cos 20°}$$

Substitute numerical values and evaluate T:

$$T = \frac{(0.25\,\text{kg})(9.81\,\text{m/s}^2)}{\cos 20°} = \boxed{2.6\,\text{N}}$$

(*b*) Eliminate T between the force equations and solve for v to obtain:

$$v = \sqrt{rg\tan 20°}$$

Note from the diagram that:

$$r = L\sin 20°$$

Substitute for r in the expression for v to obtain:

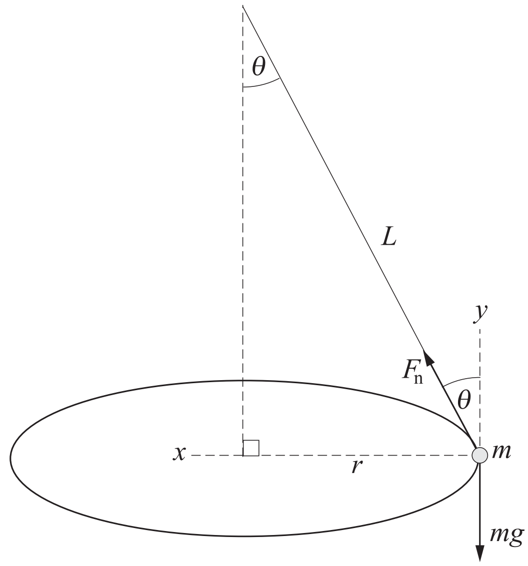
$$v = \sqrt{gL\sin 20°\tan 20°}$$

Substitute numerical values and evaluate v:

$$v=\sqrt{(9.81\,\text{m/s}^2)(1.2\,\text{m})\sin 20^\circ \tan 20^\circ}=\boxed{1.2\,\text{m/s}}$$

87 ••• A small bead with a mass of 100 g (Figure 5-75) slides without friction along a semicircular wire with a radius of 10 cm that rotates about a vertical axis at a rate of 2.0 revolutions per second. Find the value of θ for which the bead will remain stationary relative to the rotating wire.

Picture the Problem The semicircular wire of radius 10 cm limits the motion of the bead in the same manner as would a 10-cm string attached to the bead and fixed at the center of the semicircle. The horizontal component of the normal force the wire exerts on the bead is the centripetal force. The application of Newton's second law, the definition of the speed of the bead in its orbit, and the relationship of the frequency of a circular motion to its period will yield the angle at which the bead will remain stationary relative to the rotating wire.



Apply $\sum \vec{F} = m\vec{a}$ to the bead:

$$\sum F_x = F_n \sin\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - mg = 0$$

Eliminate F_n from the force equations to obtain:

$$\tan\theta = \frac{v^2}{rg}$$

The frequency of the motion is the reciprocal of its period T. Express the speed of the bead as a function of the radius of its path and its period:

$$v=\frac{2\pi r}{T}$$

Using the diagram, relate r to L and θ:

$$r = L\sin\theta$$

Substitute for r and v in the expression for $\tan\theta$ and solve for θ:

$$\theta = \cos^{-1}\left[\frac{gT^2}{4\pi^2 L}\right]$$

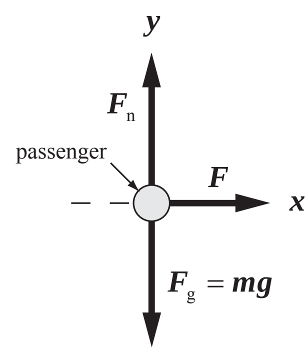
Substitute numerical values and evaluate θ:

$$\theta = \cos^{-1}\left[\frac{\left(9.81\,\text{m/s}^2\right)\left(0.50\,\text{s}\right)^2}{4\pi^2\left(0.10\,\text{m}\right)}\right] = \boxed{52°}$$

Centripetal Force

88 • A car speeds along the curved exit ramp of a freeway. The radius of the curve is 80.0 m. A 70.0-kg passenger holds the armrest of the car door with a 220-N force in order to keep from sliding across the front seat of the car. (Assume the exit ramp is not banked and ignore friction with the car seat.) What is the car's speed?

Picture the Problem The force $\vec{F}$ the passenger exerts on the armrest of the car door is the radial force required to maintain the passenger's speed around the curve and is related to that speed through Newton's second law of motion.



Apply $\sum F_x = ma_x$ to the forces acting on the passenger:

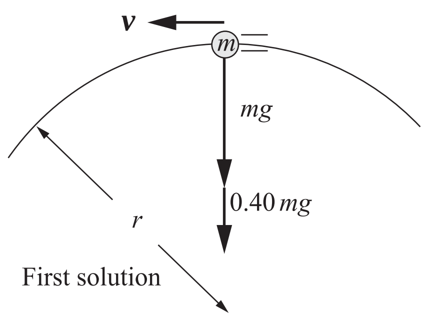
$$F = m\frac{v^2}{r} \Rightarrow v = \sqrt{\frac{rF}{m}}$$

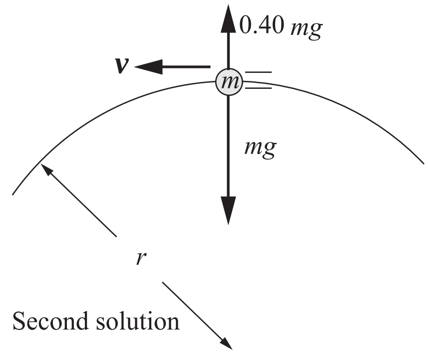
Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{\left(80.0\,\text{m}\right)\left(220\,\text{N}\right)}{70.0\,\text{kg}}} = \boxed{15.9\,\text{m/s}}$$

89 • **[SSM]** The radius of curvature of the track at the top of a loop-the-loop on a roller-coaster ride is 12.0 m. At the top of the loop, the force that the seat exerts on a passenger of mass m is $0.40mg$. How fast is the roller-coaster car moving as it moves through the highest point of the loop.

Picture the Problem There are two solutions to this problem. Pictorial diagrams that include a free-body diagram for each solution are shown below. The speed of the roller coaster is embedded in the expression for its radial acceleration and the radial acceleration is determined by the net radial force force exerted on the passenger by the seat of the roller coaster. We can use Newton's second law to relate the net force on the passenger to the speed of the roller coaster.





First solution

Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the passenger:

$$mg + 0.40mg = m\frac{v^2}{r} \Rightarrow v = \sqrt{1.40gr}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(1.40)(9.81\,\text{m/s}^2)(12.0\,\text{m})} = \boxed{12.8\,\text{m/s}}$$

Second solution

Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the passenger:

$$mg - 0.40mg = m\frac{v^2}{r} \Rightarrow v = \sqrt{0.60gr}$$

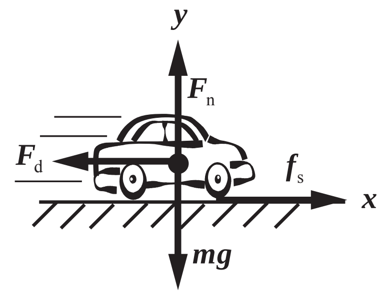
Substitute numerical values and evaluate v:

$$v = \sqrt{(0.60)(9.81\,\text{m/s}^2)(12.0\,\text{m})} = \boxed{8.4\,\text{m/s}}$$

90 •• On a runway of a decommissioned airport, a 2000-kg car travels at a constant speed of 100 km/h. At 100-km/h the air drag on the car is 500 N. Assume that rolling friction is negligible. (*a*) What is the force of static friction exerted on the car by the runway surface, and what is the minimum coefficient of static friction necessary for the car to sustain this speed? (*b*) The car continues to travel at 100 km/h, but now along a path with radius of curvature *r*. For what value of *r* will the angle between the static frictional force vector and the velocity vector equal 45.0°, and for what value of *r* will it equal 88.0°? (*c*) What is the minimum coefficient of static friction necessary for the car to hold this last radius of curvature without skidding?

Picture the Problem (*a*) We can apply Newton's second law to the car to find the force of static friction exerted on the car by the surface and use the definition of the coefficient of static friction to find the minimum coefficient of static friction necessary for the car to sustain its speed. In Part (*b*), we can again apply Newton's second law, this time in both tangential and radial form, to find the values of *r* for the given angles.

(*a*) The forces acting on the car as it moves at a constant speed of 100 km/h are shown in the pictorial representation to the right.



Apply $\sum\vec{F} = m\vec{a}$ to the car to obtain:

$$\sum F_x = f_s - F_d = 0 \qquad (1)$$

and

$$\sum F_y = F_n - mg = 0 \qquad (2)$$

Solving equation (1) for f_s yields:

$$f_s = F_d = \boxed{500\text{ N}}$$

Use the definition of the coefficient of static friction to obtain:

$$\mu_{s,\,min} = \frac{f_s}{F_n}$$

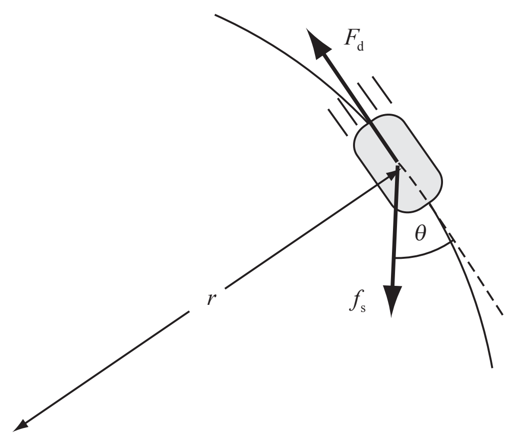
From equation (2), $F_n = mg$; hence:

$$\mu_{s,\,min} = \frac{f_s}{mg}$$

Substitute numerical values and evaluate $\mu_{s,\,min}$:

$$\mu_{s,\,min} = \frac{500\text{ N}}{(2000\text{ kg})(9.81\text{ m/s}^2)} = \boxed{0.0255}$$

(*b*) The horizontal forces acting on the car (shown as a top view) as it travels clockwise along a path of radius of curvature *r* are shown in the diagram to the right.



Apply $\sum F_{radial} = ma_c$ to the car to obtain:

$$f_s \sin\theta = m\frac{v^2}{r} \qquad (1)$$

Appling $\sum F_{\text{tangential}} = ma_{\text{t}}$ to the car yields:

$$f_{\text{s}}\cos\theta - F_{\text{d}} = 0$$

or

$$f_{\text{s}}\cos\theta = F_{\text{d}} \qquad (2)$$

Divide equation (1) by equation (2):

$$\tan\theta = \frac{mv^2}{rF_{\text{d}}} \Rightarrow r = \frac{mv^2}{F_{\text{d}}\tan\theta}$$

Substitute numerical values and evaluate r for $\theta = 45.0°$:

$$r = \frac{(2000\ \text{kg})\left(100\frac{\text{km}}{\text{h}}\cdot\frac{10^3\ \text{m}}{\text{km}}\cdot\frac{1\ \text{h}}{3600\ \text{s}}\right)^2}{(500\ \text{N})\tan 45.0°} = \boxed{3.09\ \text{km}}$$

Substitute numerical values and valuate r for $\theta = 88.0°$:

$$r = \frac{(2000\ \text{kg})\left(100\frac{\text{km}}{\text{h}}\cdot\frac{10^3\ \text{m}}{\text{km}}\cdot\frac{1\ \text{h}}{3600\ \text{s}}\right)^2}{(500\ \text{N})\tan 88.0°} = 107.8\ \text{m} = \boxed{108\ \text{m}}$$

(*c*) The minimum coefficient of static friction necessary for the car to hold this last radius of curvature without skidding is given by:

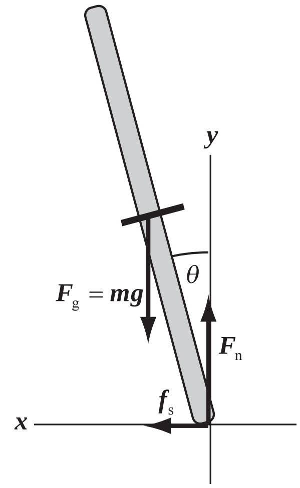
$$\mu_{\text{s, min}} = \frac{f_{\text{s, min}}}{mg} = \frac{m\frac{v^2}{r}}{mg} = \frac{v^2}{rg}$$

Substitute numerical values and evaluate $\mu_{\text{s, min}}$:

$$\mu_{\text{s, min}} = \frac{\left(100\frac{\text{km}}{\text{h}}\cdot\frac{10^3\ \text{m}}{\text{km}}\cdot\frac{1\ \text{h}}{3600\ \text{s}}\right)^2}{(107.8\ \text{m})(9.81\ \text{m/s}^2)} = \boxed{0.730}$$

91 •• Suppose you ride a bicycle in a 20-m-radius circle on a horizontal surface. The resultant force exerted by the surface on the bicycle (normal force plus frictional force) makes an angle of 15º with the vertical. (*a*) What is your speed? (*b*) If the frictional force on the bicycle is half its maximum possible value, what is the coefficient of static friction?

Picture the Problem The forces acting on the bicycle are shown in the force diagram. The static friction force is the centripetal force exerted by the surface on the bicycle that allows it to move in a circular path. $\vec{F}_n + \vec{f}_s$ makes an angle θ with the vertical direction. The application of Newton's second law will allow us to relate this angle to the speed of the bicycle and the coefficient of static friction.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the bicycle:

$$\sum F_x = f_s = \frac{mv^2}{r}$$

and

$$\sum F_y = F_n - mg = 0$$

Relate F_n and f_s to θ:

$$\tan\theta = \frac{f_s}{F_n} = \frac{\frac{mv^2}{r}}{mg} = \frac{v^2}{rg}$$

Solving for v yields:

$$v = \sqrt{rg\tan\theta}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(20\,\text{m})(9.81\,\text{m/s}^2)\tan 15°}$$
$$= \boxed{7.3\,\text{m/s}}$$

(*b*) Relate f_s to μ_s and F_n:

$$f_s = \tfrac{1}{2} f_{s,\max} = \tfrac{1}{2}\mu_s mg$$

Solve for μ_s and substitute for f_s to obtain:

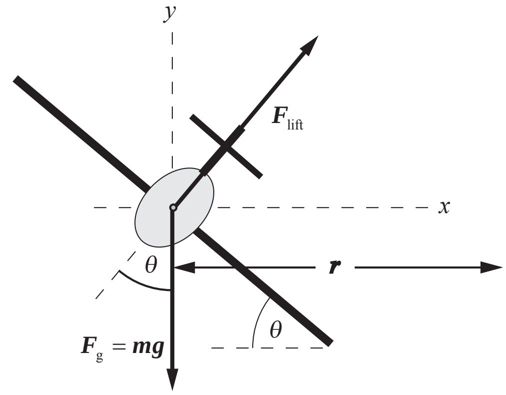
$$\mu_s = \frac{2f_s}{mg} = \frac{2v^2}{rg}$$

Substitute numerical values and evaluate μ_s

$$\mu_s = \frac{2(7.25\,\text{m/s})^2}{(20\,\text{m})(9.81\,\text{m/s}^2)} = \boxed{0.54}$$

92 •• An airplane is flying in a horizontal circle at a speed of 480 km/h. The plane is banked for this turn, its wings tilted at an angle of 40º from the horizontal (Figure 5-76). Assume that a lift force acting perpendicular to the wings acts on the aircraft as it moves through the air. What is the radius of the circle in which the plane is flying?

Picture the Problem The diagram shows the forces acting on the plane as it flies in a horizontal circle of radius r. We can apply Newton's second law to the plane and eliminate the lift force in order to obtain an expression for r as a function of v and θ.



Apply $\sum \vec{F} = m\vec{a}$ to the plane:

$$\sum F_x = F_{\text{lift}} \sin\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F_{\text{lift}} \cos\theta - mg = 0$$

Eliminate F_{lift} between these equations to obtain:

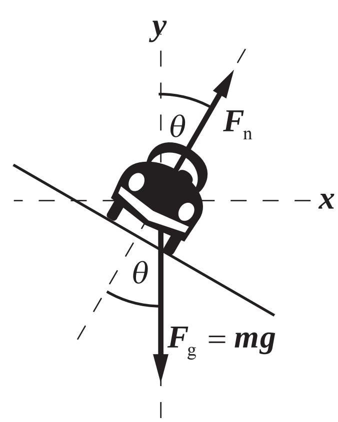
$$\tan\theta = \frac{v^2}{rg} \Rightarrow r = \frac{v^2}{g\tan\theta}$$

Substitute numerical values and evaluate r:

$$r = \frac{\left(480\frac{\text{km}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{\left(9.81\,\text{m/s}^2\right)\tan 40°} = \boxed{2.2\,\text{km}}$$

93 •• An automobile club plans to race a 750-kg car at the local racetrack. The car needs to be able to travel around several 160-m-radius curves at 90 km/h. What should the banking angle of the curves be so that the force of the pavement on the tires of the car is in the normal direction? (*Hint: What does this requirement tell you about the frictional force?*)

Picture the Problem Under the conditions described in the problem statement, the only forces acting on the car are the normal force exerted by the road and the gravitational force exerted by Earth. The horizontal component of the normal force is the centripetal force. The application of Newton's second law will allow us to express θ in terms of v, r, and g.



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = F_n \sin\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - mg = 0$$

Eliminate F_n from the force equations to obtain:

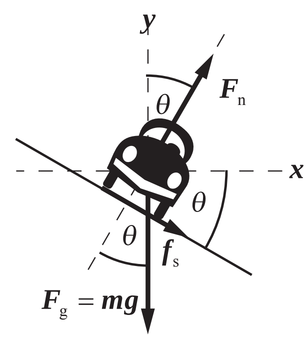
$$\tan\theta = \frac{v^2}{rg} \Rightarrow \theta = \tan^{-1}\left[\frac{v^2}{rg}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left\{\frac{\left(90\,\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{(160\,\text{m})(9.81\,\text{m/s}^2)}\right\} = \boxed{22°}$$

94 •• A curve of radius 150 m is banked at an angle of 10º. An 800-kg car negotiates the curve at 85 km/h without skidding. Neglect the effects of air drag and rolling friction. Find (*a*) the normal force exerted by the pavement on the tires, (*b*) the frictional force exerted by the pavement on the tires, (*c*) the minimum coefficient of static friction between the pavement and the tires.

Picture the Problem Both the normal force and the static friction force contribute to the centripetal force in the situation described in this problem. We can apply Newton's second law to relate f_s and F_n and then solve these equations simultaneously to determine each of these quantities.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = F_n \sin\theta + f_s \cos\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - f_s \sin\theta - mg = 0$$

Multiply the x equation by $\sin\theta$ and the y equation by $\cos\theta$ to obtain:

$$f_s \sin\theta\cos\theta + F_n \sin^2\theta = m\frac{v^2}{r}\sin\theta$$

and

$$F_n \cos^2\theta - f_s \sin\theta\cos\theta - mg\cos\theta = 0$$

Add these equations to eliminate f_s:

$$F_n - mg\cos\theta = m\frac{v^2}{r}\sin\theta$$

Solve for F_n:

$$F_n = mg\cos\theta + m\frac{v^2}{r}\sin\theta$$
$$= m\left(g\cos\theta + \frac{v^2}{r}\sin\theta\right)$$

Substitute numerical values and evaluate F_n:

$$F_n = (800\,\text{kg})\left[(9.81\,\text{m/s}^2)\cos 10° + \frac{\left(85\,\frac{\text{km}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{150\,\text{m}}\sin 10°\right] = 8.245\,\text{kN}$$
$$= \boxed{8.3\,\text{kN}}$$

(*b*) Solve the *y*-equation for f_s:

$$f_s = \frac{F_n\cos\theta - mg}{\sin\theta}$$

Substitute numerical values and evaluate f_s:

$$f_s = \frac{(8.245\,\text{kN})\cos 10° - (800\,\text{kg})(9.81\,\text{m/s}^2)}{\sin 10°} = 1.565\,\text{kN} = \boxed{1.6\,\text{kN}}$$

(*c*) Express $\mu_{s,\min}$ in terms of f_s and F_n:

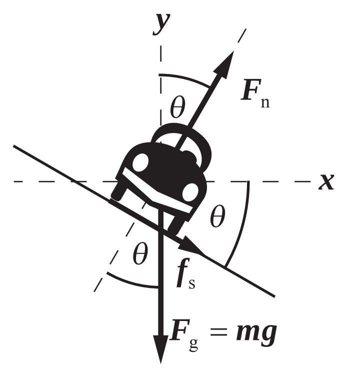
$$\mu_{s,\min} = \frac{f_s}{F_n}$$

Substitute numerical values and evaluate $\mu_{s,\min}$:

$$\mu_{s,\min} = \frac{1.565\,\text{kN}}{8.245\,\text{kN}} = \boxed{0.19}$$

95 •• On another occasion, the car in Problem 94 negotiates the curve at 38 km/h. Neglect the effects of air drag and rolling friction. Find (*a*) the normal force exerted on the tires by the pavement, and (*b*) the frictional force exerted on the tires by the pavement.

Picture the Problem Both the normal force and the static friction force contribute to the centripetal force in the situation described in this problem. We can apply Newton's second law to relate f_s and F_n and then solve these equations simultaneously to determine each of these quantities.



(a) Apply $\sum\vec{F} = m\vec{a}$ to the car:

$$\sum F_x = F_n \sin\theta + f_s \cos\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - f_s \sin\theta - mg = 0$$

Multiply the x equation by $\sin\theta$ and the y equation by $\cos\theta$:

$$f_s \sin\theta\cos\theta + F_n \sin^2\theta = m\frac{v^2}{r}\sin\theta$$

$$F_n \cos^2\theta - f_s \sin\theta\cos\theta - mg\cos\theta = 0$$

Add these equations to eliminate f_s:

$$F_n - mg\cos\theta = m\frac{v^2}{r}\sin\theta$$

Solving for F_n yields:

$$F_n = mg\cos\theta + m\frac{v^2}{r}\sin\theta = m\left(g\cos\theta + \frac{v^2}{r}\sin\theta\right)$$

Substitute numerical values and evaluate F_n:

$$F_n = (800\,\text{kg})\left[(9.81\,\text{m/s}^2)\cos 10^\circ + \frac{\left(38\,\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{150\,\text{m}}\sin 10^\circ\right] = 7.83\,\text{kN}$$

$$= \boxed{7.8\,\text{kN}}$$

(b) Solve the y equation for f_s:

$$f_s = \frac{F_n\cos\theta - mg}{\sin\theta} = F_n\cot\theta - \frac{mg}{\sin\theta}$$

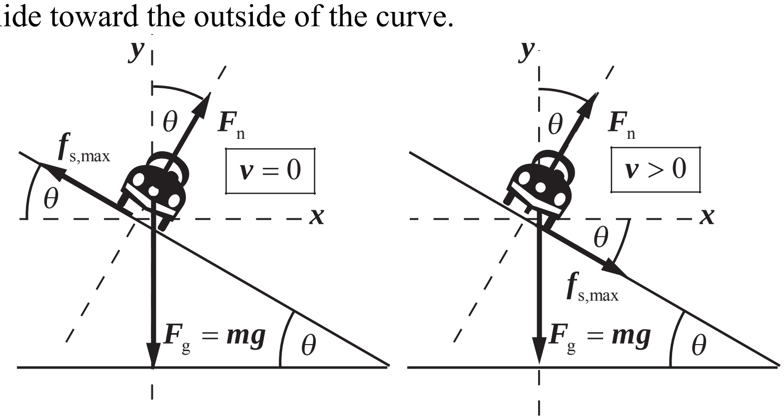
Substitute numerical values and evaluate f_s:

$$f_s = (7.83\ \text{kN})\cot 10° - \frac{(800\ \text{kg})(9.81\ \text{m/s}^2)}{\sin 10°} = \boxed{-0.78\ \text{kN}}$$

The negative sign tells us that f_s points upward along the inclined plane rather than as shown in the force diagram.

96 ••• As a civil engineer intern during one of your summers in college, you are asked to design a curved section of roadway that meets the following conditions: When ice is on the road, and the coefficient of static friction between the road and rubber is 0.080, a car at rest must not slide into the ditch and a car traveling less than 60 km/h must not skid to the outside of the curve. Neglect the effects of air drag and rolling friction. What is the minimum radius of curvature of the curve and at what angle should the road be banked?

Picture the Problem The free-body diagram to the left is for the car at rest. The static friction force up the incline balances the downward component of the car's weight and prevents it from sliding. In the free-body diagram to the right, the static friction force points in the opposite direction as the tendency of the moving car is to slide toward the outside of the curve.



Apply $\sum \vec{F} = m\vec{a}$ to the car that is at rest:

$$\sum F_y = F_n \cos\theta + f_s \sin\theta - mg = 0 \quad (1)$$

and

$$\sum F_x = F_n \sin\theta - f_s \cos\theta = 0 \quad (2)$$

Substitute $f_s = f_{s,max} = \mu_s F_n$ in equation (2) and solve for the maximum allowable value of θ:

$$\theta = \tan^{-1}(\mu_s)$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}(0.080) = 4.57° = \boxed{4.6°}$$

Apply $\sum \vec{F} = m\vec{a}$ to the car that is moving with speed v:

$$\sum F_y = F_n \cos\theta - f_s \sin\theta - mg = 0 \quad (3)$$

$$\sum F_x = F_n \sin\theta + f_s \cos\theta = m\frac{v^2}{r} \quad (4)$$

Substitute $f_s = \mu_s F_n$ in equations (3) and (4) and simplify to obtain:

$$F_n\left(\cos\theta - \mu_s \sin\theta\right) = mg \quad (5)$$

and

$$F_n\left(\mu_s \cos\theta + \sin\theta\right) = m\frac{v^2}{r} \quad (6)$$

Substitute numerical values in equations (5) and (6) to obtain:

$$0.9904F_n = mg$$

and

$$0.1595F_n = m\frac{v^2}{r}$$

Eliminate F_n between these equations and solve for r:

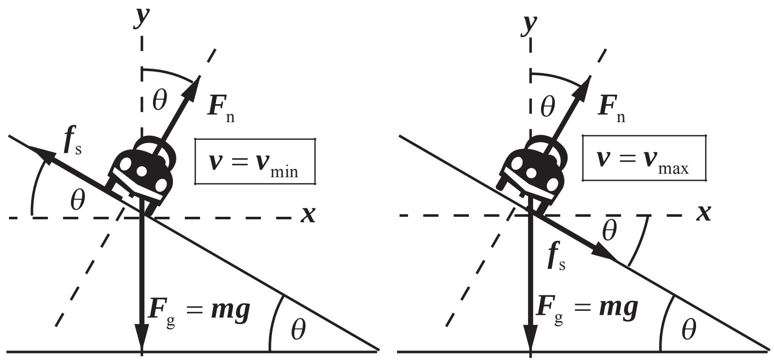
$$r = \frac{v^2}{0.1610g}$$

Substitute numerical values and evaluate r:

$$r = \frac{\left(60\,\frac{\text{km}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{0.1610\left(9.81\,\text{m/s}^2\right)} = \boxed{0.18\,\text{km}}$$

97 ••• A curve of radius 30 m is banked so that a 950-kg car traveling at 40.0 km/h can round it even if the road is so icy that the coefficient of static friction is approximately zero. You are commissioned to tell the local police the range of speeds at which a car can travel around this curve without skidding. Neglect the effects of air drag and rolling friction. If the coefficient of static friction between the road and the tires is 0.300, what is the range of speeds you tell them?

Picture the Problem The free-body diagram to the left is for the car rounding the curve at the minimum (not sliding down the incline) speed. The combination of the horizontal components of the frictional force and the normal force provides the net force toward the center of the curve. In the free-body diagram to the right, the static friction force points in the opposite direction as the tendency of the car moving with the maximum safe speed is to slide toward the outside of the curve. Application of Newton's second law and the simultaneous solution of the force equations will yield v_{min} and v_{max}.



Apply $\sum \vec{F} = m\vec{a}$ to a car traveling around the curve when the coefficient of static friction is zero:

$$\sum F_x = F_n \sin\theta = m\frac{v_{min}^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - mg = 0$$

Divide the first of these equations by the second to obtain:

$$\tan\theta = \frac{v^2}{rg} \Rightarrow \theta = \tan^{-1}\left(\frac{v^2}{rg}\right)$$

Substitute numerical values and evaluate the banking angle:

$$\theta = \tan^{-1}\left[\frac{\left(40\frac{\text{km}}{\text{h}}\times\frac{10^3\,\text{m}}{\text{km}}\times\frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{(30\,\text{m})(9.81\,\text{m/s}^2)}\right] = 22.76°$$

Apply $\sum \vec{F} = m\vec{a}$ to the car traveling around the curve at minimum speed:

$$\sum F_x = F_n \sin\theta - f_s \cos\theta = m\frac{v_{min}^2}{r}$$

and

$$\sum F_y = F_n \cos\theta + f_s \sin\theta - mg = 0$$

Substitute $f_s = f_{s,max} = \mu_s F_n$ in the force equations and simplify to obtain:

$$F_n(\sin\theta - \mu_s \cos\theta) = m\frac{v_{min}^2}{r}$$

and

$$F_n(\cos\theta + \mu_s \sin\theta) = mg$$

Evaluate these equations for θ = 22.876 and μ_s = 0.300:

$$0.1102F_n = m\frac{v_{min}^2}{r} \text{ and } 1.038F_n = mg$$

Eliminate F_n between these two equations and solve for v_{min}:

$$v_{min} = \sqrt{0.106rg}$$

Substitute numerical values and evaluate v_{min}:

$$v_{min} = \sqrt{0.106(30\,\text{m})(9.81\,\text{m/s}^2)} = 5.6\,\text{m/s} \approx 20\,\text{km/h}$$

Apply $\sum \vec{F} = m\vec{a}$ to the car traveling around the curve at maximum speed:

$$\sum F_x = F_n \sin\theta + f_s \cos\theta = m\frac{v_{max}^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - f_s \sin\theta - mg = 0$$

Substitute $f_s = f_{s,\,max} = \mu_s F_n$ in the force equations and simplify to obtain:

$$F_n(\mu_s \cos\theta + \sin\theta) = m\frac{v_{max}^2}{r}$$

and

$$F_n(\cos\theta - \mu_s \sin\theta) = mg$$

Evaluate these equations for $\theta = 22.76°$ and $\mu_s = 0.300$:

$$0.6635F_n = m\frac{v_{max}^2}{r}$$

and

$$0.8061F_n = 0.8061mg$$

Eliminate F_n between these two equations and solve for v_{max}:

$$v_{max} = \sqrt{0.8231rg}$$

Substitute numerical values and evaluate v_{max}:

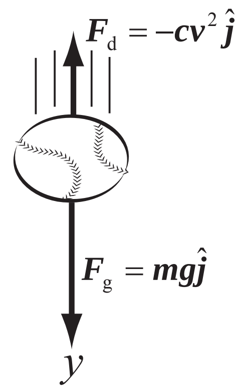
$$v_{max} = \sqrt{(0.8231)(30\,\text{m})(9.81\,\text{m/s}^2)} = 16\,\text{m/s} \approx 56\,\text{km/h}$$

You should tell them that the safe range of speeds is $\boxed{20\,\text{km/m} \le v \le 56\,\text{km/h}}$.

Euler's Method

98 •• You are riding in a hot air balloon when you throw a baseball straight down with an initial speed of 35.0 km/h. The baseball falls with a terminal speed of 150 km/h. Assuming air drag is proportional to the speed squared, use Euler's method (**spreadsheet**) to estimate the speed of the ball after 10.0 s. What is the uncertainty in this estimate? You drop a second baseball, this one released from rest. How long does it take for it to reach 99 percent of its terminal speed? How far does it fall during this time?

Picture the Problem The free-body diagram shows the forces acting on the baseball sometime after it has been thrown downward but before it has reached its terminal speed. In order to use Euler's method, we'll need to determine how the acceleration of the ball varies with its speed. We can do this by applying Newton's second law to the ball and using its terminal speed to express the constant in the acceleration equation in terms of the ball's terminal speed. We can then use $v_{n+1} = v_n + a_n\Delta t$ to find the speed of the ball at any given time.



Apply Newton's second law to the ball to obtain:

$$mg - bv^2 = m\frac{dv}{dt} \Rightarrow \frac{dv}{dt} = g - \frac{b}{m}v^2 \quad (1)$$

When the ball reaches its terminal speed, its acceleration is zero:

$$0 = g - \frac{b}{m}v_{\rm t}^2 \Rightarrow \frac{b}{m} = \frac{g}{v_{\rm t}^2}$$

Substitute in equation (1) to obtain:

$$\frac{dv}{dt} = g\left(1 - \frac{v^2}{v_{\rm t}^2}\right)$$

Express the position of the ball to obtain:

$$x_{n+1} = x_n + \frac{v_{n+1} + v_n}{2}\Delta t$$

Letting a_n be the acceleration of the ball at time t_n, express its speed when $t = t_{n+1}$:

$$v_{n+1} = v_n + a_n\Delta t$$

where $a_n = g\left(1 - \dfrac{v_n^2}{v_{\rm t}^2}\right)$ and Δt is an arbitrarily small interval of time.

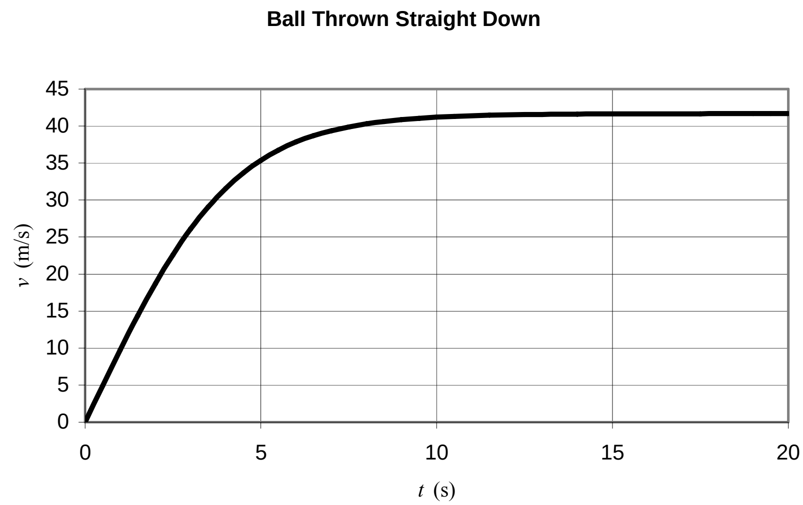
A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
A10	B9+$B$1	$t + \Delta t$
B10	B9+0.5*(C9+C10)*$B$1	$x_{n+1} = x_n + \frac{v_{n+1} + v_n}{2}\Delta t$
C10	C9+D9*$B$1	$v_{n+1} = v_n + a_n\Delta t$
D10	$B$4*(1−C10^2/$B$5^2)	$a_n = g\left(1 - \frac{v_n^2}{v_{\rm t}^2}\right)$

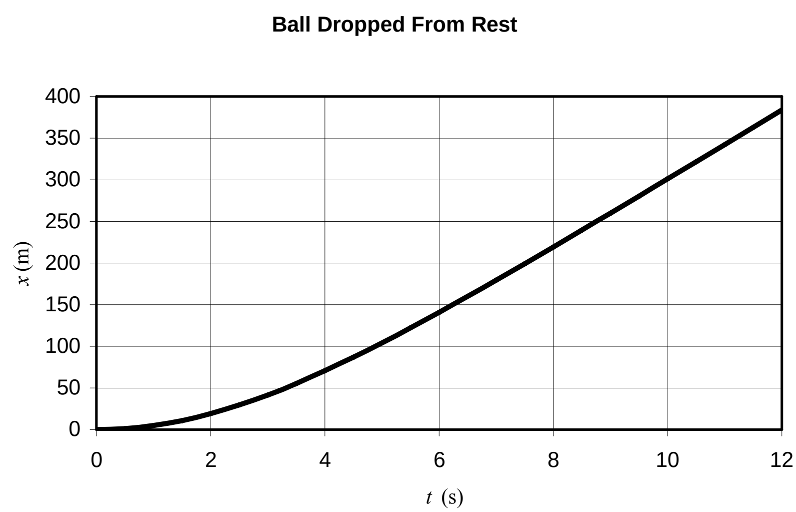
	A	B	C	D
1	Δt=	0.5	s	
2	x_0=	0	m	
3	v_0=	9.722	m/s	
4	a_0=	9.81	m/s^2	
5	v_t=	41.67	m/s	
6				
7	t	x	v	a
8	(s)	(m)	(m/s)	(m/s^2)
9	0.0	0	9.7	9.28
10	0.5	6	14.4	8.64
11	1.0	14	18.7	7.84
12	1.5	25	22.6	6.92
28	9.5	317	41.3	0.17
29	10.0	337	41.4	0.13
30	10.5	358	41.5	0.10
38	14.5	524	41.6	0.01
39	15.0	545	41.7	0.01
40	15.5	566	41.7	0.01
41	16.0	587	41.7	0.01
42	16.5	608	41.7	0.00

From the table we can see that the speed of the ball after 10 s is approximately $\boxed{41.4\,\text{m/s.}}$ We can estimate the uncertainty in this result by halving Δt and recalculating the speed of the ball at t = 10 s. Doing so yields v(10 s) ≈ 41.3 m/s, a difference of about $\boxed{0.02\%.}$

The following graph shows the velocity of the ball thrown straight down as a function of time.

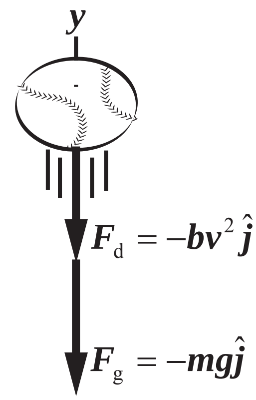


Reset Δt to 0.5 s and set $v_0 = 0$. Ninety-nine percent of 41.67 m/s is approximately 41.3 m/s. Note that the ball will reach this speed in about $\boxed{10.5\,\text{s}}$ and that the distance it travels in this time is about $\boxed{322\,\text{m.}}$ The following graph shows the distance traveled by the ball dropped from rest as a function of time.



99 •• [SSM] You throw a baseball straight up with an initial speed of 150 km/h. The ball's terminal speed when falling is also 150 km/h. (*a*) Use Euler's method (**spreadsheet**) to estimate its height 3.50 s after release. (*b*) What is the maximum height it reaches? (*c*) How long after release does it reach its maximum height? (*d*) How much later does it return to the ground? (*e*) Is the time the ball spends on the way up less than, the same as, or greater than the time it spends on the way down?

Picture the Problem The free-body diagram shows the forces acting on the baseball after it has left your hand. In order to use Euler's method, we'll need to determine how the acceleration of the ball varies with its speed. We can do this by applying Newton's second law to the baseball. We can then use $v_{n+1} = v_n + a_n\Delta t$ and $x_{n+1} = x_n + v_n\Delta t$ to find the speed and position of the ball.



Apply $\sum F_y = ma_y$ to the baseball:

$$-bv|v| - mg = m\frac{dv}{dt}$$

where $|v| = v$ for the upward part of the flight of the ball and $|v| = -v$ for the downward part of the flight.

Solve for dv/dt to obtain:

$$\frac{dv}{dt} = -g - \frac{b}{m}v|v|$$

Under terminal speed conditions ($|v| = -v_\mathrm{t}$):

$$0 = -g + \frac{b}{m}v_\mathrm{t}^2 \text{ and } \frac{b}{m} = \frac{g}{v_\mathrm{t}^2}$$

Substituting for b/m yields:

$$\frac{dv}{dt} = -g - \frac{g}{v_\mathrm{t}^2}v|v| = -g\left(1 + \frac{v|v|}{v_\mathrm{t}^2}\right)$$

Letting a_n be the acceleration of the ball at time t_n, express its position and speed when $t = t_n + 1$:

$$y_{n+1} = y_n + \tfrac{1}{2}\left(v_n + v_{n-1}\right)\Delta t$$

and

$$v_{n+1} = v_n + a_n\Delta t$$

where $a_n = -g\left(1 + \dfrac{v_n|v_n|}{v_\mathrm{t}^2}\right)$ and Δt is an arbitrarily small interval of time.

A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
D11	D10+$B$6	$t + \Delta t$
E10	41.7	v_0
E11	E10−$B$4*	$v_{n+1} = v_n + a_n\Delta t$

	(1+E10*ABS(E10)/($B$5^2))*$B$6	
F10	0	y_0
F11	F10+0.5*(E10+E11)*$B$6	$y_{n+1} = y_n + \frac{1}{2}(v_n + v_{n-1})\Delta t$

G11	$E$10*D11–0.5*$B$4*D11^2	$v_0 t - \frac{1}{2} g t^2$

	A	B	C	D	E	F	G
4	$g=$	9.81	m/s^2				
5	$v_t=$	41.7	m/s				
6	$\Delta t=$	0.1	s				
7							
8							
9				t	v	y	$y_{\text{no drag}}$
10				0.00	41.70	0.00	0.00
11				0.10	39.74	4.07	4.12
12				0.20	37.87	7.95	8.14
40				3.00	3.01	60.13	81.00
41				3.10	2.03	60.39	82.18
42				3.20	1.05	60.54	83.26
43				3.30	0.07	60.60	84.25
44				3.40	–0.91	60.55	85.14
45				3.50	–1.89	60.41	85.93
46				3.60	–2.87	60.17	86.62
78				6.80	–28.34	6.26	56.98
79				6.90	–28.86	3.41	54.44
80				7.00	–29.37	0.49	51.80
81				7.10	–29.87	–2.47	49.06

(*a*) When $t = 3.50$ s, the height of the ball is about $\boxed{60.4\,\text{m}}$.

(*b*) The maximum height reached by the ball is $\boxed{60.6\,\text{m}}$.

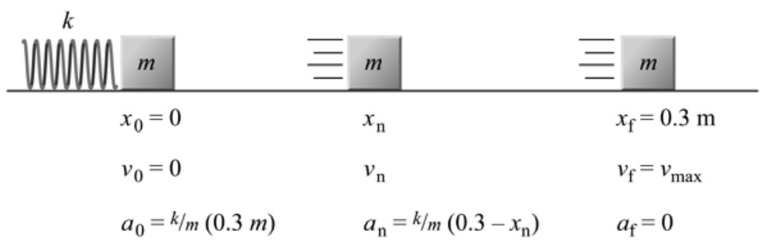
(*c*) The time the ball takes to reach its maximum height is about $\boxed{3.0\,\text{s}}$.

(*d*) The ball hits the ground at about $t = \boxed{7.0\,\text{s}}$

(*e*) Because the time the ball takes to reach its maximum height is less than half its time of flight, the time the ball spends on the way up less than the time it spends on the way down

100 ••• A 0.80-kg block on a horizontal frictionless surface is held against a massless spring, compressing it 30 cm. The force constant of the spring is 50 N/m. The block is released and the spring pushes it 30 cm. Use Euler's method (**spreadsheet**) with $\Delta t = 0.005$ s to estimate the time it takes for the spring to push the block the 30 cm. How fast is the block moving at this time? What is the uncertainty in this speed?

Picture the Problem The pictorial representation shows the block in its initial position against the compressed spring, later as the spring accelerates it to the right, and finally when it has reached its maximum speed at $x_f = 0.30$ m. In order to use Euler's method, we'll need to determine how the acceleration of the block varies with its position. We can do this by applying Newton's second law to the block. We can then use $v_{n+1} = v_n + a_n\Delta t$ and $x_{n+1} = x_n + v_n\Delta t$ to find the speed and position of the block.



Apply $\sum F_x = ma_x$ to the block:

$$k(0.30\,\text{m} - x_n) = ma_n$$

Solve for a_n:

$$a_n = \frac{k}{m}(0.30\,\text{m} - x_n)$$

Express the position and speed of the block when $t = t_n + 1$:

$$x_{n+1} = x_n + v_n\Delta t$$

and

$$v_{n+1} = v_n + a_n\Delta t$$

where $a_n = \dfrac{k}{m}(0.30\,\text{m} - x_n)$ and Δt is an arbitrarily small interval of time.

A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
A10	A9+$B$1	$t + \Delta t$
B10	B9+C10*$B$1	$x_n + v_n\Delta t$
C10	C9+D9*$B$1	$v_n + a_n\Delta t$
D10	($B$4/$B$5)*(0.30–B10)	$\frac{k}{m}(0.30 - x_n)$

	A	B	C	D
1	Δt=	0.005	s	
2	x_0=	0	m	
3	v_0=	0	m/s	
4	k =	50	N/m	
5	m =	0.80	kg	
6				
7	t	x	v	a
8	(s)	(m)	(m/s)	(m/s^2)
9	0.000	0.00	0.00	18.75
10	0.005	0.00	0.09	18.72
11	0.010	0.00	0.19	18.69
12	0.015	0.00	0.28	18.63
45	0.180	0.25	2.41	2.85
46	0.185	0.27	2.42	2.10
47	0.190	0.28	2.43	1.34
48	0.195	0.29	2.44	0.58
49	0.200	0.30	2.44	−0.19

From the table we can see that it took about $\boxed{0.200\,\text{s}}$ for the spring to push the block 30 cm and that it was traveling about $\boxed{2.44\,\text{m/s}}$ at that time. We can estimate the uncertainty in this result by halving Δt and recalculating the speed of the ball at t = 10 s. Doing so yields v(0.20 s) ≈ 2.41 m/s, a difference of about $\boxed{1.2\%.}$

Finding the Center of Mass

101 • Three point masses of 2.0 kg each are located on the x axis. One is at the origin, another at x = 0.20 m, and another at x = 0.50 m. Find the center of mass of the system.

Picture the Problem We can use its definition to find the center of mass of this system.

The x coordinate of the center of mass is given by:

$$x_{\text{cm}} = \frac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{\text{cm}} = \frac{(2.0\,\text{kg})(0) + (2.0\,\text{kg})(0.20\,\text{m}) + (2.0\,\text{kg})(0.50\,\text{m})}{2.0\,\text{kg} + 2.0\,\text{kg} + 2.0\,\text{kg}} = 0.23\,\text{m}$$

Because the point masses all lie along the x axis:

$y_{cm} = 0$ and the center of mass of this system of particles is at $\boxed{(0.23\,\text{m}, 0)}$.

102 • On a weekend archeological dig, you discover an old club-ax that consists of a symmetrical 8.0-kg stone attached to the end of a uniform 2.5-kg stick. You measure the dimensions of the club-ax as shown in Figure 5-77. How far is the center of mass of the club-ax from the handle end of the club-ax?

Picture the Problem Let the left end of the handle be the origin of our coordinate system. We can disassemble the club-ax, find the center of mass of each piece, and then use these coordinates and the masses of the handle and stone to find the center of mass of the club-ax.

Express the center of mass of the handle plus stone system:

$$x_{cm} = \frac{m_{stick}x_{cm,stick} + m_{stone}x_{cm,stone}}{m_{stick} + m_{stone}}$$

Assume that the stone is drilled and the stick passes through it. Use symmetry considerations to locate the center of mass of the stick:

$$x_{cm,stick} = 49\,\text{cm}$$

Use symmetry considerations to locate the center of mass of the stone:

$$x_{cm,stone} = 89\,\text{cm}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{cm} = \frac{(2.5\,\text{kg})(49\,\text{cm}) + (8.0\,\text{kg})(89\,\text{cm})}{2.5\,\text{kg} + 8.0\,\text{kg}} = \boxed{79\,\text{cm}}$$

103 • Three balls A, B, and C, with masses of 3.0 kg, 1.0 kg, and 1.0 kg, respectively, are connected by massless rods, as shown in Figure 5-78. What are the coordinates of the center of mass of this system?

Picture the Problem We can treat each of balls as though they are point objects and apply the definition of the center of mass to find (x_{cm}, y_{cm}).

The x coordinate of the center of mass is given by:

$$x_{cm} = \frac{m_A x_A + m_B x_B + m_C x_C}{m_A + m_B + m_C}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{\text{cm}} = \frac{(3.0\,\text{kg})(2.0\,\text{m}) + (1.0\,\text{kg})(1.0\,\text{m}) + (1.0\,\text{kg})(3.0\,\text{m})}{3.0\,\text{kg} + 1.0\,\text{kg} + 1.0\,\text{kg}} = 2.0\,\text{m}$$

The y coordinate of the center of mass is given by:

$$y_{\text{cm}} = \frac{m_{\text{A}} y_{\text{A}} + m_{\text{B}} y_{\text{B}} + m_{\text{C}} y_{\text{C}}}{m_{\text{A}} + m_{\text{B}} + m_{\text{C}}}$$

Substitute numerical values and evaluate y_{cm}:

$$y_{\text{cm}} = \frac{(3.0\,\text{kg})(2.0\,\text{m}) + (1.0\,\text{kg})(1.0\,\text{m}) + (1.0\,\text{kg})(0)}{3.0\,\text{kg} + 1.0\,\text{kg} + 1.0\,\text{kg}} = 1.4\,\text{m}$$

The center of mass of this system of balls is at $\boxed{(2.0\,\text{m}, 1.4\,\text{m})}$.

Alternate Solution Using Vectors

Picture the Problem We can use the vector expression for the center of mass to find (x_{cm}, y_{cm}).

The vector expression for the center of mass is:

$$M\vec{\boldsymbol{r}}_{\text{cm}} = \sum_i m_i \vec{\boldsymbol{r}}_i \text{ or } \vec{\boldsymbol{r}}_{\text{cm}} = \frac{\sum_i m_i \vec{\boldsymbol{r}}_i}{M} \qquad (1)$$

where

$$\vec{\boldsymbol{r}}_{\text{cm}} = x_{\text{cm}}\hat{\boldsymbol{i}} + y_{\text{cm}}\hat{\boldsymbol{j}} + z_{\text{cm}}\hat{\boldsymbol{k}}$$

The position vectors for the objects located at A, B, and C are:

$$\vec{\boldsymbol{r}}_{\text{A}} = \left(2.0\hat{\boldsymbol{i}} + 2.0\hat{\boldsymbol{j}} + 0\hat{\boldsymbol{k}}\right)\text{m},$$

$$\vec{\boldsymbol{r}}_{\text{B}} = \hat{\boldsymbol{i}} + \hat{\boldsymbol{j}} + 0\hat{\boldsymbol{k}}\,,$$

and

$$\vec{\boldsymbol{r}}_{\text{C}} = \left(3.0\hat{\boldsymbol{i}} + 0\hat{\boldsymbol{j}} + 0\hat{\boldsymbol{k}}\right)\text{m}$$

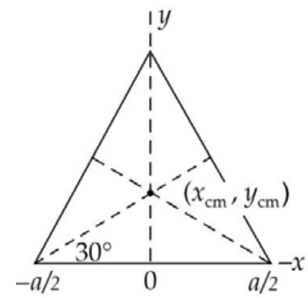
Substitute numerical values in (1) and simplify to obtain:

$$\begin{aligned}\vec{\boldsymbol{r}}_{\text{cm}} &= \frac{1}{(3.0\,\text{kg} + 1.0\,\text{kg} + 1.0\,\text{kg})}\Big[(3.0\,\text{kg})\left(2.0\hat{\boldsymbol{i}} + 2.0\hat{\boldsymbol{j}} + 0\hat{\boldsymbol{k}}\right)\text{m} + (1.0\,\text{kg})\left(\hat{\boldsymbol{i}} + \hat{\boldsymbol{j}} + 0\hat{\boldsymbol{k}}\right)\text{m} \\ &\qquad + (1.0\,\text{kg})\left(3.0\hat{\boldsymbol{i}} + 0\hat{\boldsymbol{j}} + 0\hat{\boldsymbol{k}}\right)\text{m}\Big] \\ &= (2.0\,\text{m})\hat{\boldsymbol{i}} + (1.4\,\text{m})\hat{\boldsymbol{j}} + 0\hat{\boldsymbol{k}}\end{aligned}$$

The center of mass of this system of balls is at $\boxed{(2.0\,\text{m}, 1.4\,\text{m}, 0)}$.

104 • By symmetry, locate the center of mass of an equilateral triangle with edges of length a. The triangle has one vertex on the y axis and the others at $(-a/2, 0)$ and $(+a/2, 0)$.

Picture the Problem The figure shows an equilateral triangle with its y-axis vertex above the x axis. The bisectors of the vertex angles are also shown. We can find x coordinate of the center-of-mass by inspection and the y coordinate using trigonometry.



From symmetry considerations: $x_{cm} = 0$

Express the trigonometric relationship between $a/2$, 30°, and y_{cm}: $\tan 30° = \dfrac{y_{cm}}{\frac{1}{2}a}$

Solve for y_{cm} and simplify to obtain: $y_{cm} = \frac{1}{2}a\tan 30° = 0.29a$

The center of mass of an equilateral triangle oriented as shown above is at $\boxed{(0, 0.29a)}$.

105 •• **[SSM]** Find the center of mass of the uniform sheet of plywood in Figure 5-79. Consider this as a system of effectively two sheets, letting one have a ″negative mass″ to account for the cutout. Thus, one is a square sheet of 3.0-m edge length and mass m_1 and the second is a rectangular sheet measuring 1.0 m × 2.0 m with a mass of $-m_2$. Let the coordinate origin be at the lower left corner of the sheet.

Picture the Problem Let the subscript 1 refer to the 3.0-m by 3.0-m sheet of plywood before the 2.0-m by 1.0-m piece has been cut from it. Let the subscript 2 refer to 2.0-m by 1.0-m piece that has been removed and let σ be the area density of the sheet. We can find the center-of-mass of these two regions; treating the missing region as though it had negative mass, and then finding the center-of-mass of the U-shaped region by applying its definition.

Express the coordinates of the center of mass of the sheet of plywood:

$$x_{\text{cm}} = \frac{m_1 x_{\text{cm},1} - m_2 x_{\text{cm},2}}{m_1 - m_2}$$

and

$$y_{\text{cm}} = \frac{m_1 y_{\text{cm},1} - m_2 y_{\text{cm},2}}{m_1 - m_2}$$

Use symmetry to find $x_{\text{cm},1}$, $y_{\text{cm},1}$, $x_{\text{cm},2}$, and $y_{\text{cm},2}$:

$$x_{\text{cm},1} = 1.5\,\text{m},\ y_{\text{cm},1} = 1.5\,\text{m}$$

and

$$x_{\text{cm},2} = 1.5\,\text{m},\ y_{\text{cm},2} = 2.0\,\text{m}$$

Determine m_1 and m_2:

$$m_1 = \sigma A_1 = 9\sigma\,\text{kg}$$

and

$$m_2 = \sigma A_2 = 2\sigma\,kg$$

Substitute numerical values and evaluate x_{cm}:

$$x_{\text{cm}} = \frac{(9\sigma\,\text{kg})(1.5\,\text{m}) - (2\sigma\,\text{kg})(1.5\,\text{kg})}{9\sigma\,\text{kg} - 2\sigma\,\text{kg}}$$
$$= 1.5\,\text{m}$$

Substitute numerical values and evaluate y_{cm}:

$$\boldsymbol{y}_{\text{cm}} = \frac{(9\boldsymbol{\sigma}\,\text{kg})(1.5\,\text{m}) - (2\boldsymbol{\sigma}\,\text{kg})(2.0\,\text{m})}{9\boldsymbol{\sigma}\,\text{kg} - 2\boldsymbol{\sigma}\,\text{kg}}$$
$$= 1.4\,\text{m}$$

The center of mass of the U-shaped sheet of plywood is at $\boxed{(1.5\,\text{m}, 1.4\,\text{m})}$.

106 •• A can in the shape of a symmetrical cylinder with mass *M* and height *H* is filled with water. The initial mass of the water is *M*, the same mass as the can. A small hole is punched in the bottom of the can, and the water drains out. (*a*) If the height of the water in the can is *x*, what is the height of the center of mass of the can plus the water remaining in the can? (*b*) What is the minimum height of the center of mass as the water drains out?

Picture the Problem We can use its definition to find the center of mass of the can plus water. By setting the derivative of this function equal to zero, we can find the value of *x* that corresponds to the minimum height of the center of mass of the water as it drains out and then use this extreme value to express the minimum height of the center of mass.

(*a*) Using its definition, express the location of the center of mass of the can + water:

$$x_{\text{cm}} = \frac{M\left(\frac{H}{2}\right) + m\left(\frac{x}{2}\right)}{M + m} \qquad (1)$$

Let the cross-sectional area of the can be A and use the definition of density to relate the mass m of water remaining in the can at any given time to its depth x:

$$\rho = \frac{M}{AH} = \frac{m}{Ax} \Rightarrow m = \frac{x}{H}M$$

Substitute for m in equation (1) and simplify to obtain:

$$x_{\text{cm}} = \frac{M\left(\frac{H}{2}\right) + \left(\frac{x}{H}M\right)\left(\frac{x}{2}\right)}{M + \frac{x}{H}M} = \boxed{\frac{H}{2}\left(\frac{1+\left(\frac{x}{H}\right)^2}{1+\frac{x}{H}}\right)}$$

(b) Differentiate x_{cm} with respect to x and set the derivative equal to zero for extrema:

$$\frac{dx_{\text{cm}}}{dx} = \frac{H}{2}\frac{d}{dx}\left(\frac{1+\left(\frac{x}{H}\right)^2}{1+\frac{x}{H}}\right) = \frac{H}{2}\left\{\frac{\left(1+\frac{x}{H}\right)2\left(\frac{x}{H}\right)\left(\frac{1}{H}\right)}{\left(1+\frac{x}{H}\right)^2} - \frac{\left[1+\left(\frac{x}{H}\right)^2\right]\left(\frac{1}{H}\right)}{\left(1+\frac{x}{H}\right)^2}\right\} = 0$$

Simplify this expression to obtain a quadratic equation in x/H:

$$\left(\frac{x}{H}\right)^2 + 2\left(\frac{x}{H}\right) - 1 = 0$$

Solving for x/H yields:

$$x = H\left(\sqrt{2}-1\right) \approx 0.414H$$

where we've kept the positive solution because a negative value for x/H would make no sense.

Use your graphing calculator to convince yourself that the graph of x_{cm} as a function of x is concave upward at $x \approx 0.414H$ and that, therefore, the minimum value of x_{cm} occurs at $x \approx 0.414H$.

Evaluate x_{cm} at $x = H\left(\sqrt{2}-1\right)$ to obtain:

$$x_{\text{cm}}\Big|_{x=H\left(\sqrt{2}-1\right)} = \frac{H}{2}\left(\frac{1+\left(\frac{H\left(\sqrt{2}-1\right)}{H}\right)^2}{1+\frac{H\left(\sqrt{2}-1\right)}{H}}\right)$$

$$= \boxed{H\left(\sqrt{2}-1\right)}$$

107 •• **[SSM]** Two identical thin uniform rods each of length L are glued together so that the angle at the joint is 90°. Determine the location of the center of mass (in terms of L) of this configuration relative to the origin taken to be at the joint. (*Hint: You do not need the mass of the rods (why?), but you should start by assuming a mass m and see that it cancels out.*)

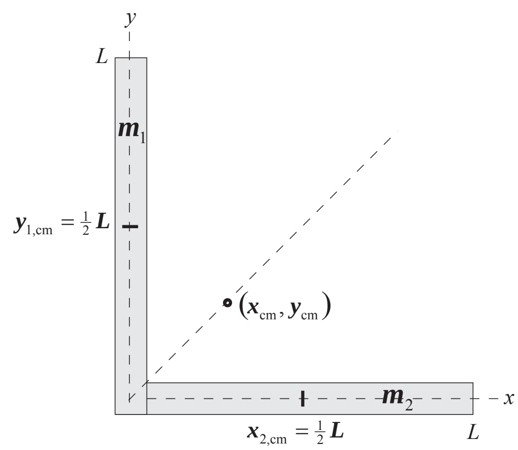
Picture the Problem A pictorial representation of the system is shown to the right. The x and y coordinates of the two rods are

$$(x_{1,\text{cm}}, y_{1,\text{cm}}) = (0, \tfrac{1}{2}L)$$

and

$$(x_{2,\text{cm}}, y_{2,\text{cm}}) = (\tfrac{1}{2}L, 0).$$

We can use the definition of the center of mass to find the coordinates $(x_{\text{cm}}, y_{\text{cm}})$.



The x coordinate of the center of mass is given by:

$$x_{\text{cm}} = \frac{x_{1,\text{cm}} m_1 + x_{2,\text{cm}} m_2}{m_1 + m_2}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{\text{cm}} = \frac{(0)m_1 + (\tfrac{1}{2}L)m_2}{m_1 + m_2}$$

or, because $m_1 = m_2 = m$,

$$x_{\text{cm}} = \frac{(0)m + (\tfrac{1}{2}L)m}{m + m} = \tfrac{1}{4}L$$

The y coordinate of the center of mass is given by:

$$y_{\text{cm}} = \frac{y_{1,\text{cm}} m_1 + y_{2,\text{cm}} m_2}{m_1 + m_2}$$

Substitute numerical values and evaluate y_{cm}:

$$y_{\text{cm}} = \frac{(\tfrac{1}{2}L)m_1 + (0)m_2}{m_1 + m_2}$$

or, because $m_1 = m_2 = m$,

$$y_{\text{cm}} = \frac{(\tfrac{1}{2}L)m + (0)m}{m + m} = \tfrac{1}{4}L$$

The center of mass of this system is located at $\boxed{(\tfrac{1}{4}L, \tfrac{1}{4}L)}$.

Remarks: Note that the center of mass is located at a distance $d = \tfrac{1}{2}L\cos 45°$ from the vertex on the axis of symmetry bisecting the two arms.

108 ••• Repeat the analysis of Problem 107 with a general angle θ at the joint instead of 90°. Does your answer agree with the specific 90°- angle answer in Problem 107 if you set θ equal to 90°? Does your answer give plausible results for angles of zero and 180°?

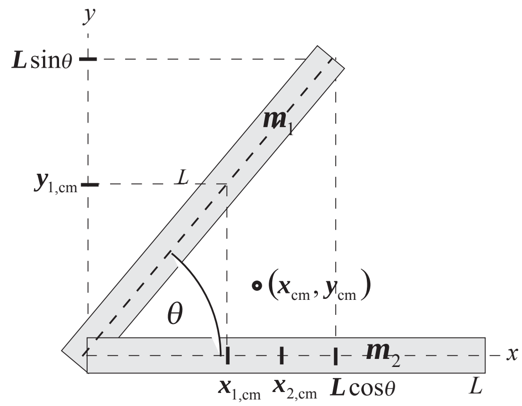
Picture the Problem The pictorial representation of the system is shown to the right. The x and y coordinates of the two rods are

$$(x_{1,\text{cm}}, y_{1,\text{cm}}) = \left(\tfrac{1}{2}L\cos\theta, \tfrac{1}{2}L\sin\theta\right)$$

and

$$(x_{2,\text{cm}}, y_{2,\text{cm}}) = \left(\tfrac{1}{2}L, 0\right).$$

We can use the definition of the center of mass to find the coordinates $(x_{\text{cm}}, y_{\text{cm}})$.



The x coordinate of the center of mass is given by:

$$x_{\text{cm}} = \frac{x_{1,\text{cm}}m_1 + x_{2,\text{cm}}m_2}{m_1 + m_2}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{\text{cm}} = \frac{\left(\tfrac{1}{2}L\cos\theta\right)m_1 + \left(\tfrac{1}{2}L\right)m_2}{m_1 + m_2}$$

or, because $m_1 = m_2 = m$,

$$x_{\text{cm}} = \frac{\left(\tfrac{1}{2}L\cos\theta\right)m + \left(\tfrac{1}{2}L\right)m}{m + m} = \tfrac{1}{4}L(1 + \cos\theta)$$

The y coordinate of the center of mass is given by:

$$y_{\text{cm}} = \frac{y_{1,\text{cm}}m_1 + y_{2,\text{cm}}m_2}{m_1 + m_2}$$

Substitute numerical values and evaluate y_{cm}:

$$y_{\text{cm}} = \frac{\left(\tfrac{1}{2}L\sin\theta\right)m_1 + (0)m_2}{m_1 + m_2}$$

or, because $m_1 = m_2 = m$,

$$y_{\text{cm}} = \frac{\left(\tfrac{1}{2}L\sin\theta\right)m + (0)m}{m + m} = \tfrac{1}{4}L\sin\theta$$

The center of mass of this system of rods is located at $\boxed{\left(\tfrac{1}{4}L(1 + \cos\theta), \tfrac{1}{4}L\sin\theta\right)}$.

For $\theta = 0°$:

$$\left(\tfrac{1}{4}L(1 + \cos\theta), \tfrac{1}{4}L\sin\theta\right) = \left(\tfrac{1}{4}L(1 + \cos 0°), \tfrac{1}{4}L\sin 0°\right) = \boxed{\left(\tfrac{1}{2}L, 0\right)} \text{ as expected.}$$

For $\theta = 90°$:

$$\left(\tfrac{1}{4}L(1+\cos\theta), \tfrac{1}{4}L\sin\theta\right) = \left(\tfrac{1}{4}L(1+\cos 90°), \tfrac{1}{4}L\sin 90°\right)$$
$$= \boxed{\left(\tfrac{1}{4}L, \tfrac{1}{4}L\right)} \text{ in agreement with Problem 107.}$$

For $\theta = 180°$:

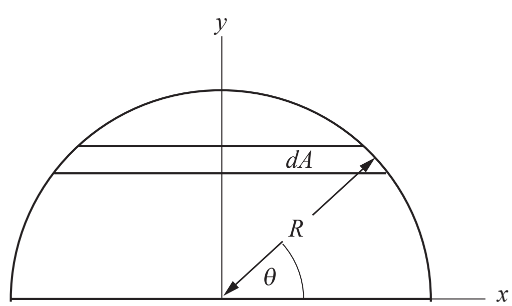
$$\left(\tfrac{1}{4}L(1+\cos\theta), \tfrac{1}{4}L\sin\theta\right) = \left(\tfrac{1}{4}L(1+\cos 180°), \tfrac{1}{4}L\sin 180°\right) = \boxed{(0,0)} \text{ as expected.}$$

Remarks: Note that the center of mass is located at a distance $d = \frac{1}{4}\sqrt{2}L\sqrt{1+\cos\theta}$ from the vertex on an axis that makes an angle $\phi = \tan^{-1}\left[\dfrac{\sin\theta}{1+\cos\theta}\right]$ with the *x* axis.

*Finding the Center of Mass by Integration

109 •• Show that the center of mass of a uniform semicircular disk of radius R is at a point $4R/(3\pi)$ from the center of the circle.

Picture the Problem A semicircular disk and a surface element of area dA is shown in the diagram. Because the disk is a continuous object, we'll use $M\vec{r}_{\text{cm}} = \int \vec{r}\,dm$ and symmetry to find its center of mass.



Express the coordinates of the center of mass of the semicircular disk:

$x_{\text{cm}} = 0$ by symmetry.

$$y_{\text{cm}} = \frac{\int y\sigma\, dA}{M} \qquad (1)$$

Express y as a function of r and θ:

$$y = r\sin\theta$$

Express dA in terms of r and θ:

$$dA = 2r\cos\theta\, dy$$
$$= (2R\cos\theta)(R\cos\theta)d\theta$$
$$= 2R^2\cos^2\theta d\theta$$

Express M as a function of r and θ:

$$M = \sigma A_{\text{half disk}} = \tfrac{1}{2}\sigma\pi R^2 \Rightarrow \sigma = \frac{2M}{\pi R^2}$$

Substitute for y, σ and dA in equation (1) to obtain:

$$y_{\text{cm}} = \frac{2}{\pi R^2}\int_0^{\frac{\pi}{2}} (R\sin\theta)\left(2R^2\cos^2\theta\right)d\theta$$

Simplifying yields:

$$y_{\text{cm}} = \frac{4R}{\pi}\int_0^{\frac{\pi}{2}} \sin\theta\cos^2\theta\, d\theta$$

Change variables by letting $u = \cos\theta$. Then:

$$du = -\sin\theta\, d\theta$$

and

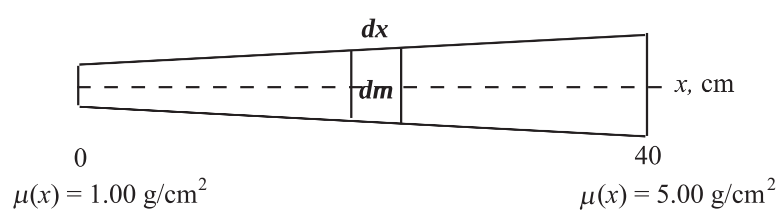
$$y_{\text{cm}} = -\frac{4R}{\pi}\int_{\ell_1}^{\ell_2} u^2\, du = -\frac{4R}{\pi}\left[\frac{u^3}{3}\right]_{\ell_1}^{\ell_2}$$

Substituting for u gives:

$$y_{\text{cm}} = -\frac{4R}{\pi}\left[\frac{\cos^3\theta}{3}\right]_0^{\frac{\pi}{2}} = -\frac{4R}{\pi}\left[-\frac{1}{3}\right] = \boxed{\frac{4R}{3\pi}}$$

110 •• Find the location of the center of mass of a nonuniform rod 0.40 m in length if its density varies linearly from 1.00 g/cm at one end to 5.00 g/cm at the other end. Specify the center-of-mass location relative to the less-massive end of the rod.

Picture the Problem The pictorial representation summarizes the information we're given about the non-uniform rod. We can use the definition of the center of mass for a continuous object to find the center of mass of the non-uniform rod.



The x coordinate of the center of mass of the non-uniform rod is given by:

$$x_{cm} = \frac{\int x dm}{\int dm}$$

or, because $dm = \mu(x)dx$,

$$x_{cm} = \frac{\int x\mu(x)dx}{\int \mu(x)dx} \qquad (1)$$

By symmetry:

$$y_{cm} = 0$$

Use the given information regarding the linear variation in the density of the non-uniform rod to express $\mu(x)$:

$$\mu(x) = 1.00\ \text{g/cm} + (0.10\ \text{g/cm}^2)x$$

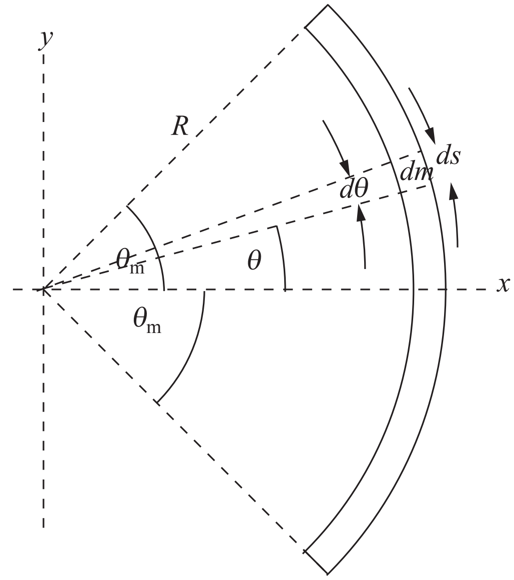
Substituting for $\mu(x)$ in equation (1) and evaluating the integrals yields:

$$x_{cm} = \frac{\int_0^{40\ \text{cm}} x\left[1.00\ \text{g/cm} + (0.10\ \text{g/cm}^2)x\right]xdx}{\int_0^{40\ \text{cm}} \left[1.00\ \text{g/cm} + (0.10\ \text{g/cm}^2)x\right]dx} = 24\ \text{cm}$$

The coordinates of the center of mass of the non-uniform rod are $\boxed{(24\ \text{cm}, 0)}$.

111 ••• You have a thin uniform wire bent into part of a circle that is described by a radius R and angle θ_m (see Figure 5-80). Show that the location of its center of mass is on the x axis and located a distance $x_{cm} = (R \sin \theta_m)/\theta_m$, where θ_m is expressed in radians. Double check by showing that this answer gives the physically expected limit for $\theta_m = 180°$. Verify that your answer gives you the result in the text (in the subsection Finding the Center of Mass by Integration) for the special case of $\theta_m = 90°$.

Picture the Problem We can use the definition of the center of mass for a continuous object to find the center of mass of the non-uniform rod.



The x coordinate of the center of mass of the thin uniform wire is given by:

$$x_{cm} = \frac{\int x dm}{\int dm}$$

or, because $dm = \lambda ds = \lambda R d\theta$,

$$x_{cm} = \frac{\int_{-\theta_m}^{\theta_m} x\lambda R d\theta}{\int_{-\theta_m}^{\theta_m} \lambda R d\theta} = \frac{\int_{-\theta_m}^{\theta_m} x d\theta}{\int_{-\theta_m}^{\theta_m} d\theta} \qquad (1)$$

By symmetry:

$$y_{cm} = 0$$

Because $x = R\cos\theta$, equation (1) becomes:

$$x_{cm} = \frac{\int_{-\theta_m}^{\theta_m} R\cos\theta \, d\theta}{\int_{-\theta_m}^{\theta_m} d\theta} = \frac{R\int_{-\theta_m}^{\theta_m} \cos\theta \, d\theta}{\int_{-\theta_m}^{\theta_m} d\theta}$$

Evaluate these integrals to obtain:

$$x_{cm} = \frac{R\sin\theta_m}{\theta_m}$$

The coordinates of the center of mass of the thin uniform wire are

$$\boxed{\left(\frac{R\sin\theta_m}{\theta_m}, 0\right)}.$$

For $\boldsymbol{\theta}_m = 180° = \boldsymbol{\pi}$ radians:

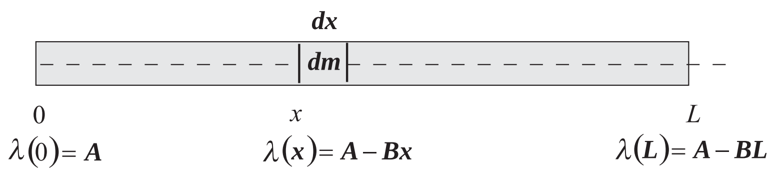
$$x_{cm} = \frac{R\sin\pi}{\pi} = \boxed{0} \text{ as expected.}$$

For $\theta_m = 90° = \frac{\pi}{2}$ radians:

$$x_{cm} = \frac{R\sin\left(\frac{\pi}{2}\right)}{\frac{\pi}{2}} = \boxed{\frac{2R}{\pi}} \text{ as expected.}$$

112 ••• A long, thin wire of length L has a linear mass density given by $A - Bx$, where A and B are positive constants and x is the distance from the more massive end. (*a*) A condition for this problem to be realistic is that $A > BL$. Explain why. (*b*) Determine x_{cm} in terms of L, A, and B. Does your answer makes sense if $B = 0$? Explain.

Picture the Problem The pictorial representation summarizes the information we're given about the long thin wire. We can use the definition of the center of mass for a continuous object to find the center of mass of the non-uniform rod.



(*a*) At the end, the density has to be positive, so $A - BL > 0$ or $A > BL$.

(*b*) The x coordinate of the center of mass of the non-uniform rod is given by:

$$x_{cm} = \frac{\int x\,dm}{\int dm} \qquad (1)$$

By symmetry:

$$y_{cm} = 0$$

The density of the long thin wire decreases with distance according to:

$$dm = (A - Bx)dx$$

Substituting for dm in equation (1) yields:

$$x_{cm} = \frac{\int_0^L x(A - Bx)dx}{\int_0^L (A - Bx)dx}$$

Evaluate these integrals to obtain:

$$x_{cm} = \frac{L}{2}\left(\frac{1 - \frac{2BL}{3A}}{1 - \frac{BL}{2A}}\right)$$

The coordinates of the center of mass of the long thin wire are

$$\boxed{\left(\frac{L}{2}\left(\frac{1-\frac{2BL}{3A}}{1-\frac{BL}{2A}}\right),0\right)}.$$

Because $A > BL$, both the numerator and denominator are positive. Because the denominator is always larger than the numerator, it follows that $x_{cm} < \frac{1}{2}L$. This makes physical sense because the mass of the rod decreases with distance and so most of it is to the left of the midpoint of the rod. Note also that if B = 0, our result predicts a uniform density (of A) and the center of mass is at the midpoint of the rod (as it should be).

Motion of the Center of Mass

113 • **[SSM]** Two 3.0-kg particles have velocities $\vec{v}_1 = (2.0\text{ m/s})\vec{i} + (3.0\text{ m/s})\vec{j}$ and $\vec{v}_1 = (4.0\text{ m/s})\vec{i} - (6.0\text{ m/s})\vec{j}$. Find the velocity of the center of mass of the system.

Picture the Problem We can use Equation 5-24 ($M\vec{v}_{cm} = \sum_i m_i\vec{v}_i$) to find the velocity of the center of mass of this system of two particles.

From Equation 5-24:

$$\vec{v}_{cm} = \frac{\sum_i m_i\vec{v}_i}{M} = \frac{m_1\vec{v}_1 + m_2\vec{v}_2}{m_1 + m_2}$$

Substitute numerical values and evaluate $\vec{v}_{cm}$:

$$\vec{v}_{cm} = \frac{(3.0\text{ kg})\left[(2.0\text{ m/s})\hat{i} + (3.0\text{ m/s})\hat{j}\right] + (3.0\text{ kg})\left[(4.0\text{ m/s})\hat{i} - (6.0\text{ m/s})\hat{j}\right]}{3.0\text{ kg} + 3.0\text{ kg}}$$

$$= \boxed{(3.0\text{ m/s})\hat{i} - (1.5\text{ m/s})\hat{j}}$$

114 • A 1500-kg car is moving westward with a speed of 20.0 m/s, and a 3000-kg truck is traveling east with a speed of 16.0 m/s. Find the velocity of the center of mass of the car-truck system.

Picture the Problem Choose a coordinate system in which east is the +x direction and use Equation 5-24 ($M\vec{v}_{cm} = \sum_i m_i\vec{v}_i$) to find the velocity of the center of mass of this system of the two cars.

From Equation 5-24:

$$\vec{v}_{cm}=\frac{\sum_i m_i\vec{v}_i}{M}=\frac{m_t\vec{v}_t+m_c\vec{v}_c}{m_t+m_c}$$

Express the velocity of the truck: $\vec{v}_t=(16.0\,\text{m/s})\hat{i}$

Express the velocity of the car: $\vec{v}_c=(-20.0\,\text{m/s})\hat{i}$

Substitute numerical values and evaluate $\vec{v}_{cm}$:

$$\vec{v}_{cm}=\frac{(3000\,\text{kg})(16.0\,\text{m/s})\,\hat{i}+(1500\,\text{kg})(-20.0\,\text{m/s})\,\hat{i}}{3000\,\text{kg}+1500\,\text{kg}}=\boxed{(4.00\,\text{m/s})\,\hat{i}}$$

115 • A force $\vec{F}$ = 12 N $\hat{i}$ is applied to the 3.0-kg ball in Figure 5-78 in Problem 103. (No forces act on the other two balls.) What is the acceleration of the center of mass of the three-ball system?

Picture the Problem The acceleration of the center of mass of the ball is related to the net external force through Newton's second law: $\vec{F}_{net,ext}=M\vec{a}_{cm}$.

Use Newton's second law to express the acceleration of the ball: $\vec{a}_{cm}=\frac{\vec{F}_{net,ext}}{M}$

Substitute numerical values and evaluate $\vec{a}_{cm}$:

$$\vec{a}_{cm}=\frac{(12\,\text{N})\hat{i}}{3.0\,\text{kg}+1.0\,\text{kg}+1.0\,\text{kg}}=\boxed{(2.4\,\text{m/s}^2)\hat{i}}$$

116 •• A block of mass *m* is attached to a string and suspended inside an otherwise empty box of mass *M*. The box rests on a scale that measures the system's weight. (*a*) If the string breaks, does the reading on the scale change? Explain your reasoning. (*b*) Assume that the string breaks and the mass *m* falls with constant acceleration *g*. Find the magnitude and direction of the acceleration of the center of mass of the box–block system. (*c*) Using the result from (*b*), determine the reading on the scale while *m* is in free-fall.

Picture the Problem Choose a coordinate system in which upward is the +*y* direction. We can use Newton's second law, $\vec{F}_{net,ext}=M\vec{a}_{cm}$, to find the acceleration of the center of mass of this two-body system.

(*a*) Yes; initially the scale reads $(M + m)g$. While the block is in free fall, the reading is Mg.

(*b*) Using Newton's second law, express the acceleration of the center of mass of the system:

$$\vec{a}_{cm} = \frac{\vec{F}_{net,ext}}{m_{tot}}$$

The box has zero acceleration. Hence:

$$\vec{a}_{cm} = -\left(\frac{mg + M(0)}{M+m}\right)\hat{j} = \boxed{-\left(\frac{mg}{M+m}\right)\hat{j}}$$

(*c*) Let F_n be the normal force exerted by the scale (the scale reading) on the box. Use Newton's second law to express the net force acting on the system while the block is falling:

$$F_{net,ext} = F_n - mg - Mg = (M+m)a_{cm}$$

Solving for F_n yields:

$$F_n = (M+m)a_{cm} + mg + Mg$$

Substitute for a_{cm} and simplify to obtain:

$$F_n = (M+m)\left(-\frac{mg}{M+m}\right) + (M+m)g$$

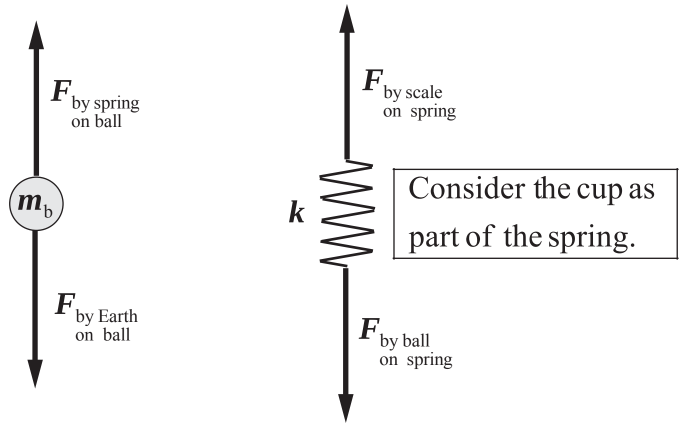
$$= \boxed{Mg}$$

as expected, given our answer to (*a*).

117 •• **[SSM]** The bottom end of a massless, vertical spring of force constant k rests on a scale and the top end is attached to a massless cup, as in Figure 5-81. Place a ball of mass m_b gently into the cup and ease it down into an equilibrium position where it sits at rest in the cup. (*a*) Draw the separate free-body diagrams for the ball and the spring. (*b)* Show that in this situation, the spring compression d is given by $d = m_b g/k$. (*c*) What is the scale reading under these conditions?

Picture the Problem (*b*) We can apply Newton's second law to the ball to find an expression for the spring's compression when the ball is at rest in the cup. (*c*) The scale reading is the force exerted by the spring on the scale and can be found from the application of Newton's second law to the cup (considered as part of the spring).

(*a*) The free-body diagrams for the ball and spring follow. Note that, because the ball has been eased down into the cup, both its speed and acceleration are zero.



(*b*) Letting the upward direction be the positive *y* direction, apply $\sum F_y = ma_y$ to the ball when it is at rest in the cup and the spring has been compressed a distance *d*:

$$F_{\substack{\text{by spring}\\\text{on ball}}} - F_{\substack{\text{by Earth}\\\text{on ball}}} = m_b a_y$$

or, because $a_y = 0$,

$$F_{\substack{\text{by spring}\\\text{on ball}}} - F_{\substack{\text{by Earth}\\\text{on ball}}} = 0 \qquad (1)$$

Because $F_{\substack{\text{by spring}\\\text{on ball}}} = kd$ and $F_{\substack{\text{by Earth}\\\text{on ball}}} = m_b g$:

$$kd - m_b g = 0 \Rightarrow d = \boxed{\frac{m_b g}{k}}$$

(*c*) Apply $\sum F_y = ma_y$ to the spring:

$$F_{\substack{\text{by scale}\\\text{on spring}}} - F_{\substack{\text{by ball}\\\text{on spring}}} = m_{\text{spring}} a_y \qquad (2)$$

or, because $a_y = 0$,

$$F_{\substack{\text{by scale}\\\text{on spring}}} - F_{\substack{\text{by ball}\\\text{on spring}}} = 0$$

Because $F_{\substack{\text{by spring}\\\text{on ball}}} = F_{\substack{\text{by ball}\\\text{on spring}}}$, adding equations (1) and (2) yields:

$$F_{\substack{\text{by scale}\\\text{on spring}}} - F_{\substack{\text{by Earth}\\\text{on ball}}} = 0$$

Solving for $F_{\substack{\text{by scale}\\\text{on spring}}}$ yields:

$$F_{\substack{\text{by scale}\\\text{on spring}}} = F_{\substack{\text{by Earth}\\\text{on ball}}} = \boxed{m_b g}$$

118 ••• In the Atwood's machine in Figure 5-82 the string passes over a fixed cylinder of mass m_c. The cylinder does not rotate. Instead, the string slides on its frictionless surface. (*a*) Find the acceleration of the center of mass of the two-block-cylinder-string system. (*b*) Use Newton's second law for systems to find the force *F* exerted by the support. (*c*) Find the tension *T* in the string connecting the blocks and show that $F = m_c g + 2T$.

Picture the Problem Assume that the object whose mass is m_1 is moving downward and take that direction to be the positive direction. We'll use Newton's second law for a system of particles to relate the acceleration of the center of mass to the acceleration of the individual particles.

(*a*) Relate the acceleration of the center of mass to m_1, m_2, m_c and their accelerations:

$$M\vec{a}_{cm} = m_1\vec{a}_1 + m_2\vec{a}_2 + m_c\vec{a}_c$$

Because m_1 and m_2 have a common acceleration of magnitude a and $a_c = 0$:

$$a_{cm} = a\left(\frac{m_1 - m_2}{m_1 + m_2 + m_c}\right)$$

From Problem 4-84 we have::

$$a = g\frac{m_1 - m_2}{m_1 + m_2}$$

Substitute to obtain:

$$a_{cm} = \left(\frac{m_1 - m_2}{m_1 + m_2}g\right)\left(\frac{m_1 - m_2}{m_1 + m_2 + m_c}\right) = \boxed{\frac{(m_1 - m_2)^2}{(m_1 + m_2)(m_1 + m_2 + m_c)}g}$$

(*b*) Use Newton's second law for a system of particles to obtain:

$$-F + Mg = Ma_{cm}$$

where $M = m_1 + m_2 + m_c$ and F is upwards.

Solve for F, substitute for a_{cm} from Part (*a*), and simplify to obtain:

$$F = Mg - Ma_{cm} = Mg - \frac{(m_1 - m_2)^2}{m_1 + m_2}g = \boxed{\left[\frac{4m_1m_2}{m_1 + m_2} + m_c\right]g}$$

(*c*) From Problem 4-84 we have:

$$T = \frac{2m_1m_2}{m_1 + m_2}g$$

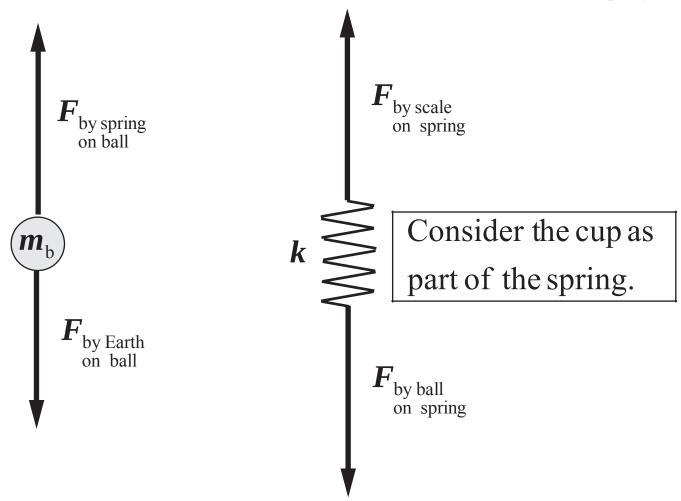
Substitute in our result from Part (*b*) and simplify to obtain:

$$F = \left[2\frac{2m_1m_2}{m_1 + m_2} + m_c\right]g = \left[2\frac{T}{g} + m_c\right]g = \boxed{2T + m_cg}$$

119 ••• Starting with the equilibrium situation in Problem 117, the whole system (scale spring, cup, and ball) is now subjected to an upward acceleration of magnitude a (for example, in an elevator). Repeat the free-body diagrams and calculations in Problem 117.

Picture the Problem Because the whole system is accelerating upward, the net upward force acting on the system must be upward. Because the spring is massless, the two forces acting on it remain equal and are oppositely directed. (*b*) We can apply Newton's second law to the ball to find an expression for the spring's compression under the given conditions. (*c*) The scale reading, as in Problem 117, is the force the scale exerts on the spring and can be found from the application of Newton's second law to the spring.

(*a*) The free-body diagrams for the ball and spring follow. Note that, because the system is accelerating upward, $F_{\substack{\text{by spring}\\\text{on ball}}} > F_{\substack{\text{by Earth}\\\text{on ball}}}$ whereas $F_{\substack{\text{by scale}\\\text{on spring}}} = F_{\substack{\text{by ball}\\\text{on spring}}}$.



(*b*) Letting the upward direction be the positive y direction, apply $\sum F_y = ma_y$ to the ball when the spring is compressed a distance d':

$$F_{\substack{\text{by spring}\\\text{on ball}}} - F_{\substack{\text{by Earth}\\\text{on ball}}} = m_b a_y \qquad (1)$$

Because $F_{\substack{\text{by spring}\\\text{on ball}}} = kd'$, $a_y = a$, and $F_{\substack{\text{by Earth}\\\text{on ball}}} = m_b g$:

$$kd' - m_b g = m_b a \Rightarrow d' = \boxed{\frac{m_b(g+a)}{k}}$$

(*c*) Apply $\sum F_y = ma_y$ to the spring:

$$F_{\substack{\text{by scale}\\\text{on spring}}} - F_{\substack{\text{by ball}\\\text{on spring}}} = 0 \qquad (2)$$

Because $F_{\substack{\text{by spring}\\\text{on ball}}} = F_{\substack{\text{by ball}\\\text{on spring}}}$ and $a_y = a$, adding equations (1) and (2) yields:

$$F_{\substack{\text{by scale}\\\text{on spring}}} - F_{\substack{\text{by Earth}\\\text{on ball}}} = m_b a$$

Solving for $F_{\substack{\text{by scale}\\\text{on spring}}}$ yields:

$$F_{\substack{\text{by scale}\\\text{on spring}}} = m_b a + F_{\substack{\text{by Earth}\\\text{on ball}}}$$

Substitute for $F_{\substack{\text{by Earth}\\\text{on ball}}}$ and simplify to obtain:

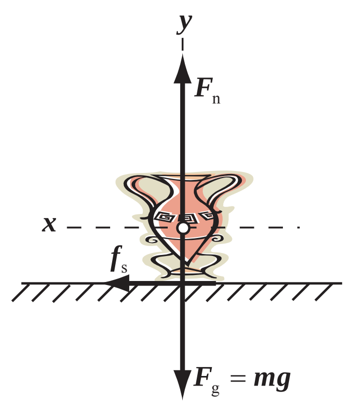
$$F_{\substack{\text{by scale}\\\text{on spring}}} = \boxed{m_b(a+g)}$$

Remarks: Note that the two forces acting on the spring and the upward force acting on the ball, while still equal, are larger (because the system is accelerating upward) than they were in Problem 117.

General Problems

120 • In designing your new house in California, you are prepared for it to withstand a maximum horizontal acceleration of 0.50g. What is the minimum coefficient of static friction between the floor and your prized Tuscan vase so that the vase does not slip on the floor under these conditions?

Picture the Problem The forces acting on the vase are the gravitational force $\vec{F}_g = m\vec{g}$ exerted by Earth, the normal force $\vec{F}_n$ exerted by the floor, and the static friction force $\vec{f}_s$, also exerted by the floor. We can apply Newton's second law to find the minimum coefficient of static friction that will prevent the vase from slipping.



Apply $\sum\vec{F} = m\vec{a}$ to the vase to obtain:

$$\sum F_x = f_s = ma_x \qquad (1)$$

and

$$\sum F_y = F_n - mg = 0$$

Relate the static friction force $\vec{f}_s$ to the minimum coefficient of static friction $\mu_{s,min}$ that will prevent the vase from slipping:

$$f_s = \mu_{s,min} F_n$$

or, because $F_n = mg$,

$$f_s = \mu_{s,min} mg$$

Substituting for f_s in equation (1) yields:

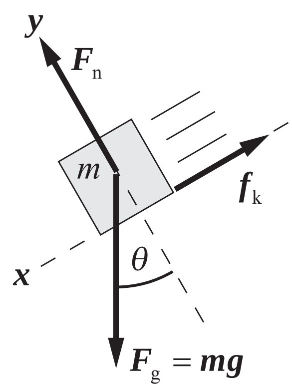
$$\mu_{s,\min} mg = ma_x \Rightarrow \mu_{s,\min} = \frac{a_x}{g}$$

Because $a_x = 0.50g$:

$$\mu_{s,\min} = \frac{0.50g}{g} = \boxed{0.50}$$

121 • A 4.5-kg block slides down an inclined plane that makes an angle of 28° with the horizontal. Starting from rest, the block slides a distance of 2.4 m in 5.2 s. Find the coefficient of kinetic friction between the block and plane.

Picture the Problem The forces that act on the block as it slides down the incline are shown on the free-body diagram to the right. The acceleration of the block can be determined from the distance-and-time information given in the problem. The application of Newton's second law to the block will lead to an expression for the coefficient of kinetic friction as a function of the block's acceleration and the angle of the incline.



Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\sum F_x = mg\sin\theta - f_k = ma_x \quad (1)$$

and

$$\sum F_y = F_n - mg\cos\theta = 0 \quad (2)$$

Set $f_k = \mu_k F_n$ in equation (1) to obtain:

$$mg\sin\theta - \mu_k F_n = ma_x \quad (3)$$

Solve equation (2) for F_n and substitute in equation (3) to obtain:

$$mg\sin\theta - \mu_k mg\cos\theta = ma_x$$

Solving for μ_k yields:

$$\mu_k = \frac{g\sin\theta - a_x}{g\cos\theta} \quad (4)$$

Using a constant-acceleration equation, relate the distance the block slides to its sliding time:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$

or, because $v_{0x} = 0$,

$$\Delta x = \tfrac{1}{2}a_x(\Delta t)^2 \Rightarrow a_x = \frac{2\Delta x}{(\Delta t)^2}$$

Substitute for a_x in equation (4) to obtain:

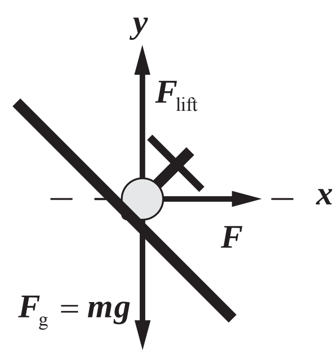
$$\mu_k = \frac{g\sin\theta - \dfrac{2\Delta x}{(\Delta t)^2}}{g\cos\theta}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{(9.81\ \text{m/s}^2)\sin 28° - \dfrac{2(2.4\ \text{m})}{(5.2\ \text{s})^2}}{(9.81\ \text{m/s}^2)\cos 28°} = \boxed{0.51}$$

122 •• You plan to fly a model airplane of mass 0.400 kg that is attached to a horizontal string. The plane will travel in a horizontal circle of radius 5.70 m. (Assume the weight of the plane is balanced by the upward "lift" force of the air on the wings of the plane.) The plane will make 1.20 revolutions every 4.00 s. (*a*) Find the speed at which you must fly the plane. (*b*) Find the force exerted on your hand as you hold the string (assume the string is massless).

Picture the Problem The force exerted on your hand as you hold the string is the reaction force to the tension $\vec{F}$ in the string and, hence, has the same magnitude. The speed of the plane can be calculated from the data concerning the radius of its path and the time it takes to make one revolution. The application of Newton's second law will give us the tension F in the string.



(*a*) Express the speed of the airplane in terms of the circumference of the circle in which it is flying and its period:

$$v = \frac{2\pi r}{T}$$

Substitute numerical values and evaluate v:

$$v = \frac{2\pi(5.70\ \text{m})}{\dfrac{4.00\ \text{s}}{1.20\ \text{rev}}} = \boxed{10.7\ \text{m/s}}$$

(*b*) Apply $\sum F_x = ma_x$ to the model airplane:

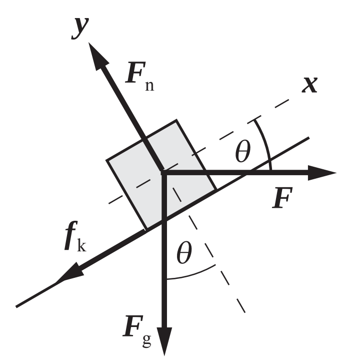
$$F = m\frac{v^2}{r}$$

Substitute numerical values and evaluate F:

$$F=\frac{(0.400\,\text{kg})(10.74\,\text{m/s})^2}{5.70\,\text{m}}=\boxed{8.10\,\text{N}}$$

123 •• Your moving company is to load a crate of books on a truck with the help of some planks that slope upward at 30.0º. The mass of the crate is 100 kg, and the coefficient of sliding friction between it and the planks is 0.500. You and your employees push *horizontally* with a combined net force $\vec{F}$. Once the crate has started to move, how large must F be in order to keep the crate moving at constant speed?

Picture the Problem The free-body diagram shows the forces acting on the crate of books. The kinetic friction force opposes the motion of the crate up the incline. Because the crate is moving at constant speed in a straight line, its acceleration is zero. We can determine F by applying Newton's second law to the crate, substituting for f_k, eliminating the normal force, and solving for the required force.



Apply $\sum\vec{F}=m\vec{a}$ to the crate, with both a_x and a_y equal to zero, to the crate:

$$\sum F_x=F\cos\theta-f_k-mg\sin\theta=0$$

and

$$\sum F_y=F_n-F\sin\theta-mg\cos\theta=0$$

Because $f_k=\mu_kF_n$, the x-equation becomes:

$$F\cos\theta-\mu_kF_n-mg\sin\theta=0 \quad (1)$$

Solving the y-equation for F_n yields:

$$F_n=F\sin\theta+mg\cos\theta$$

Substitute for F_n in equation (1) and solve for F to obtain:

$$F=\frac{mg(\sin\theta+\mu_k\cos\theta)}{\cos\theta-\mu_k\sin\theta}$$

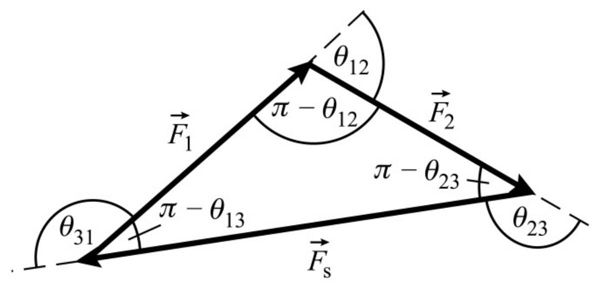
Substitute numerical values and evaluate F:

$$F=\frac{(100\,\text{kg})(9.81\,\text{m/s}^2)(\sin30°+(0.500)\cos30.0°)}{\cos30.0°-(0.500)\sin30°}=\boxed{1.49\,\text{kN}}$$

124 •• Three forces act on an object in static equilibrium (Figure 5-83). (*a*) If F_1, F_2, and F_3 represent the magnitudes of the forces acting on the object, show that $F_1/\sin\theta_{23} = F_2/\sin\theta_{31} = F_3/\sin\theta_{12}$. (*b*) Show that $F_1^2 = F_2^2 + F_3^2 + 2F_2F_3\cos\theta_{23}$.

Picture the Problem The fact that the object is in static equilibrium under the influence of the three forces means that $\vec{F}_1 + \vec{F}_2 + \vec{F}_3 = 0$. Drawing the corresponding force triangle will allow us to relate the forces to the angles between them through the law of sines and the law of cosines.

(*a*) Using the fact that the object is in static equilibrium, redraw the force diagram connecting the forces head-to-tail:



Appling the law of sines to the triangle yields:

$$\frac{F_1}{\sin(\pi - \theta_{23})} = \frac{F_2}{\sin(\pi - \theta_{13})} = \frac{F_3}{\sin(\pi - \theta_{12})}$$

Use the trigonometric identity $\sin(\pi - \alpha) = \sin\alpha$ to obtain:

$$\boxed{\frac{F_1}{\sin\theta_{23}} = \frac{F_2}{\sin\theta_{13}} = \frac{F_3}{\sin\theta_{12}}}$$

(*b*) Appling the law of cosines to the triangle yields:

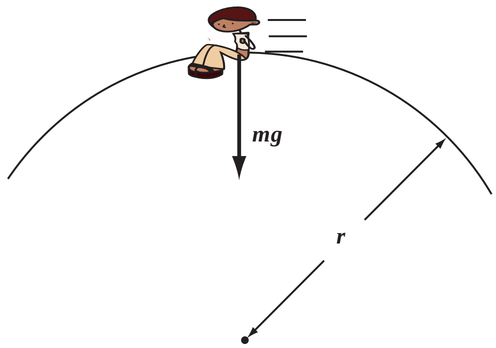
$$F_1^2 = F_2^2 + F_3^2 - 2F_2F_3\cos(\pi - \theta_{23})$$

Use the trigonometric identity $\cos(\pi - \alpha) = -\cos\alpha$ to obtain:

$$F_1^2 = \boxed{F_2^2 + F_3^2 + 2F_2F_3\cos\theta_{23}}$$

125 •• In a carnival ride, you sit on a seat in a compartment that rotates with constant speed in a vertical circle of radius 5.0 m. The ride is designed so your head always points toward the center of the circle. (*a*) If the ride completes one full circle in 2.0 s, find the direction and magnitude of your acceleration. (*b*) Find the slowest rate of rotation (in other words, the longest time T_m to complete one full circle) if the seat belt is to exert no force on you at the top of the ride.

Picture the Problem We can calculate your acceleration from your speed that, in turn, is a function of the period of the motion. To determine the longest period of the motion, we focus our attention on the situation at the very top of the ride when the seat belt is exerting no force on you. We can use Newton's second law to relate the period of the motion to your acceleration and speed.



(*a*) Because the motion is at constant speed, your acceleration is entirely radial and is given by:

$$a_c = \frac{v^2}{r}$$

Express your speed as a function of the radius of the circle and the period of the motion:

$$v = \frac{2\pi r}{T}$$

Substitute for v in the expression for a_c and simplify to obtain:

$$a_c = \frac{4\pi^2 r}{T^2}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{4\pi^2(5.0\,\text{m})}{(2.0\,\text{s})^2} = \boxed{49\,\text{m/s}^2}$$

(*b*) Apply $\sum \vec{F} = m\vec{a}$ to yourself when you are at the top of the circular path and the seat belt is exerting no force on you:

$$\sum F_r = mg = m\frac{v^2}{r} \Rightarrow v = \sqrt{gr}$$

Express the period of your motion as a function of the radius of the circle:

$$T_m = \frac{2\pi r}{v}$$

Substituting for v and simplifying yields:

$$T_m = \frac{2\pi r}{\sqrt{gr}} = 2\pi\sqrt{\frac{r}{g}}$$

The slowest rate of rotation is the reciprocal of T_m:

$$T_m^{-1} = \frac{1}{2\pi}\sqrt{\frac{g}{r}}$$

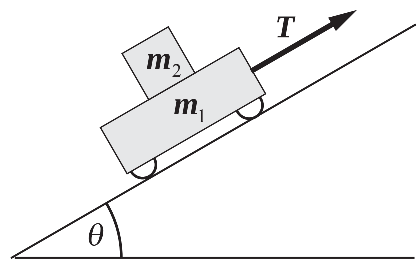
Substitute numerical values and evaluate $\boldsymbol{T}_{\mathrm{m}}^{-1}$:

$$T_{\mathrm{m}}^{-1} = \frac{1}{2\pi}\sqrt{\frac{9.81\,\mathrm{m/s^2}}{5.0\,\mathrm{m}}}$$
$$= 0.2229\,\mathrm{s}^{-1} \times \frac{60\,\mathrm{s}}{\mathrm{min}}$$
$$\approx \boxed{13\,\mathrm{rev/min}}$$

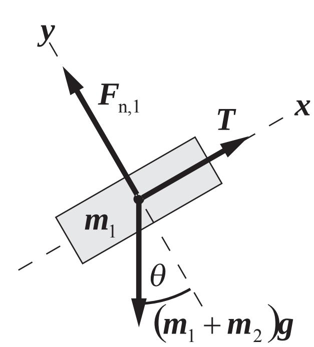
Remarks: You are ″weightless″ under the conditions described in Part (*b*).

126 •• A flat-topped toy cart moves on frictionless wheels, pulled by a rope under tension T. The mass of the cart is m_1. A load of mass m_2 rests on top of the cart with the coefficient of static friction μ_s between the cart and the load. The cart is pulled up a ramp that is inclined at angle θ above the horizontal. The rope is parallel to the ramp. What is the maximum tension T that can be applied without causing the load to slip?

Picture the Problem The pictorial representation to the right shows the cart and its load on the inclined plane. The load will not slip provided its maximum acceleration is not exceeded. We can find that maximum acceleration by applying Newton's second law to the load. We can then apply Newton's second law to the cart-plus-load system to determine the tension in the rope when the system is experiencing its maximum acceleration.



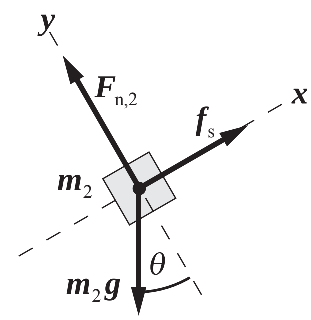
Draw the free-body diagram for the cart and its load:



Apply $\sum F_x = ma_x$ to the cart plus its load:

$$T - (m_1 + m_2)g\sin\theta = (m_1 + m_2)a_{x,\max} \qquad (1)$$

Draw the free-body diagram for the load of mass m_2 on top of the cart:



Apply $\sum\vec{F} = m\vec{a}$ to the load on top of the cart:

$$\sum F_x = f_{s,max} - m_2 g\sin\theta = m_2 a_{x,max}$$

and

$$\sum F_y = F_{n,2} - m_2 g\cos\theta = 0$$

Because $f_{s,max} = \mu_s F_{n,2}$, the x equation becomes:

$$\mu_s F_{n,2} - m_2 g\sin\theta = m_2 a_{x,max} \qquad (2)$$

Solving the y equation for $F_{n,2}$ yields:

$$F_{n,2} = m_2 g\cos\theta$$

Substitute for $F_{n,2}$ in equation (2) to obtain:

$$\mu_s m_2 g\cos\theta - m_2 g\sin\theta = m_2 a_{x,max}$$

Solving for $a_{x,max}$ and simplifying yields:

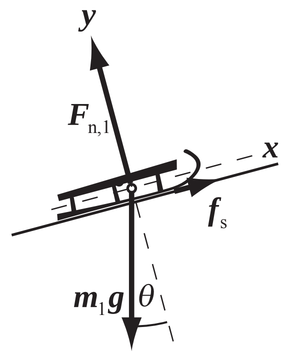
$$a_{x,max} = g(\mu_s\cos\theta - \sin\theta) \qquad (3)$$

Substitute for $a_{x,max}$ in equation (1) and solve for T to obtain:

$$T = \boxed{(m_1 + m_2)g\mu_s\cos\theta}$$

127 ••• A sled weighing 200 N that is held in place by static friction, rests on a 15º incline (Figure 5-84). The coefficient of static friction between the sled and the incline is 0.50. (*a*) What is the magnitude of the normal force on the sled? (*b*) What is the magnitude of the static frictional force on the sled? (*c*) The sled is now pulled up the incline at constant speed by a child walking up the incline ahead of the sled. The child weighs 500 N and pulls on the rope with a constant force of 100 N. The rope makes an angle of 30º with the incline and has negligible mass. What is the magnitude of the kinetic frictional force on the sled? (*d*) What is the coefficient of kinetic friction between the sled and the incline? (*e*) What is the magnitude of the force exerted on the child by the incline?

Picture the Problem The free-body diagram for the sled while it is held stationary by the static friction force is shown to the right. We can solve this problem by repeatedly applying Newton's second law under the conditions specified in each part of the problem.



(*a*) Apply $\sum F_y = ma_y$ to the sled: $F_{n,1} - m_1 g\cos\theta = 0$

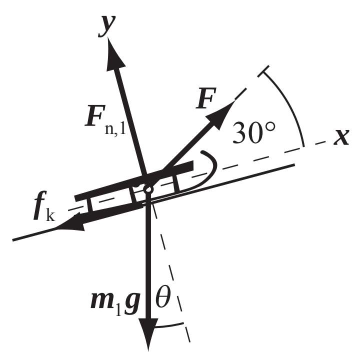
Solve for $F_{n,1}$: $F_{n,1} = m_1 g\cos\theta$

Substitute numerical values and evaluate $F_{n,1}$: $F_{n,1} = (200\ \text{N})\cos 15° = \boxed{0.19\ \text{kN}}$

(*b*) Apply $\sum F_x = ma_x$ to the sled: $f_s - m_1 g\sin\theta = 0 \Rightarrow f_s = m_1 g\sin\theta$

Substitute numerical values and evaluate f_s: $f_s = (200\ \text{N})\sin 15° = \boxed{52\ \text{N}}$

(*c*) Draw the free-body diagram for the sled when it is moving up the incline at constant speed:



Apply $\sum F_x = 0$ to the sled to obtain: $F\cos 30° - m_1 g\sin\theta - f_k = 0$

Solving for f_k yields: $f_k = F\cos 30° - m_1 g\sin\theta$

Substitute numerical values and evaluate f_k:

$$f_k = (100\ \text{N})\cos 30° - (200\ \text{N})\sin 15° = 34.84\ \text{N} = \boxed{35\ \text{N}}$$

(*d*) The coefficient of kinetic friction between the sled and the incline is given by:

$$\mu_k = \frac{f_k}{F_{n,1}} \qquad (1)$$

Apply $\sum F_y = 0$ to the sled to obtain:

$$F_{n,1} + F\sin 30° - m_1 g\cos\theta = 0$$

Solve for $F_{n,1}$:

$$F_{n,1} = m_1 g\cos\theta - F\sin 30°$$

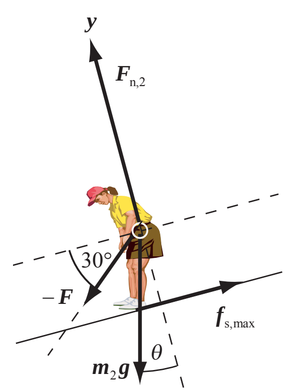
Substituting for $F_{n,1}$ in equation (1) yields:

$$\mu_k = \frac{f_k}{m_1 g\cos\theta - F\sin 30°}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{34.84\text{ N}}{(200\text{ N})\cos 15° - (100\text{ N})\sin 30°} = \boxed{0.24}$$

(*e*) Draw the free body diagram for the child:



Express the net force F_c exerted on the child by the incline:

$$F_c = \sqrt{F_{n2}^2 + f_{s,max}^2} \qquad (1)$$

Noting that the child is stationary, apply $\sum \vec{F} = m\vec{a}$ to the child:

$$\sum F_x = f_{s,max} - F\cos 30° - m_2 g\sin 15° = 0$$

and

$$\sum F_y = F_{n2} - m_2 g\cos 15° - F\sin 30° = 0$$

Solve the x equation for $f_{s,max}$ and the y equation for $F_{n,2}$:

$$f_{s,max} = F\cos 30° + m_2 g\sin 15°$$

and

$$F_{n,2} = m_2 g\cos 15° + F\sin 30°$$

Substitute numerical values and evaluate $f_{s,max}$ and $F_{n,2}$:

$$f_{s,max} = (100\,N)\cos 30° + (500\,N)\sin 15° = 216.0\,N$$

and

$$F_{n,2} = (500\,N)\cos 15° + (100\,N)\sin 30° = 533.0\,N$$

Substitute numerical values in equation (1) and evaluate F:

$$F_c = \sqrt{(216.0\,N)^2 + (533.0\,N)^2} = \boxed{0.58\,kN}$$

128 •• In 1976, Gerard O'Neill proposed that large space stations be built for human habitation in orbit around Earth and the moon. Because prolonged free-fall has adverse medical effects, he proposed making the stations in the form of long cylinders and spinning them around the cylinder axis to provide the inhabitants with the sensation of gravity. One such O'Neill colony is to be built 5.0 miles long, with a diameter of 0.60 mi. A worker on the inside of the colony would experience a sense of ″gravity,″ because he would be in an accelerated frame of reference due to the rotation. (*a*) Show that the ″acceleration of gravity″ experienced by the worker in the O'Neill colony is equal to his centripetal acceleration. (*Hint:* Consider someone ″looking in″ from outside the colony.) (*b*) If we assume that the space station is composed of several decks that are at varying distances (radii) from the axis of rotation, show that the ″acceleration of gravity″ becomes weaker the closer the worker gets to the axis. (*c*) How many revolutions per minute would this space station have to make to give an ″acceleration of gravity″ of 9.8 m/s^2 at the outermost edge of the station?

Picture the Problem Let v represent the speed of rotation of the station, and r the distance from the center of the station. Because the O'Neill colony is, presumably, in deep space, the only acceleration one would experience in it would be that due to its rotation.

(*a*) The acceleration of anyone who is standing inside the station is $a = v^2/r$. This acceleration is directed toward the axis of rotation. If someone inside the station drops an apple, the apple will not have any forces acting on it once released, but will move along a straight line at constant speed. However, from the point of view of our observer inside the station, if he views himself as unmoving, the apple is perceived to have an acceleration of v^2/r directed away from the axis of rotation (a "centrifugal" acceleration).

(*b*) Each deck must rotate about the central axis with the same period T. Relate the speed of a person on a particular deck to his/her distance r from the center:

$$v = \frac{2\pi r}{T}$$

Express the "acceleration of gravity" perceived by someone a distance r from the center:

$$a_c = \frac{v^2}{r} = \frac{4\pi^2 r}{T^2}$$, a result that tells us that the "acceleration of gravity" decreases as r decreases.

(c) Relate the desired acceleration to the radius of the space station and its period:

$$a = \frac{4\pi^2 r}{T^2} \Rightarrow T = \sqrt{\frac{4\pi^2 r}{a}}$$

Substitute numerical values and evaluate T:

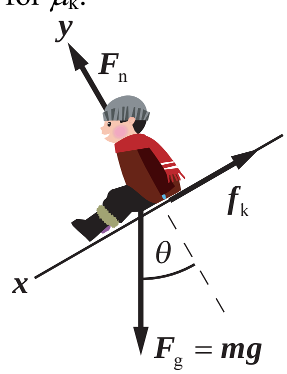
$$T = \sqrt{\frac{4\pi^2\left(0.30\,\text{mi} \times \frac{1.609\,\text{km}}{\text{mi}}\right)}{9.8\,\text{m/s}^2}} = 44\,\text{s} \approx 0.74\,\text{min}$$

Take the reciprocal of this time to find the number of revolutions per minute Babylon 5 has to make in order to provide this "Earth-like" acceleration:

$$T^{-1} = \boxed{1.4\,\text{rev/min}}$$

129 •• A child of mass m slides down a slide inclined at 30º in time t_1. The coefficient of kinetic friction between her and the slide is μ_k. She finds that if she sits on a small sled (also of mass m) with frictionless runners, she slides down the same slide in time $\frac{1}{2}t_1$. Find μ_k.

Picture the Problem The following free-body diagram shows the forces acting on the child as she slides down the incline. We'll first use Newton's second law to derive an expression for μ_k in terms of her acceleration and then use Newton's second law to find her acceleration when riding the frictionless cart. Using a constant-acceleration equation, we'll relate these two accelerations to her descent times and solve for her acceleration when sliding. Finally, we can use this acceleration in the expression for μ_k.



Apply $\sum \vec{F} = m\vec{a}$ to the child as she slides down the incline:

$$\sum F_x = mg\sin\theta - f_k = ma_{1,x}$$
and
$$\sum F_y = F_n - mg\cos\theta = 0$$

Because $f_k = \mu_k F_n$, the x-equation can be written:

$$mg\sin\theta - \mu_k F_n = ma_{1,x} \qquad (1)$$

Solving the y-equation for F_n yields:

$$F_n = mg\cos\theta$$

Substitute for F_n in equation (1) to obtain:

$$mg\sin\theta - \mu_k mg\cos\theta = ma_{1,x}$$

Solving for μ_k yields:

$$\mu_k = \tan 30° - \frac{a_{1,x}}{g\cos 30°} \qquad (2)$$

Apply $\sum F_x = ma_x$ to the child as she rides the frictionless cart down the incline and solve for her acceleration $a_{2,x}$:

$$mg\sin 30° = ma_{2,x}$$
and
$$a_{2,x} = g\sin 30°$$

Letting s represent the distance she slides down the incline, use a constant-acceleration equation to relate her sliding times to her accelerations and distance traveled down the slide :

$$s = v_{0x}t_1 + \tfrac{1}{2}a_{1,x}t_1^2 \text{ where } v_{0x} = 0$$
and
$$s = v_{0x}t_2 + \tfrac{1}{2}a_{2,x}t_2^2 \text{ where } v_{0x} = 0$$

Equate these expressions, substitute $t_2 = \frac{1}{2}t_1$ and solve for $a_{1,x}$:

$$a_{1,x} = \tfrac{1}{4}a_{2,x} = \tfrac{1}{4}g\sin 30°$$

Substitute for $a_{1,x}$ in equation (2) to obtain:

$$\mu_k = \tan 30° - \frac{\frac{1}{4}g\sin 30°}{g\cos 30°} = \tfrac{3}{4}\tan 30°$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \tfrac{3}{4}\tan 30° = \boxed{0.43}$$

130 ••• The position of a particle of mass $m = 0.80$ kg as a function of time is given by $\vec{r} = x\hat{i} + y\hat{j} = (R\sin\omega t)\hat{i} + (R\cos\omega t)\hat{j}$, where $R = 4.0$ m and $\omega = 2\pi\,\text{s}^{-1}$. (*a*) Show that the path of this particle is a circle of radius R, with its center at the origin of the xy plane. (*b*) Compute the velocity vector. Show that $v_x/v_y = -y/x$.

(*c*) Compute the acceleration vector and show that it is directed toward the origin and has the magnitude v^2/R. (*d*) Find the magnitude and direction of the net force acting on the particle.

Picture the Problem The path of the particle is a circle if *r* is constant. Once we have shown that it is, we can calculate its value from its components and determine the particle's velocity and acceleration by differentiation. The direction of the net force acting on the particle can be determined from the direction of its acceleration.

(*a*) Express the magnitude of $\vec{r}$ in terms of its components:

$$r = \sqrt{r_x^2 + r_y^2}$$

Evaluate *r* with $r_x = R\sin\omega t$ and $r_y = R\cos\omega t$:

$$r = \sqrt{[R\sin\omega t]^2 + [R\cos\omega t]^2}$$
$$= \sqrt{R^2\left(\sin^2\omega t + \cos^2\omega t\right)} = R$$

This result shows that the path of the particle is a circle of radius *R* centered at the origin.

(*b*) Differentiate $\vec{r}$ with respect to time to obtain $\vec{v}$:

$$\vec{v} = \frac{d\vec{r}}{dt} = [R\omega\cos\omega t]\,\hat{i} + [-R\omega\sin\omega t]\,\hat{j}$$
$$= \boxed{[(8.0\pi\cos 2\pi t)\text{m/s}]\,\hat{i} - [(8.0\pi\sin 2\pi t)\text{m/s}]\,\hat{j}}$$

Express the ratio $\dfrac{v_x}{v_y}$:

$$\frac{v_x}{v_y} = \frac{8.0\pi\cos\omega t}{-8.0\pi\sin\omega t} = -\cot\omega t \quad (1)$$

Express the ratio $-\dfrac{y}{x}$:

$$-\frac{y}{x} = -\frac{R\cos\omega t}{R\sin\omega t} = -\cot\omega t \quad (2)$$

From equations (1) and (2) we have:

$$\boxed{\frac{v_x}{v_y} = -\frac{y}{x}}$$

(*c*) Differentiate $\vec{v}$ with respect to time to obtain $\vec{a}$:

$$\vec{a} = \frac{d\vec{v}}{dt} = \boxed{\left[\left(-16\pi^2\text{m/s}^2\right)\sin\omega t\right]\hat{i} + \left[\left(-16\pi^2\text{m/s}^2\right)\cos\omega t\right]\hat{j}}$$

Factor $-4.0\pi^2/\text{s}^2$ from $\vec{a}$ to obtain:

$$\vec{\boldsymbol{a}} = \left(-4.0\boldsymbol{\pi}^2\ \text{s}^{-2}\right)\left[\left(4.0\sin\boldsymbol{\omega t}\right)\hat{\boldsymbol{i}} + \left(4.0\cos\boldsymbol{\omega t}\right)\hat{\boldsymbol{j}}\right] = \boxed{\left(-4.0\boldsymbol{\pi}^2\ \text{s}^{-2}\right)\vec{\boldsymbol{r}}}$$

Because $\vec{\boldsymbol{a}}$ is in the opposite direction from $\vec{\boldsymbol{r}}$, it is directed toward the center of the circle in which the particle is traveling.

Find the ratio $\dfrac{v^2}{R}$:

$$a = \frac{v^2}{R} = \frac{\left(8.0\pi\ \text{m/s}\right)^2}{4.0\,\text{m}} = \boxed{16\pi^2\ \text{m/s}^2}$$

(*d*) Apply $\sum\vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to the particle:

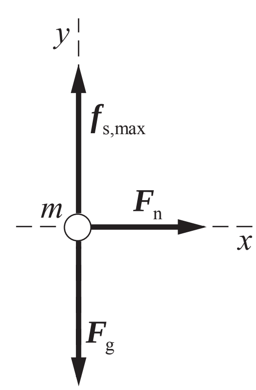
$$F_{\text{net}} = ma = \left(0.80\,\text{kg}\right)\left(16\pi^2\ \text{m/s}^2\right) = \boxed{13\pi^2\ \text{N}}$$

Because the direction of $\vec{\boldsymbol{F}}_{\text{net}}$ is the same as that of $\vec{\boldsymbol{a}}$, $\vec{\boldsymbol{F}}_{\text{net}}$ is toward the center of the circle.

131 ••• You are on an amusement park ride with your back against the wall of a spinning vertical cylinder. The floor falls away and you are held up by static friction. Assume your mass is 75 kg. (*a*) Draw a free-body diagram of yourself. (*b*) Use this diagram with Newton's laws to determine the force of friction on you. (*c*) The radius of the cylinder is 4.0 m and the coefficient of static friction between you and the wall is 0.55. What is the minimum number of revolutions per minute necessary to prevent you from sliding down the wall? Does this answer hold only for you? Will other, more massive, patrons fall downward? Explain.

Picture the Problem The application of Newton's second law and the definition of the maximum static friction force will be used to determine the period T of the motion. The reciprocal of the period will give us the minimum number of revolutions required per unit time to hold you in place.

(*a*) The free-body diagram showing the forces acting on you when you are being held in place by the maximum static friction force is shown to the right.



(*b*) Apply $\sum \vec{F} = m\vec{a}$ to yourself while you are held in place by friction:

$$\sum F_x = F_n = m\frac{v^2}{r} \qquad (1)$$

and

$$\sum F_y = f_{s,max} - mg = 0 \qquad (2)$$

Solve equation (2) for $f_{s,max}$:

$$f_{s,max} = mg$$

Substitute numerical values and evaluate $f_{s,max}$:

$$f_{s,max} = (75\text{ kg})(9.81\text{ m/s}^2) = \boxed{0.74\text{ kN}}$$

(*c*) The number of revolutions per minute *N* is the reciprocal of the period in minutes:

$$N = \frac{1}{T} \qquad (3)$$

Because $f_{s,max} = \mu_s F_n$, equation (1) can be written:

$$\frac{f_{s,max}}{\mu_s} = \frac{mg}{\mu_s} = m\frac{v^2}{r} \qquad (4)$$

Your speed is related to the period of your motion:

$$v = \frac{2\pi r}{T}$$

Substitute for *v* in equation (4) to obtain:

$$\frac{mg}{\mu_s} = m\frac{\left(\frac{2\pi r}{T}\right)^2}{r} = \frac{4\pi^2 mr}{T^2}$$

Solving for *T* yields:

$$T = 2\pi\sqrt{\frac{\mu_s r}{g}}$$

Substitute for *T* in equation (3) to obtain:

$$N = \frac{1}{2\pi\sqrt{\frac{\mu_s r}{g}}} = \frac{1}{2\pi}\sqrt{\frac{g}{\mu_s r}}$$

Substitute numerical values and evaluate *N*:

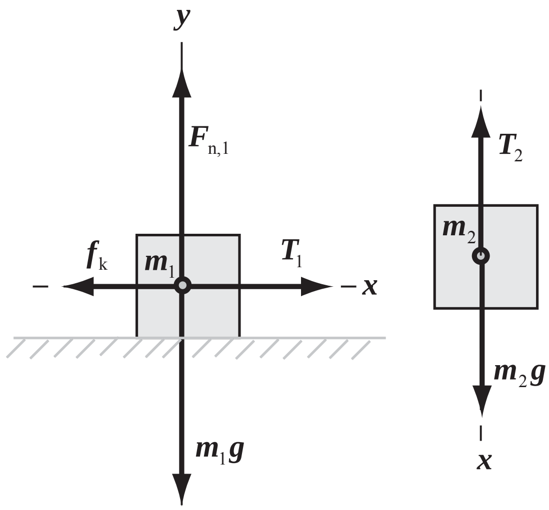
$$N = \frac{1}{2\pi}\sqrt{\frac{9.81\text{ m/s}^2}{(0.55)(4.0\text{ m})}} = 0.336\text{ rev/s}$$

$$= \boxed{20\text{ rev/min}}$$

Because your mass does not appear in the expression for *N,* this result holds for all patrons, regardless of their mass.

132 ••• A block of mass m_1 is on a horizontal table. The block is attached to a 2.5-kg block (m_2) by a light string that passes over a pulley at the edge of the table. The block of mass m_2 dangles 1.5 m above the ground (Figure 5-85). The string that connects them passes over a frictionless, massless pulley. This system is released from rest at $t = 0$ and the 2.5-kg block strikes the ground at $t = 0.82$ s. The system is now placed in its initial configuration and a 1.2-kg block is placed on top of the block of mass m_1. Released from rest, the 2.5-kg block now strikes the ground 1.3 s later. Determine the mass m_1 and the coefficient of kinetic friction between the block whose mass is m_1 and the table.

Picture the Problem The free-body diagrams below show the forces acting on the blocks whose masses are m_1 and m_2. The application of Newton's second law and the use of a constant-acceleration equation will allow us to find a relationship between the coefficient of kinetic friction and m_1. The repetition of this procedure with the additional block on top of the block whose mass is m_1 will lead us to a second equation that, when solved simultaneously with the former equation, leads to a quadratic equation in m_1. Finally, its solution will allow us to substitute in an expression for μ_k and determine its value.



Using a constant-acceleration equation, relate the displacement of the system in its first configuration as a function of its acceleration and fall time:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_{1x}(\Delta t)^2$$

or, because $v_{0x} = 0$,

$$\Delta x = \tfrac{1}{2}a_{x,1}(\Delta t)^2 \Rightarrow a_{x,1} = \frac{2\Delta x}{(\Delta t)^2}$$

Substitute numerical values and evaluate $a_{x,1}$:

$$a_{x,1} = \frac{2(1.5\,\text{m})}{(0.82\,\text{s})^2} = 4.4616\,\text{m/s}^2$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$$m_2 g - T_1 = m_2 a_{x,1} \Rightarrow T_1 = m_2(g - a_{1x})$$

Substitute numerical values and evaluate T_1:

$$T_1 = (2.5\,\text{kg})(9.81\,\text{m/s}^2 - 4.4616\,\text{m/s}^2) = 13.371\,\text{N}$$

Apply $\sum \vec{F} = m\vec{a}$ to the block whose mass is m_1:

$$\sum F_x = T_1 - f_\text{k} = m_1 a_{x,1}$$
and
$$\sum F_y = F_{\text{n},1} - m_1 g = 0$$

Using $f_\text{k} = \mu_\text{k} F_\text{n}$, eliminate F_n between the two equations to obtain:

$$T_1 - \mu_\text{k} m_1 g = m_1 a_{x,1} \quad (1)$$

Find the acceleration $a_{x,2}$ for the second run:

$$a_{x,2} = \frac{2\Delta x}{(\Delta t)^2} = \frac{2(1.5\,\text{m})}{(1.3\,\text{s})^2} = 1.775\,\text{m/s}^2$$

T_2 is given by:

$$T_2 = m_2(g - a_{x,2}) = (2.5\,\text{kg})(9.81\,\text{m/s}^2 - 1.775\,\text{m/s}^2) = 20.1\,\text{N}$$

Apply $\sum F_x = ma_x$ to the system with the 1.2-kg block in place:

$$T_2 - \mu_\text{k}(m_1 + 1.2\,\text{kg})g = (m_1 + 1.2\,\text{kg})a_{x,2} \quad (2)$$

Solve equation (1) for μ_k:

$$\mu_\text{k} = \frac{T_1 - m_1 a_{x,1}}{m_1 g} \quad (3)$$

Substitute for μ_k in equation (2) and simplify to obtain the quadratic equation in m_1:

$$2.686 m_1^2 + 9.940 m_1 - 16.05 = 0$$

Use your graphing calculator or the quadratic formula to obtain:

$$m_1 = 1.215\,\text{kg} = \boxed{1.2\,\text{kg}}$$

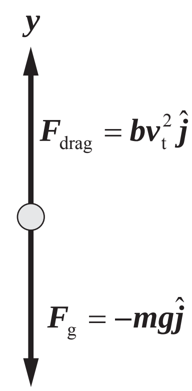
Substitute numerical values in equation (3) and evaluate μ_k:

$$\mu_\text{k} = \frac{13.375\,\text{N} - (1.215\,\text{kg})(4.4616\,\text{m/s}^2)}{(1.215\,\text{kg})(9.81\,\text{m/s}^2)} = \boxed{0.67}$$

133 ••• Sally claims flying squirrels do not really fly; they jump and use folds of skin that connect their forelegs and their back legs like a parachute to allow them to glide from tree to tree. Liz decides to test Sally's hypothesis by calculating the terminal speed of a falling outstretched flying squirrel. If the constant b in the drag force is proportional to the area of the object facing the air

flow, use the results of Example 5-8 and some assumptions about the size of the squirrel to estimate its terminal (downward) speed. Is Sally's claim supported by Liz's calculation?

Picture the Problem A free-body diagram showing the forces acting on the squirrel under terminal-speed conditions is shown to the right. We'll assume that b is proportional to the squirrel's frontal area and that this area is about 0.1 that of a human being. Further, we'll assume that the mass of a squirrel is about 1.0 kg. Applying Newton's second law will lead us to an expression for the squirrel's terminal speed.



Apply $\sum F_y = ma_y$ to the squirrel:

$$F_d - F_g = ma_y$$

or, because $a_y = 0$,

$$F_d - F_g = 0$$

Substituting for F_d and F_g yields:

$$bv_t^2 - mg = 0 \Rightarrow v_t = \sqrt{\frac{mg}{b}} \qquad (1)$$

Assuming that $A_{\text{squirrel}} = (0.1)A_{\text{human}}$:

$$b = (0.1)b_{\text{human}}$$

From Example 5-8:

$$b_{\text{human}} = 0.251\,\text{kg/m}$$

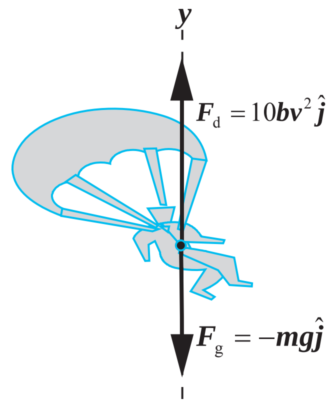
Substitute numerical values in equation (1) and evaluate v_t:

$$v_t = \sqrt{\frac{(1.0\,\text{kg})(9.81\,\text{m/s}^2)}{(0.1)(0.251\,\text{kg/m})}} \approx \boxed{20\,\text{m/s}}$$

Because the squirrel's terminal speed is approximately 80 km/h and this value is less than half that of the skydiver in Example 5-8, Sally's claim seems to be supported by Liz's calculation.

134 ••• After a parachutist jumps from an airplane (but before he pulls the rip cord to open his parachute), a downward speed of up to 180 km/h can be reached. When the parachute is finally opened, the drag force is increased by about a factor of 10, and this can create a large jolt on the jumper. Suppose this jumper falls at 180 km/h before opening his chute. (*a*) Determine the parachutist's acceleration when the chute is just opened, assuming his mass is 60 kg. (*b*) If rapid accelerations greater than 5.0g can harm the structure of the human body, is this a safe practice?

Picture the Problem The free-body diagram shows the drag force $\vec{F}_d$ exerted by the air and the gravitational force $\vec{F}_g$ exerted by Earth acting on on the parachutist just after his chute has opened. We can apply Newton's second law to the parachutist to obtain an expression for his acceleration as a function of his speed and then evaluate this expression for $v = v_t$.



(*a*) Apply $\sum F_y = ma_y$ to the parachutist immediately after the chute opens:

$$10bv^2 - mg = ma_{\substack{\text{chute}\\\text{open}}}$$

Solving for $a_{\substack{\text{chute}\\\text{open}}}$ yields:

$$a_{\substack{\text{chute}\\\text{open}}} = 10\frac{b}{m}v^2 - g \qquad (1)$$

Before the chute opened:

$$bv^2 - mg = ma_y$$

Under terminal speed conditions, $a_y = 0$ and:

$$bv_t^2 - mg = 0 \Rightarrow \frac{b}{m} = \frac{g}{v_t^2}$$

Substitute for b/m in equation (1) to obtain:

$$a_{\substack{\text{chute}\\\text{open}}} = 10\left(g\frac{1}{v_t^2}\right)v^2 - g$$

$$= \left[10\left(\frac{1}{v_t^2}\right)v^2 - 1\right]g$$

Evaluating $a_{\substack{\text{chute}\\\text{open}}}$ for $v = v_t$ yields:

$$a_{\substack{\text{chute}\\\text{open}}} = \left[10\left(\frac{1}{v_t^2}\right)v_t^2 - 1\right]g = \boxed{9g}$$

(*b*) Because this acceleration exceeds the safe acceleration by 4*g*, this is not a safe practice.

135 • Find the location of the center of mass of the Earth–moon system relative to the center of Earth. Is it inside or outside the surface of Earth?

Picture the Problem We can use the definition of the location of the center of mass of a system of particles to find the location of the center of mass of the Earth-moon system. The following pictorial representation is, of course, not shown to scale.

The center of mass of the Earth-moon system is given by:

$$x_{cm} = \frac{m_E x_{cm,E} + m_m x_{cm,m}}{m_E + m_m}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{cm} = \frac{(5.98\times10^{24}\text{ kg})(0) + (7.36\times10^{22}\text{ kg})(3.84\times10^{8}\text{ m})}{5.98\times10^{24}\text{ kg} + 7.36\times10^{22}\text{ kg}} = \boxed{4.67\times10^{6}\text{ m}}$$

Because the radius of Earth is 6.37×10^6 m, the center of mass of the Earth-moon system is inside Earth.

136 •• A circular plate of radius R has a circular hole of radius $R/2$ cut out of it (Figure 5-86). Find the center of mass of the plate after the hole has been cut. *Hint: The plate can be modeled as two disks superimposed, with the hole modeled as a disk of negative mass.*

Picture the Problem By symmetry, $x_{cm} = 0$. Let σ be the mass per unit area of the disk. The mass of the modified disk is the difference between the mass of the whole disk and the mass that has been removed.

Start with the definition of y_{cm}:

$$y_{cm} = \frac{\sum_i m_i y_i}{M - m_{hole}} = \frac{m_{disk} y_{disk} - m_{hole} y_{hole}}{M - m_{hole}}$$

Express the mass of the complete disk:

$$M = \sigma A = \sigma\pi r^2$$

Express the mass of the material removed:

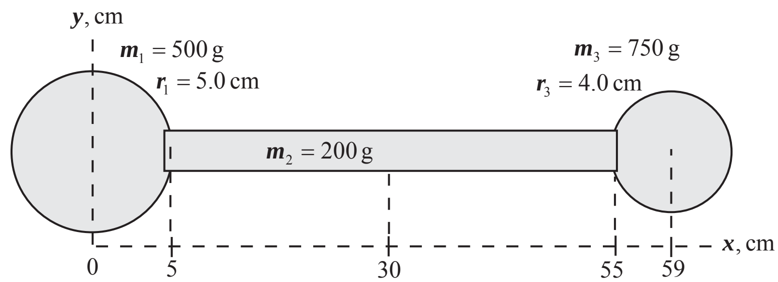
$$m_{hole} = \sigma\pi\left(\frac{r}{2}\right)^2 = \tfrac{1}{4}\sigma\pi r^2 = \tfrac{1}{4}M$$

Substitute and simplify to obtain:

$$y_{cm} = \frac{M(0) - \left(\frac{1}{4}M\right)\left(-\frac{1}{2}r\right)}{M - \frac{1}{4}M} = \boxed{\tfrac{1}{6}r}$$

137 •• An unbalanced baton consists of a 50-cm-long uniform rod of mass 200 g. At one end there is a 10-cm-diameter uniform solid sphere of mass 500 g, and at the other end there is a 8.0-cm-diameter uniform solid sphere of mass 750 g. (The center-to-center distance between the spheres is 59 cm.) (*a*) Where, relative to the center of the light sphere, is the center of mass of this baton? (*b*) If this baton is tossed straight up (but spinning) so that its initial center of mass speed is 10.0 m/s, what is the velocity of the center of mass 1.5 s later? (*c*) What is the net external force on the baton while in the air? (*d*) What is the baton's acceleration 1.5 s following its release?

Picture the Problem The pictorial representation summarizes the information concerning the unbalanced baton and shows a convenient choice for a coordinate system.



(*a*) The *x* coordinate of the center of mass of the unbalanced baton is given by:

$$x_{cm} = \frac{m_1 x_{cm,1} + m_2 x_{cm,2} + m_3 x_{cm,3}}{m_1 + m_2 + m_3}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{cm} = \frac{(500\text{ g})(0) + (200\text{ g})(30\text{ cm}) + (750\text{ g})(59\text{ cm})}{500\text{ g} + 200\text{ g} + 750\text{ g}} = \boxed{35\text{ cm}}$$

(*b*) Because the center of mass of the baton acts like a point particle, use a constant-acceleration equation to express is velocity as a function of time:

$$v(t) = v_{0,y} + a_y t$$

or, because $a_y = -g$,

$$v(t) = v_{0,y} - gt$$

Substitute numerical values and evaluate $v(1.5\text{ s})$:

$$\begin{aligned} v(1.5\text{ s}) &= 10.0\text{ m/s} - (9.81\text{ m/s}^2)(1.5\text{ s}) \\ &= -4.7\text{ m/s} \\ &= \boxed{4.7\text{ m/s downward}} \end{aligned}$$

(*c*) The net external force acting on the baton is the gravitational force (weight) exerted on it by Earth:

$$F_{net} = F_g = (m_1 + m_2 + m_3)g$$

Substitute numerical values and evaluate F_{net}:

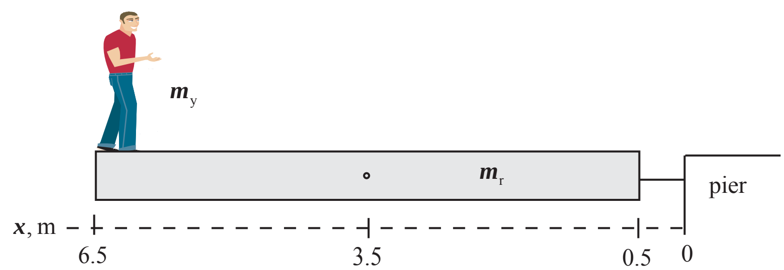
$$F_{net} = (500\text{ g} + 200\text{ g} + 750\text{ g})(9.81\text{ m/s}^2) = \boxed{14.2\text{ kN}}$$

(*d*) Again, because the center of mass acts like a point particle, its acceleration is that of a point particle in flight near the surface of Earth:

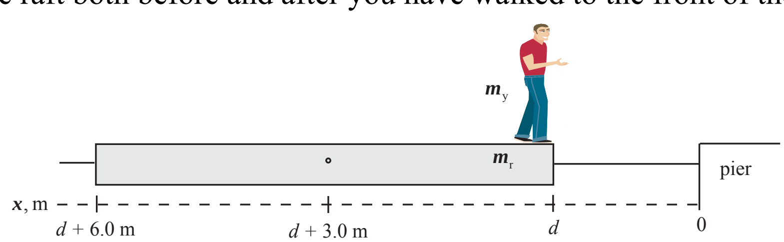
$$a_{cm} = g = \boxed{-9.81\text{ m/s}^2}$$

138 •• You are standing at the very rear of a 6.0-m-long, 120-kg raft that is at rest in a lake with its prow only 0.50 m from the end of the pier (Figure 5-87). Your mass is 60 kg. Neglect frictional forces between the raft and the water. (*a*) How far from the end of the pier is the center of mass of the you-raft system? (*b*) You walk to the front of the raft and then stop. How far from the end of the pier is the center of mass now? (*c*) When you are at the front of the raft, how far are you from the end of the pier?

Picture the Problem Let the origin be at the edge of the pier and the +*x* direction be to the right as shown in the pictorial representation immediately below.



In the following pictorial representation, *d* is the distance of the end of the raft from the pier after you have walked to its front. The raft moves to the left as you move to the right; with the center of mass of the you-raft system remaining fixed (because $F_{ext,net} = 0$). The diagram shows the initial ($x_{y,i}$) and final ($x_{y,f}$) positions of yourself as well as the initial ($x_{r\_cm,i}$) and final ($x_{r\_cm,f}$) positions of the center of mass of the raft both before and after you have walked to the front of the raft.



(*a*) x_{cm} before you walk to the front of the raft is given by:

$$x_{cm} = \frac{m_y x_{y,i} + m_r x_{r\_cm,i}}{m_y + m_r}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{cm}=\frac{(60\ \text{kg})(6.5\ \text{m})+(120\ \text{kg})(3.5\ \text{m})}{60\ \text{kg}+120\ \text{kg}}=\boxed{4.5\ \text{m}}$$

(*b*) Because $F_{ext,net}=0$, the center of mass remains fixed:

$$x'_{cm}=x_{cm}=\boxed{4.5\ \text{m}}$$

(*c*) Call the distance of the raft from the pier after you have walked to the front of the raft d and express the new location x'_{cm} of the center of mass of the system:

$$x'_{cm}=\frac{m_y x_{y,f}+m_r x_{r\_cm,f}}{m_y+m_r}=\frac{m_y d+m_r(d+3.0\ \text{m})}{m_y+m_r}=4.5\ \text{m}$$

Solving for d yields:

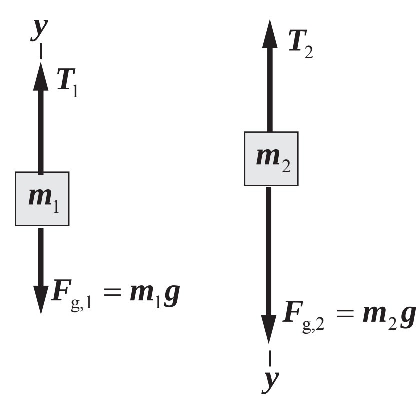
$$d=\frac{(4.5\ \text{m})m_y+(1.5\ \text{m})m_r}{m_y+m_r}$$

Substitute numerical values and evaluate x_{cm}:

$$d=\frac{(4.5\ \text{m})(60\ \text{kg})+(1.5\ \text{m})(120\ \text{kg})}{60\ \text{kg}+120\ \text{kg}}=\boxed{2.5\ \text{m}}$$

139 •• An Atwood's machine that has a frictionless massless pulley and massless strings has a 2.00-kg object hanging from one side and 4.00-kg object hanging from the other side. (*a*) What is the speed of each object 1.50 s after they are released from rest? (*b*) At that time, what is the velocity of the center of mass of the two objects? (*c*) At that time, what is the acceleration of the center of mass of the two objects?

Picture the Problem The forces acting on the 2.00-kg (m_1) and 4.00-kg (m_2) objects are shown in the free-body diagrams to the right. Note that the two objects have the same acceleration and common speeds. We can use constant-acceleration equations and Newton's second law in the analysis of the motion of these objects.



(*a*) Use a constant-acceleration equation to relate the speed of the objects to their common acceleration:

$$v(t) = v_{0y} + a_y t$$

or, because $v_{0y} = 0$,

$$v(t) = a_y t \qquad (1)$$

Apply $\sum F_y = ma_y$ to the object whose mass is m_1:

$$T_1 - m_1 g = m_1 a_y$$

Apply $\sum F_y = ma_y$ to the object whose mass is m_2:

$$m_2 g - T_2 = m_2 a_y$$

Because $T_1 = T_2$, adding these equations yields:

$$m_2 g - m_1 g = m_2 a_y + m_1 a_y$$

Solve for a_y to obtain:

$$a_y = \left(\frac{m_2 - m_1}{m_2 + m_1}\right) g \qquad (2)$$

Substituting for a_y in equation (1) yields:

$$v(t) = \left(\frac{m_2 - m_1}{m_2 + m_1}\right) g\,t$$

Substitute numerical values and evaluate $v(1.50\ \text{s})$:

$$v(1.50\ \text{s}) = \left(\frac{4.00\ \text{kg} - 2.00\ \text{kg}}{4.00\ \text{kg} + 2.00\ \text{kg}}\right)(9.81\ \text{m/s}^2)(1.50\ \text{s}) = 4.905\ \text{m/s} = \boxed{4.91\ \text{m/s}}$$

(*b*) The velocity of the center of mass is given by:

$$\vec{\boldsymbol{v}}_{\text{cm}} = \frac{m_1 \vec{\boldsymbol{v}}_1 + m_2 \vec{\boldsymbol{v}}_2}{m_1 + m_2}$$

Substitute numerical values and evaluate $v_{\text{cm}}(1.50\ \text{s})$:

$$v_{\text{cm}}(1.50\ \text{s}) = \frac{(2.00\ \text{kg})(4.905\ \text{m/s})\hat{j} + (4.00\ \text{kg})(-4.905\ \text{m/s})\hat{j}}{2.00\ \text{kg} + 4.00\ \text{kg}} = (-1.64\ \text{m/s})\hat{j}$$

The velocity of the center of mass is $\boxed{\text{1.64 m/s downward.}}$

(*c*) The acceleration of the center of mass is given by:

$$\vec{\boldsymbol{a}}_{\text{cm}} = \frac{m_1 \vec{\boldsymbol{a}}_1 + m_2 \vec{\boldsymbol{a}}_2}{m_1 + m_2}$$

Substituting for a_y from equation (2) and simplifying yields:

$$\vec{\boldsymbol{a}}_{\text{cm}} = \frac{m_1\left(\dfrac{m_2 - m_1}{m_2 + m_1}\right)g\,\hat{\boldsymbol{j}} + m_2\left(-\dfrac{m_2 - m_1}{m_2 + m_1}\right)g\,\hat{\boldsymbol{j}}}{m_1 + m_2} = -\left(\frac{m_2 - m_1}{m_2 + m_1}\right)^2 g\,\hat{\boldsymbol{j}}$$

Substitute numerical values and evaluate a_{cm}:

$$\vec{\boldsymbol{a}}_{\text{cm}} = -\left(\frac{4.00\text{ kg} - 2.00\text{ kg}}{4.00\text{ kg} + 2.00\text{ kg}}\right)^2\left(9.81\text{ m/s}^2\right)\hat{\boldsymbol{j}} = \left(-1.09\text{ m/s}^2\right)\hat{\boldsymbol{j}}$$

The acceleration of the center of mass is $\boxed{1.09\text{ m/s}^2\text{ downward.}}$

Chapter 6
Work and Kinetic Energy

Conceptual Problems

1 • True or false: (*a*) If the net or total work done on a particle was not zero, then its speed must have changed. (*b*) If the net or total work done on a particle was not zero, then its velocity must have changed. (*c*) If the net or total work done on a particle was not zero, then its direction of motion could not have changed. (*d*) No work is done by the forces acting on a particle if it remains at rest. (*e*) A force that is always perpendicular to the velocity of a particle never does work on the particle.

Determine the Concept A force does work on an object when its point of application moves through some distance and there is a component of the force along the line of motion.

(*a*) True. The total work done on a particle is equal to the change in its kinetic energy (the work-kinetic energy theorem).

(*b*) True. The total work done on the particle changes the kinetic energy of the particle, which means that its velocity must change.

(*c*) False. If the total work done on the particle is negative, it could be decreasing the particle's speed and, eventually, reversing its direction of motion.

(*d*) True. The object could be at rest in one reference frame and moving in another. If we consider only the frame in which the object is at rest, then, because it must undergo a displacement in order for work to be done on it, we would conclude that the statement is true.

(*e*) True. A force that is always perpendicular to the velocity of a particle changes the direction the particle is moving but does no work on the particle.

2 • You push a heavy box in a straight line along the top of a rough horizontal table. The box starts at rest and ends at rest. Describe the work done on it (including sign) by each force acting on it and the net work done on it.

Determine the Concept The normal and gravitational forces do zero work because they act at right angles to the box's direction of motion. You do positive work on the box and friction does negative work. Overall the net work is zero because its kinetic energy doesn't change (zero to zero).

3 • You are riding on a Ferris wheel that is rotating at constant speed. True or false: During any fraction of a revolution: (*a*) None of the forces acting on you does work on you. (*b*) The total work done by all forces acting on you is zero. (*c*) There is zero net force on you. (*d*) You are accelerating.

(*a*) False. Both the force exerted by the surface on which you are sitting and the gravitational force acting on you do work on you.

(*b*) False. Because you are rotating at constant speed, your kinetic energy does not change. However, since your height is continuously changing, your potential energy also changes continuously.

(*c*) False. Because you are continuously changing direction, and therefore accelerating, there is a net force acting on you that does work on you.

(*d*) True. Because the direction you are moving is continually changing, your velocity is continually changing and, hence, you are experiencing acceleration.

4 • By what factor does the kinetic energy of a particle change if its speed is doubled but its mass is cut in half?

Determine the Concept The kinetic energy of a particle is proportional to the square of its speed. Because $K = \frac{1}{2}mv^2$, replacing v by $2v$ and m by $\frac{1}{2}m$ yields

$$K' = \tfrac{1}{2}\left(\tfrac{1}{2}m\right)(2v)^2 = 2\left(\tfrac{1}{2}mv^2\right) = 2K\,.$$

Thus doubling the speed of a particle and halving its mass doubles its kinetic energy.

5 • Give an example of a particle that has constant kinetic energy but is accelerating. Can a non-accelerating particle have a changing kinetic energy? If so, give an example.

Determine the Concept A particle moving along a circular path at constant speed has constant kinetic energy but is accelerating (because its velocity is continually changing). No, because if the particle is not accelerating, the net force acting on it must be zero and, consequently, no work is done on it and its kinetic energy must be constant.

6 • A particle initially has kinetic energy *K*. Later it is found to be moving in the opposite direction with three times its initial speed. What is the kinetic energy now? (*a*) *K*, (*b*) 3*K*, (*c*) 23*K*, (*d*) 9*K*, (*e*) –9*K*

Determine the Concept The kinetic energy of a particle is proportional to the square of its speed and is always positive. Because $K = \frac{1}{2}mv^2$, replacing v by $3v$

yields $K' = \frac{1}{2}m(3v)^2 = 9\left(\frac{1}{2}mv^2\right) = 9K$. Hence tripling the speed of a particle increases its kinetic energy by a factor of 9 and $\boxed{(d)}$ is correct.

7 • **[SSM]** How does the work required to stretch a spring 2.0 cm from its unstressed length compare with the work required to stretch it 1.0 cm from its unstressed length?

Determine the Concept The work required to stretch or compress a spring a distance x is given by $W = \frac{1}{2}kx^2$ where k is the spring's stiffness constant. Because $W \propto x^2$, doubling the distance the spring is stretched will require four times as much work.

8 • A spring is first stretched 2.0 cm from its unstressed length. It is then stretched an additional 2.0 cm. How does the work required for the second stretch compare to the work required for the first stretch (give a ratio of second to first)?

Picture the Problem The work required to stretch or compress a spring a distance x is given by $W = \frac{1}{2}kx^2$ where k is the spring's stiffness constant.

Letting x_1 represent the length of the first stretch, express the work (the energy stored in the spring after the stretch) done on the spring during the first stretch:

$$W_1 = \tfrac{1}{2}kx_1^2$$

The work done in stretching the spring from x_1 to x_2 is given by:

$$\begin{aligned} W_2 &= \tfrac{1}{2}kx_2^2 - \tfrac{1}{2}kx_1^2 = \tfrac{1}{2}k(2x_1)^2 - \tfrac{1}{2}kx_1^2 \\ &= 4\left(\tfrac{1}{2}kx_1^2\right) - \tfrac{1}{2}kx_1^2 = 3\left(\tfrac{1}{2}kx_1^2\right) \end{aligned}$$

Express the ratio of W_2 to W_1 to obtain:

$$\frac{W_2}{W_1} = \frac{3\left(\frac{1}{2}kx_1^2\right)}{\frac{1}{2}kx_1^2} = \boxed{3}$$

9 • The dimension of power is (*a*) M·L^2·T^2, (*b*) M·L^2/T, (*c*) M·L^2/T^2, (*d*) M·L^2/T^3.

Determine the Concept We can use the definition of power as the scalar product of force and velocity to express the dimension of power.

Power is defined to be the product of force and velocity:

$$P = \vec{F} \cdot \vec{v}$$

Express the dimension of force:

$$\frac{\mathrm{M \cdot L}}{\mathrm{T}^2}$$

Express the dimension of velocity: $\dfrac{\text{L}}{\text{T}}$

Express the dimension of power in terms of those of force and velocity: $\dfrac{\text{M}\cdot\text{L}}{\text{T}^2}\cdot\dfrac{\text{L}}{\text{T}}=\dfrac{\text{M}\cdot\text{L}^2}{\text{T}^3}\Rightarrow\boxed{(d)}$ is correct.

10 • Show that the SI units of the force constant of a spring can be written as kg/s^2 .

Picture the Problem We can use the relationship $F = kx$ to establish the SI units of *k*.

Solve $F = kx$ for *k* to obtain: $k=\dfrac{F}{x}$

Substitute the units of *F*/*x* and simplify to obtain: $\dfrac{\text{N}}{\text{m}}=\dfrac{\dfrac{\text{kg}\cdot\text{m}}{\text{s}^2}}{\text{m}}=\boxed{\text{kg}/\text{s}^2}$

11 • True or false: (*a*) The gravitational force cannot do work on an object, because it is not a contact force. (*b*) Static friction can never do work on an object. (*c*) As a negatively charged electron in an atom is pulled from a positively charged nucleus, the force between the electron and the nucleus does work that has a positive value. (*d*) If a particle is moving along a circular path, the total work being done on it is necessarily zero.

Comment: DAVID: The answer to part (d) is now FALSE.

(*a*) False. The definition of work is not limited to displacements caused by contact forces. Consider the work done by the gravitational force on an object in freefall.

(*b*) False. The force that Earth exerts on your foot as you walk (or run) is a static friction force. Another example is the force that Earth exerts on the tire mounted on a drive wheel of an automobile.

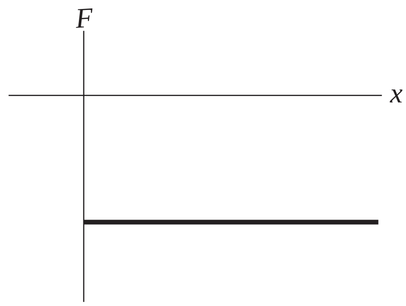
(*c*) False. The direction of the electric force on the electron during its removal from the atom is opposite that of the displacement of the electron.

(*d*) False. If the particle is accelerating, there must be a net force acting on it and, hence, work is done on it.

12 •• A hockey puck has an initial velocity in the +*x* direction on a horizontal sheet of ice. Qualitatively sketch the force-versus-position graph for the (constant) horizontal force that would need to act on the puck to bring it to rest. Assume that the puck is located at *x* = 0 when the force begins to act. Show

that the sign of the area under the curve agrees with the sign of the change in the puck's kinetic energy and interpret this in terms of the work–kinetic–energy theorem.

Determine the Concept The graph of the force F acting on the puck as a function of its position x is shown to the right. Note that, because the force is negative, the area bounded by it and the x axis is negative and, hence, the net work done by the force is negative. In accordance with the work-kinetic energy theorem, the change in kinetic energy is negative and the puck loses all of its initial kinetic energy.



13 •• [SSM] True or false: (*a*) The scalar product cannot have units. (*b*) If the scalar product of two nonzero vectors is zero, then they are parallel. (*c*) If the scalar product of two nonzero vectors is equal to the product of their magnitudes, then the two vectors are parallel. (*d*) As an object slides up an incline, the sign of the scalar product of the force of gravity on it and its displacement is negative.

(*a*) False. Work is the scalar product of force and displacement.

(*b*) False. Because $\vec{A}\cdot\vec{B} = AB\cos\theta,$ where θ is the angle between $\vec{A}$ and $\vec{B},$ if the scalar product of the vectors is zero, then θ must be 90° (or some odd multiple of 90°) and the vectors are perpendicular.

(*c*) True. Because $\vec{A}\cdot\vec{B} = AB\cos\theta,$ where θ is the angle between $\vec{A}$ and $\vec{B},$ if the scalar product of the vectors is equal to the product of their magnitudes, then θ must be 0° and the vectors are parallel.

(*d*) True. Because the angle between the gravitational force and the displacement of the object is greater than 90°, its cosine is negative and, hence, the scalar product is negative.

14 •• (*a*) Must the scalar product of two perpendicular unit vectors always be zero? If not, give an example. (*b*) An object has a velocity $\vec{v}$ at some instant. Interpret $\sqrt{\vec{v}\cdot\vec{v}}$ physically. (*c*) A ball rolls off a horizontal table. What is the scalar product between its velocity and its acceleration the instant after it leaves the table? Explain. (*d*) In Part (*c*), what is the sign of the scalar product of its velocity and acceleration the instant before it impacts the floor?

Determine the Concept
(a) Yes. Any unit vectors that are not perpendicular to each other (as are $\hat{\boldsymbol{i}}$, $\hat{\boldsymbol{j}}$, and $\hat{\boldsymbol{k}}$) will have a scalar product different from zero.

(b) $\sqrt{\vec{v}\cdot\vec{v}}=\sqrt{v^2\cos 0°}=v$ is the object's speed.

(c) Zero, because at the instant the ball leaves the horizontal table, $\vec{v}$ and $\vec{a}(=\vec{g})$ are perpendicular.

(d) Positive, because the final velocity of the ball has a downward component in the direction of the acceleration.

15 •• You lift a package vertically upward a distance L in time Δt. You then lift a second package that has twice the mass of the first package vertically upward the same distance while providing the same power as required for the first package. How much time does lifting the second package take (answer in terms of Δt)?

Picture the Problem Power is the rate at which work is done.

Express the power you exert in lifting the package one meter in Δt seconds:

$$P_1=\frac{W_1}{\Delta t_1}=\frac{W_1}{\Delta t}$$

Express the power you develop in lifting a package of twice the mass one meter in t seconds:

$$P_2=\frac{W_2}{\Delta t_2}=\frac{2W_1}{\Delta t_2}$$

Because you exert the same power in lifting both packages:

$$\frac{W_1}{\Delta t}=\frac{2W_1}{\Delta t_2}\Rightarrow \Delta t_2=\boxed{2\Delta t}$$

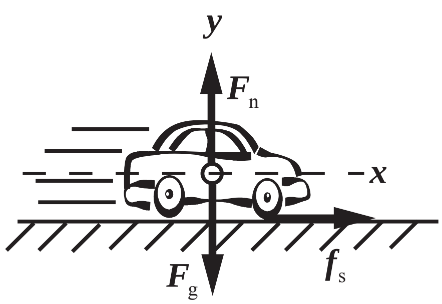
16 •• There are lasers that output more than 1.0 GW of power. A typical large modern electric generation plant typically produces 1.0 GW of electrical power. Does this mean the laser outputs a huge amount of energy? Explain. *Hint: These high-power lasers are pulsed on and off, so they are not outputting power for very long time intervals.*

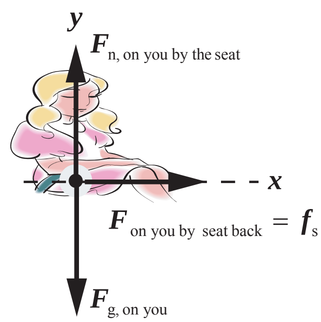
Determine the Concept No, the laser power may only last for a short time interval.

17 •• **[SSM]** You are driving a car that accelerates from rest on a level road without spinning its wheels. Use the center-of-mass work–translational-kinetic-energy relation and free-body diagrams to clearly explain which force (or

forces) is (are) directly responsible for the gain in translational kinetic energy of both you and the car. *Hint: The relation refers to external forces only, so the car's engine is not the answer. Pick your ″system″ correctly for each case.*

Determine the Concept The car shown in the free-body diagram is accelerating in the $+x$ direction, as are you (shown to the right). The only external force (neglecting air resistance) that does center-of-mass work on the car is the static friction force $\vec{f}_s$ exerted by the road on the tires. The positive center-of-mass work this friction force does is translated into a gain of kinetic energy.





Estimation and Approximation

18 •• [SSM] (*a*) Estimate the work done on you by gravity as you take an elevator from the ground floor to the top of the Empire State Building, a building 102 stories high. (*b*) Estimate the amount of work the normal force of the floor did on you. *Hint: The answer is not zero.* (*c*) Estimate the average power of the force of gravity.

Picture the Problem According to the work-kinetic energy theorem, the work done on you by gravity and the normal force exerted by the floor equals your change in kinetic energy.

(*a*) The definition of work is:

$$W = \int_{s_1}^{s_2} \vec{F} \cdot d\vec{s} \qquad (1)$$

Assuming a coordinate system in which the upward direction is the $+y$ direction, $\vec{F}$ and $d\vec{s}$ are given by:

$$\vec{F} = -mg\,\hat{j}$$

and

$$d\vec{s} = dy\,\hat{j}$$

Substitute for $\vec{F}$ and $d\vec{s}$ in equation (1) to obtain:

$$W_{\text{by gravity}} = \int_0^h -mg\,\hat{j} \cdot dy\,\hat{j} = -mg\int_0^h dy$$

where h is the height of the Empire State building.

Evaluating this integral yields:

$$W_{\text{by gravity}} = -mgh$$

Assume that your mass is 70 kg and that the height of the Empire State building is 300 m (102 floors). Then:

$$W_{\text{by gravity}} = -(70\text{ kg})(9.81\text{ m/s}^2)(300\text{ m}) = -2.060\times10^5\text{ J} \approx \boxed{-2.1\times10^5\text{ J}}$$

(*b*) Apply the work-kinetic energy theorem to obtain:

$$W_{\text{by gravity}} + W_{\text{by floor}} = \Delta K$$

or, because your change in kinetic energy is zero,

$$W_{\text{by gravity}} + W_{\text{by floor}} = 0$$

Solve for $W_{\text{by floor}}$ to obtain:

$$W_{\text{by floor}} = -W_{\text{by gravity}}$$

Substituting for $W_{\text{by gravity}}$ yields:

$$W_{\text{by floor}} \approx -(-2.060\times10^5\text{ J}) = \boxed{2.1\times10^5\text{ J}}$$

(*c*) If it takes 1 min to ride the elevator to the top floor, then the average power of the force of gravity is:

$$P_{\text{av}} = \frac{\Delta W}{\Delta t} = \frac{2.060\times10^5\text{ J}}{60\text{ s}} = \boxed{3.4\text{ kW}}$$

Remarks: Some books say the normal force cannot do work. Having solved this problem, what do you think about that statement?

19 •• The nearest stars, apart from the Sun, are light-years away from Earth. If we are to investigate these stars, our space ships will have to travel at an appreciable fraction of the speed of light. (*a*) You are in charge of estimating the energy required to accelerate a 10,000-kg capsule from rest to 10 percent of the speed of light in one year. What is the minimum amount of energy that is required? Note that at velocities approaching the speed of light, the kinetic energy formula $\frac{1}{2}mv^2$ is not correct. However, it gives a value that is within 1% of the correct value for speeds up to 10% of the speed of light. (*b*) Compare your estimate to the amount of energy that the United States uses in a year (about 5×10^{20} J). (*c*) Estimate the minimum average power required of the propulsion system.

Comment: DAVID: Wording changes will likely impact the solution.

Picture the Problem We can find the kinetic energy *K* of the spacecraft from its definition and compare its energy to the annual consumption in the United States by examining the ratio *K*/*E*. Finally, we can use the definition of power to find the average power required of the engines.

(*a*) The work required by the propulsion system equals the kinetic energy of the spacecraft:

$$W = \Delta K = K_f = \tfrac{1}{2}m(0.10c)^2$$

Substitute numerical values and evaluate *W*:

$$W = \tfrac{1}{2}(10^4\text{ kg})[(0.10)(2.998\times10^8\text{ m/s})]^2 = \boxed{4.5\times10^{18}\text{ J}}$$

(*b*) Express this amount of energy as a percentage of the annual consumption in the United States:

$$\frac{K}{E} \approx \frac{4.5\times10^{18}\text{ J}}{5\times10^{20}\text{ J}} \approx \boxed{1\%}$$

(*c*) The average power is the rate at which work is done (or energy is delivered):

$$P_{av} = \frac{\Delta W}{\Delta t} = \frac{\Delta K}{\Delta t}$$

Substitute numerical values and evaluate $P_{av,\,min}$:

$$P_{av,\,min} = \frac{4.5\times10^{18}\text{ J}}{1\text{ y}\times\dfrac{3.156\times10^7\text{ s}}{\text{y}}} = \boxed{1.4\times10^{11}\text{ W}}$$

20 •• The mass of the Space Shuttle orbiter is about 8×10^4 kg and the period of its orbit is 90 min. Estimate the kinetic energy of the orbiter and the work done on it by gravity between launch and orbit. (Although the force of gravity decreases with altitude, this affect is small in low-Earth orbit. Use this fact to make the necessary approximation; you do not need to do an integral.) The orbits are about 250 miles above the surface of Earth.

Picture the Problem We can find the orbital speed of the Shuttle from the radius of its orbit and its period and its kinetic energy from $K = \tfrac{1}{2}mv^2$. We'll ignore the variation in the acceleration due to gravity to estimate the change in the potential energy of the orbiter between its value at the surface of Earth and its orbital value.

Apply the work-kinetic energy theorem to the orbiter to obtain:

$$W_{by\ gravity} = \Delta K = K_{orbital} - K_{launch}$$

or, because $K_{launch} = 0$,

$$W_{by\ gravity} = K_{orbital} \quad (1)$$

The kinetic energy of the orbiter in orbit is given by:

$$K_{orbital} = \tfrac{1}{2}mv^2 \quad (2)$$

Relate the orbital speed of the orbiter to its radius *r* and period *T*:

$$v = \frac{2\pi r}{T}$$

Substitute for v in equation (2) and simplify to obtain:

$$K_{\text{orbital}} = \tfrac{1}{2}m\left(\frac{2\pi r}{T}\right)^2 = \frac{2\pi^2 mr^2}{T^2}$$

Substitute numerical values and evaluate K_{orbital}:

$$K_{\text{orbital}} = \frac{2\pi^2(8\times10^4\text{ kg})[(250\text{ mi}+3960\text{ mi})(1.609\text{ km/mi})]^2}{[(90\text{ min})(60\text{ s/min})]^2} \approx \boxed{2\text{ TJ}}$$

Substitute for K_{orbital} in equation (1) to obtain:

$$W_{\text{by gravity}} \approx \boxed{2\text{ TJ}}$$

21 • Ten inches of snow have fallen during the night, and you must shovel out your 50-ft-long driveway (Figure 6-29). Estimate how much work you do on the snow by completing this task. Make a plausible guess of any value(s) needed (the width of the driveway, for example), and state the basis for each guess.

Picture the Problem Let's assume that the width of the driveway is 18 ft. We'll also assume that you lift each shovel full of snow to a height of 1 m, carry it to the edge of the driveway, and drop it. We'll ignore the fact that you must slightly accelerate each shovel full as you pick it up and as you carry it to the edge of the driveway. While the density of snow depends on the extent to which it has been compacted, one liter of freshly fallen snow is approximately equivalent to 100 mL of water.

Express the work you do in lifting the snow a distance h:

$$W = \Delta U = mgh = \rho_{\text{snow}}V_{\text{snow}}gh$$

where ρ is the density of the snow.

Using its definition, express the densities of water and snow:

$$\rho_{\text{snow}} = \frac{m_{\text{snow}}}{V_{\text{snow}}} \text{ and } \rho_{\text{water}} = \frac{m_{\text{water}}}{V_{\text{water}}}$$

Divide the first of these equations by the second to obtain:

$$\frac{\rho_{\text{snow}}}{\rho_{\text{water}}} = \frac{V_{\text{water}}}{V_{\text{snow}}} \Rightarrow \rho_{\text{snow}} = \rho_{\text{water}}\frac{V_{\text{water}}}{V_{\text{snow}}}$$

Substitute numerical values and evaluate ρ_{snow}:

$$\rho_{\text{snow}} = (10^3\text{ kg/m}^3)\frac{100\text{ mL}}{\text{L}} = 100\text{ kg/m}^3$$

Calculate the volume of snow covering the driveway:

$$\begin{aligned} V_{\text{snow}} &= (50\text{ ft})(18\text{ ft})\left(\frac{10}{12}\text{ ft}\right) \\ &= 750\text{ ft}^3 \times \frac{28.32\text{ L}}{\text{ft}^3} \times \frac{10^{-3}\text{ m}^3}{\text{L}} \\ &= 21.2\text{ m}^3 \end{aligned}$$

Substitute numerical values in the expression for W to obtain an estimate (a lower bound) for the work you would do on the snow in removing it:

$$W = (100\,\text{kg/m}^3)(21.2\,\text{m}^3)(9.81\,\text{m/s}^2)(1\,\text{m}) = \boxed{21\,\text{kJ}}$$

Remarks: Note that the work done on the snow is zero when it is carried to the end of the driveway because F_{applied} is perpendicular to the displacement.

Work, Kinetic Energy and Applications

22 • A 15-g piece of space junk has a speed of 1.2 km/s. (*a*) What is its kinetic energy? (*b*) What is its kinetic energy if its speed is halved? (*c*) What is its kinetic energy if its speed is doubled?

Comment: DAVID: Please purge "bullet" from your solution.

Picture the Problem We can use $\frac{1}{2}mv^2$ to find the kinetic energy of the piece of space junk.

(*a*) The kinetic energy of the piece of space junk is given by:

$$K = \tfrac{1}{2}mv^2$$

Substitute numerical values and evaluate K:

$$K = \tfrac{1}{2}(0.015\,\text{kg})(1.2\,\text{km/s})^2 = \boxed{11\,\text{kJ}}$$

(*b*) Because $K \propto v^2$:

$$K' = \tfrac{1}{4}K = \boxed{2.7\,\text{kJ}}$$

(*c*) Because $K \propto v^2$:

$$K' = 4K = \boxed{43\,\text{kJ}}$$

23 • Find the kinetic energy of (*a*) a 0.145-kg baseball moving with a speed of 45.0 m/s, and (*b*) a 60.0-kg jogger running at a steady pace of 9.00 min/mi.

Picture the Problem We can use $\frac{1}{2}mv^2$ to find the kinetic energy of the baseball and the jogger.

(*a*) Use the definition of K to find the kinetic energy of the baseball:

$$K_{\text{baseball}} = \tfrac{1}{2}(0.145\,\text{kg})(45.0\,\text{m/s})^2 = \boxed{147\,\text{J}}$$

(*b*) Convert the jogger's pace of 9.00 min/mi into a speed:

$$v = \left(\frac{1\,\text{mi}}{9.00\,\text{min}}\right)\left(\frac{1\,\text{min}}{60\,\text{s}}\right)\left(\frac{1609\,\text{m}}{1\,\text{mi}}\right) = 2.98\,\text{m/s}$$

Use the definition of K to find the jogger's kinetic energy:

$$K_{\text{jogger}} = \tfrac{1}{2}(60.0\,\text{kg})(2.98\,\text{m/s})^2 = \boxed{266\,\text{J}}$$

24 • A 6.0-kg box is raised a distance of 3.0 m from rest by a vertical applied force of 80 N. Find (*a*) the work done on the box by the applied force, (*b*) the work done on the box by gravity, and (*c*) the final kinetic energy of the box.

Picture the Problem The work done by the force acting on the box is the scalar product of the force producing the displacement and the displacement of the box. Because the weight of an object is the gravitational force acting on it and this force acts downward, the work done by gravity is negative. We can use the work-kinetic energy theorem to find the final kinetic energy of the box.

(*a*) Use the definition of work to obtain:

$$W_{\text{on the box}} = \vec{\boldsymbol{F}} \cdot \Delta\vec{\boldsymbol{y}} \qquad (1)$$

$\vec{\boldsymbol{F}}$ and $\Delta\vec{\boldsymbol{y}}$ are given by:

$$\vec{\boldsymbol{F}} = (80\,\text{N})\hat{\boldsymbol{j}}$$

and

$$\Delta\vec{\boldsymbol{y}} = (3.0\,\text{m})\hat{\boldsymbol{j}}$$

Substitute for $\vec{\boldsymbol{F}}$ and $\Delta\vec{\boldsymbol{y}}$ in equation (1) and evaluate $W_{\text{on the box}}$:

$$W_{\text{on the box}} = (80\,\text{N})\hat{\boldsymbol{j}} \cdot (3.0\,\text{m})\hat{\boldsymbol{j}} = \boxed{0.24\,\text{kJ}}$$

(*b*) Apply the definition of work again to obtain:

$$W_{\text{by gravity}} = \vec{\boldsymbol{F}}_{\text{g}} \cdot \Delta\vec{\boldsymbol{y}} \qquad (2)$$

$\vec{\boldsymbol{F}}$ and $\Delta\vec{\boldsymbol{y}}$ are given by:

$$\vec{\boldsymbol{F}}_{\text{g}} = -mg\hat{\boldsymbol{j}} = -(6.0\,\text{kg})(9.81\,\text{m/s}^2)\hat{\boldsymbol{j}} = (-58.9\,\text{N})\hat{\boldsymbol{j}}$$

and

$$\Delta\vec{\boldsymbol{y}} = (3.0\,\text{m})\hat{\boldsymbol{j}}$$

Substituting for $\vec{\boldsymbol{F}}$ and $\Delta\vec{\boldsymbol{y}}$ and simplifying yields:

$$W_{\text{by gravity}} = (-58.9\,\text{N})\hat{\boldsymbol{j}} \cdot (3.0\,\text{m})\hat{\boldsymbol{j}} = \boxed{-0.18\,\text{kJ}}$$

(*c*) According to the work-kinetic energy theorem:

$$\Delta K = W_{\text{on the box}} + W_{\text{by gravity}}$$

or, because $K_{\text{i}} = 0$,

$$K_{\text{f}} = W_{\text{on the box}} + W_{\text{by gravity}}$$

Substitute numerical values and evaluate K_f:

$$K_f = 0.24\ \text{kJ} - 0.18\ \text{kJ} = \boxed{0.06\ \text{kJ}}$$

25 • A constant 80-N force acts on a 5.0 kg box. The box initially is moving at 20 m/s in the direction of the force, and 3.0 s later the box is moving at 68 m/s. Determine both the work done by this force and the average power delivered by the force during the 3.0-s interval.

Comment: DAVID: The new wording give 2 sig figs to the time interval.

Comment: AU: OK to add for clarity?

Picture the Problem The constant force of 80 N is the net force acting on the box and the work it does is equal to the *change* in the kinetic energy of the box. The power of the force is the rate at which it does work on the box.

Using the work-kinetic energy theorem, relate the work done by the constant force to the *change* in the kinetic energy of the box:

$$W = K_f - K_i = \tfrac{1}{2}m\left(v_f^2 - v_i^2\right)$$

Substitute numerical values and evaluate W:

$$W = \tfrac{1}{2}(5.0\,\text{kg})\left[(68\,\text{m/s})^2 - (20\,\text{m/s})^2\right] = 10.6\,\text{kJ} = \boxed{11\,\text{kJ}}$$

The average power delivered by the force is given by:

$$P = \frac{\Delta W}{\Delta t}$$

Substitute numerical values and evaluate P:

$$P = \frac{10.6\ \text{kJ}}{3.0\ \text{s}} = \boxed{3.5\ \text{kW}}$$

26 •• You run a race with a friend. At first you each have the same kinetic energy, but she is running faster than you are. When you increase your speed by 25 percent, you are running at the same speed she is. If your mass is 85 kg, what is her mass?

Picture the Problem We can use the definition of kinetic energy to find the mass of your friend.

Using the definition of kinetic energy and letting ″1″ denote your mass and speed and ″2″ your girlfriend’s, express the equality of your kinetic energies:

$$\tfrac{1}{2}m_1v_1^2 = \tfrac{1}{2}m_2v_2^2 \Rightarrow m_2 = m_1\left(\frac{v_1}{v_2}\right)^2$$

Express the condition on your speed that enables you to run at the same speed as your girlfriend:

$$v_2 = 1.25v_1$$

Substitute for v_2 and simplify to obtain:

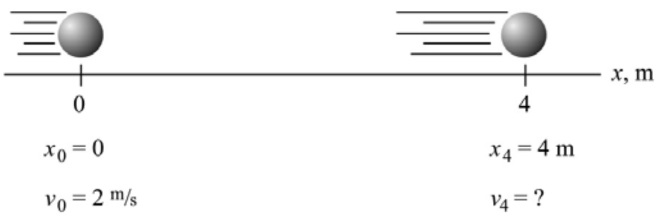
$$m_2 = m_1\left(\frac{v_1}{1.25v_1}\right)^2 = m_1\left(\frac{1}{1.25}\right)^2$$

Substitute the numerical value of m_1 and evaluate m_2:

$$m_2 = (85\,\text{kg})\left(\frac{1}{1.25}\right)^2 = \boxed{54\,\text{kg}}$$

27 •• [SSM] A 3.0-kg particle moving along the x axis has a velocity of +2.0 m/s as it passes through the origin. It is subjected to a single force, F_x, that varies with position, as shown in Figure 6-30. (*a*) What is the kinetic energy of the particle as it passes through the origin? (*b*) How much work is done by the force as the particle moves from x = 0.0 m to x = 4.0 m? (*c*) What is the speed of the particle when it is at x = 4.0 m?

Picture the Problem The pictorial representation shows the particle as it moves along the positive x axis. The particle's kinetic energy increases because work is done on it. We can calculate the work done on it from the graph of F_x vs. x and relate its kinetic energy when it is at x = 4.0 m to its kinetic energy when it was at the origin and the work done on it by using the work-kinetic energy theorem.



(*a*) Calculate the kinetic energy of the particle when it is at x = 0:

$$K_0 = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(3.0\,\text{kg})(2.0\,\text{m/s})^2 = \boxed{6.0\,\text{J}}$$

(*b*) Because the force and displacement are parallel, the work done is the area under the curve. Use the formula for the area of a triangle to calculate the area under the $F(x)$ graph:

$$W_{0\to 4} = \tfrac{1}{2}(\text{base})(\text{altitude}) = \tfrac{1}{2}(4.0\,\text{m})(6.0\,\text{N}) = \boxed{12\,\text{J}}$$

(*c*) Express the kinetic energy of the particle at $x = 4.0$ m in terms of its speed and mass:

$$K_{4\,\text{s}} = \tfrac{1}{2}mv_{4\,\text{s}}^2 \Rightarrow v_{4\,\text{s}} = \sqrt{\frac{2K_{4\,\text{s}}}{m}} \quad (1)$$

Using the work-kinetic energy theorem, relate the work done on the particle to its *change* in kinetic energy:

$$W_{0\to4.0\,\text{m}} = K_{4\,\text{s}} - K_0$$

Solve for the particle's kinetic energy at $x = 4.0$ m:

$$K_{4\,\text{s}} = K_0 + W_{0\to4}$$

Substitute numerical values and evaluate $K_{4\,\text{s}}$:

$$K_{4\,\text{s}} = 6.0\,\text{J} + 12\,\text{J} = 18\,\text{J}$$

Substitute numerical values in equation (1) and evaluate v_4:

$$v_4 = \sqrt{\frac{2(18\,\text{J})}{3.0\,\text{kg}}} = \boxed{3.5\,\text{m/s}}$$

28 •• A 3.0-kg object moving along the *x* axis has a velocity of 2.4 m/s as it passes through the origin. It is acted on by a single force, F_x, that varies with *x*, as shown in Figure 6-31. (*a*) Find the work done by the force from $x = 0.0$ m to $x = 2.0$ m. (*b*) What is the kinetic energy of the object at $x = 2.0$ m? (*c*) What is the speed of the object at $x = 2.0$ m? (*d*) What is the work done on the object from $x = 0.0$ to $x = 4.0$ m? (*e*) What is the speed of the object at $x = 4.0$ m?

Picture the Problem The work done on an object can be determined by finding the area bounded by its graph of F_x as a function of *x* and the *x* axis. We can find the kinetic energy and the speed of the particle at any point by using the work-kinetic energy theorem.

(*a*) Express *W*, the area under the curve, in terms of the area of one square, A_{square}, and the number of squares *n*:

$$W_{0\to2\,\text{m}} = nA_{\text{square}} \quad (1)$$

Determine the work equivalent of one square:

$$A_{\text{square}} = (0.5\,\text{N})(0.25\,\text{m}) = 0.125\,\text{J}$$

Estimate the number of squares under the curve between $x = 0$ and $x = 2.0$ m:

$$n \approx 22$$

Substitute for n and A_{square} in equation (1) and evaluate W:

$$W_{0\to 2\,\text{m}} = (22)(0.125\text{ J}) = 2.75\text{ J} = \boxed{2.8\text{ J}}$$

(b) Relate the kinetic energy of the object at $x = 2.0$ m, K_2, to its initial kinetic energy, K_0, and the work that was done on it between $x = 0$ and $x = 2.0$ m:

$$K_{2\,\text{m}} = K_0 + W_{0\to 2\,\text{m}}$$

Substitute numerical values and evaluate $K_{2\,\text{m}}$:

$$K_{2\,\text{m}} = \tfrac{1}{2}(3.0\text{ kg})(2.4\text{ m/s})^2 + 2.75\text{ J} = 11.4\text{ J} = \boxed{11\text{ J}}$$

(c) The speed of the object at $x = 2.0$ m is given by:

$$v_{2\,\text{m}} = \sqrt{\frac{2K_{2\,\text{m}}}{m}}$$

Substitute numerical values and evaluate $v_{2\,\text{m}}$:

$$v = \sqrt{\frac{2(11.4\text{ J})}{3.0\text{ kg}}} = \boxed{2.8\text{ m/s}}$$

(d) Estimate the number of squares under the curve between $x = 0$ and $x = 4.0$ m:

$$n \approx 26$$

Substitute numerical values and evaluate $W_{0\to 4\,\text{m}}$:

$$W_{0\to 4\,\text{m}} = 26(0.125\text{ J}) = 3.25\text{ J} = \boxed{3.3\text{ J}}$$

(e) Relate the kinetic energy of the object at $x = 4.0$ m, K_4, to its initial kinetic energy, K_0, and the work that was done on it between $x = 0$ and $x = 4.0$ m:

$$K_4 = K_0 + W_{0\to 4\,\text{m}}$$

Substitute numerical values and evaluate K_4:

$$K_4 = \tfrac{1}{2}(3.0\text{ kg})(2.4\text{ m/s})^2 + 3.25\text{ J} = 11.9\text{ J}$$

The speed of the object at $x = 4.0$ m is given by:

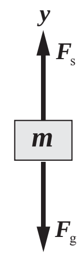
$$v_4 = \sqrt{\frac{2K_4}{m}}$$

Substitute numerical values and evaluate v_4:

$$v_4 = \sqrt{\frac{2(11.9\,\mathrm{J})}{3.0\,\mathrm{kg}}} = \boxed{2.8\,\mathrm{m/s}}$$

29 •• One end of a light spring (force constant k) is attached to the ceiling, the other end is attached to an object of mass m. The spring initially is vertical and unstressed. You then ″ease the object down″ to an equilibrium position a distance h below its initial position. Next, you repeat this experiment, but instead of easing the object down, you release it, with the result that it falls a distance H below the initial position before momentarily stopping. (a) Show that $h = mg/k$. (b) Use the work–kinetic-energy theorem to show that $H = 2h$. Try this experiment on your own.

Picture the Problem The free-body diagram shows the object at its equilibrium point. We can use Newton's second law under equilibrium conditions to show that $h = mg/k$ and the work-kinetic energy theorem to prove that $H = 2h$.



(a) Apply $\sum F_y = ma_y$ to the object in its equilibrium position:

$$F_s - F_g = 0$$

or, because $F_s = kh$ and $F_g = mg$,

$$kh - mg = 0 \Rightarrow h = \boxed{\frac{mg}{k}}$$

(b) Apply the work-kinetic energy theorem to the spring-object system to obtain:

$$W_{\text{net,ext}} = \Delta K$$

or, because the object begins and ends at rest,

$$W_{\text{net,ext}} = 0$$

The work done by the net external force is the sum of the work done by gravity and by the spring:

$$W_{\text{by gravity}} + W_{\text{by spring}} = 0$$

Because the force exerted on the object by the spring is upward and the displacement of the object is downward, $W_{\text{by spring}}$ is negative. Substituting for $W_{\text{by spring}}$ and $W_{\text{by gravity}}$ yields:

$$mgH - \tfrac{1}{2}kH^2 = 0 \Rightarrow H = \boxed{2h}$$

30 •• A force F_x acts on a particle that has a mass of 1.5 kg. The force is related to the position x of the particle by the formula $F_x = Cx^3$, where $C = 0.50$ if x is in meters and F_x is in newtons. (*a*) What are the SI units of C? (*b*) Find the work done by this force as the particle moves from x = 3.0 m to x = 1.5 m. (*c*) At x = 3.0 m, the force points opposite the direction of the particle's velocity (speed is 12.0 m/s). What is its speed at x =1.5 m? Can you tell its direction of motion at x =1.5 m using only the work-kinetic-energy theorem? Explain.

Comment: DAVID: Changes in numbers were made.

Picture the Problem The work done by this force as it displaces the particle is the area under the curve of F as a function of x. We can integrate F_x to find the work done on the particle and then use the work-kinetic energy theorem to find the particle's speed at x = 3.0 m.

(*a*) Solve the force equation for C to obtain:

$$C = \frac{F_x}{x^3} \text{ where } C \text{ has units of } \boxed{\frac{\text{N}}{\text{m}^3}}.$$

(*b*) Because F_x varies with position non-linearly, we need to express the work it does as an integral:

$$W_{\text{net, ext}} = \int \vec{\boldsymbol{F}}_x \cdot d\vec{\boldsymbol{x}} = \int -F_x dx$$

where the minus sign is a consequence of the fact that the direction of the force is opposite the displacement of the particle.

Substituting for F_x yields:

$$W_{\text{net, ext}} = \int_{3.0\,\text{m}}^{1.5\,\text{m}} -Cx^3 dx = -C\int_{3.0\,\text{m}}^{1.5\,\text{m}} x^3 dx$$

Evaluate the integral to obtain:

$$W_{\text{net, ext}} = -\left(0.50\,\frac{\text{N}}{\text{m}^3}\right)\left[\tfrac{1}{4}x^4\right]_{3.0\,\text{m}}^{1.5\,\text{m}} = -\tfrac{1}{4}\left(0.50\,\frac{\text{N}}{\text{m}^3}\right)\left[(1.5\,\text{m})^4 - (3.0\,\text{m})^4\right] = 9.492\text{ J}$$
$$= \boxed{9.5\text{ J}}$$

(*c*) Apply the work-kinetic-energy theorem to obtain:

$$W_{\text{net, ext}} = \Delta K = K_{1.5\,\text{m}} - K_{3.0\,\text{m}}$$

Substituting for $K_{1.5\,\text{m}}$ and $K_{3.0\,\text{m}}$ yields:

$$W_{\text{net, ext}} = \tfrac{1}{2}mv_{1.5\,\text{m}}^2 - \tfrac{1}{2}mv_{3.0\,\text{m}}^2$$

Solve for $v_{1.5\,\text{m}}$ to obtain:

$$v_{1.5\,\text{m}} = \sqrt{v_{3.0\,\text{m}}^2 + \frac{2W_{\text{net, ext}}}{m}} \qquad (1)$$

Substitute numerical values and evaluate $v_{3.0\,\text{m}}$:

$$v_{1.5\,\text{m}} = \sqrt{(12\ \text{m/s})^2 + \frac{2(9.49\ \text{J})}{1.5\ \text{kg}}} = \boxed{13\ \text{m/s}}$$

No. All we can conclude is that the particle gained kinetic energy.

31 •• You have a vacation cabin that has a nearby solar (black) water container used to provide a warm outdoor shower. For a few days last summer, your pump went out and you had to personally haul the water up the 4.0 m from the pond to the tank. Suppose your bucket has a mass of 5.0 kg and holds 15.0 kg of water when it is full. However, the bucket has a hole in it, and as you moved it vertically at a constant speed *v*, water leaked out at a constant rate. By the time you reached the top, only 5.0 kg of water remained. (*a*) Write an expression for the mass of the bucket plus water as a function of the height climbed above the pond surface. (*b*) Find the work done by you on the bucket for each 5.0 kg of water delivered to the tank.

Comment: DAVID: I halved all the masses because the original values were too large to be realisticl

Picture the Problem We can express the mass of the water in your bucket as the difference between its initial mass and the product of the rate at which it loses water and your position during your climb. Because you must do work against gravity in lifting and carrying the bucket, the work you do is the integral of the product of the gravitational field and the mass of the bucket as a function of its position.

(*a*) Express the mass of the bucket and the water in it as a function of its initial mass, the rate at which it is losing water, and your position, *y*, during your climb:

$$m(y) = 20.0\,\text{kg} - ry$$

Find the rate, $r = \dfrac{\Delta m}{\Delta y}$, at which your bucket loses water:

$$r = \frac{\Delta m}{\Delta y} = \frac{10.0\,\text{kg}}{4.0\,\text{m}} = 2.5\,\text{kg/m}$$

Substitute for *r* to obtain:

$$m(y) = \boxed{20.0\,\text{kg} - \left(2.5\frac{\text{kg}}{\text{m}}\right)y}$$

(b) Integrate the force you exert on the bucket, $m(y)g$, between the limits of $y = 0$ and $y = 4.0$ m:

$$W = g\int_0^{4.0\,\text{m}}\left(20.0\,\text{kg} - \left(2.5\frac{\text{kg}}{\text{m}}\right)y\right)dy$$

$$= \left(9.81\,\text{m/s}^2\right)\left[\left(20.0\,\text{kg}\right)y - \tfrac{1}{2}\left(2.5\,\text{kg/m}\right)y^2\right]_0^{4.0\,\text{m}}$$

$$= \boxed{0.59\,\text{kJ}}$$

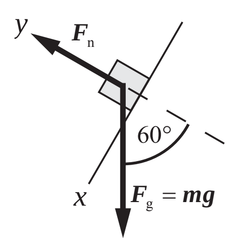
Remarks: We could also find the work you did on the bucket, at least approximately, by plotting a graph of *m*(*y*)*g* and finding the area under this curve between *y* = 0 and *y* = 4.0 m.

32 •• A 6.0-kg block slides 1.5 m down a frictionless incline that makes an angle of 60º with the horizontal. (a) Draw the free-body diagram of the block, and find the work done by each force when the block slides 1.5 m (measured along the incline). (b) What is the total work done on the block? (c) What is the speed of the block after it has slid 1.5 m, if it starts from rest? (d) What is its speed after 1.5 m, if it starts with an initial speed of 2.0 m/s?

Comment: DAVID: In 34 I changed 2.0 m to 1.5 m.

Picture the Problem We can use the definition of work as the scalar product of force and displacement to find the work done by each force acting on the block. When we have determined the work done on the block, we can use the work-kinetic energy theorem the find the speed of the block at any given location and for any initial kinetic energy it may have.

(a) The forces acting on the block are a gravitational force, exerted by Earth, that acts downward, and a normal force, exerted by the incline, that is perpendicular to the incline.



The work done by $\vec{F}_g$ is given by:

$$W_{F_g} = \vec{F}_g \cdot \vec{s} = F_g s\cos\theta$$

where $\vec{s}$ is the displacement of the block and θ is the angle between $\vec{F}_g$ and $\vec{s}$.

Substituting for F_g yields:

$$W_{F_g} = mgs\cos\theta$$

Substitute numerical values and evaluate W_{F_g}:

$$W_{F_g} = (6.0\,\text{kg})(9.81\,\text{m/s}^2)(1.5\,\text{m})\cos 30° = 76.46\,\text{J} = \boxed{76\,\text{J}}$$

The work done by $\vec{F}_n$ is given by:

$$W_{F_n} = \vec{F}_n \cdot \vec{s} = F_n s \cos\theta$$

where $\vec{s}$ is the displacement of the block and θ is the angle between $\vec{F}_n$ and $\vec{s}$.

Substitute numerical values and evaluate W_{F_n}:

$$W_{F_n} = F_n(1.5\,\text{m})\cos 90° = \boxed{0}$$

(*b*) The total work done on the block is the sum of the work done by $\vec{F}_n$ and the work done by $\vec{F}_g$:

$$W_{\text{tot}} = W_{F_g} + W_{F_n}$$

Substitute numerical values and evaluate W_{tot}:

$$W_{\text{tot}} = 0 + 76\,\text{J} = \boxed{76\,\text{J}}$$

(*c*) Apply the work-kinetic energy theorem to the block to obtain:

$$W_{F_g} = \Delta K = K_f - K_i \qquad (1)$$

or, because $v_i = 0$,

$$W_{F_g} = K_f$$

Substituting for W_{F_g} (from Part (*b*)) and K_f yields:

$$mgs\cos\theta = \tfrac{1}{2}mv_f^2 \Rightarrow v_f = \sqrt{2gs\cos\theta}$$

Substitute numerical values and evaluate v_f for $s = 1.5$ m:

$$v_f = \sqrt{2(9.81\,\text{m/s}^2)(1.5\,\text{m})\cos 30°} = \boxed{5.0\,\text{m/s}}$$

(*d*) If $K_i \neq 0$, equation (1) becomes:

$$W_{F_g} = K_f - K_i = \tfrac{1}{2}mv_f^2 - mv_i^2$$

Solving for v_f and simplifying yields:

$$v_f = \sqrt{2gs\cos\theta + v_i^2}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{2(9.81\,\text{m/s}^2)(1.5\,\text{m})\cos 30° + (2.0\,\text{m/s})^2} = \boxed{5.4\,\text{m/s}}$$

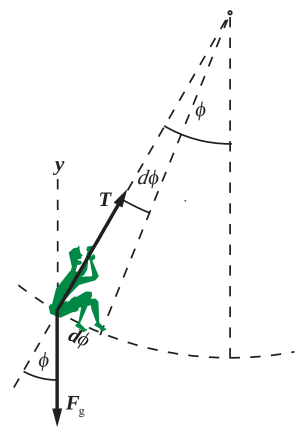
33 •• [SSM] You are designing a jungle-vine–swinging sequence for the latest Tarzan movie. To determine his speed at the low point of the swing and to make sure it does not exceed mandatory safety limits, you decide to model the system of Tarzan + vine as a pendulum. Assume your model consists of a particle (Tarzan, mass 100 kg) hanging from a light string (the vine) of length ℓ attached to a support. The angle between the vertical and the string is written as ϕ. (*a*) Draw a free-body diagram for the object on the end of the string (Tarzan on the vine). (*b*) An infinitesimal distance along the arc (along which the object travels) is $\ell d\phi$. Write an expression for the total work dW_{total} done on the particle as it traverses that distance for an arbitrary angle ϕ. (*c*) If the ℓ = 7.0 m, and if the particle starts from rest at an angle 50°, determine the particle's kinetic energy and speed at the low point of the swing using the work–kinetic-energy theorem.

Comment: DAVID: I changed *l* to ℓ and object to particle.

Comment: DAVID: I changed *l* to ℓ and object to particle.

Picture the Problem Because Tarzan's displacement is always perpendicular to the tension force exerted by the rope, this force can do no work on him. The net work done on Tarzan is the work done by the gravitational force acting on him. We can use the definition of work and the work-kinetic energy theorem to find his kinetic energy and speed at the low point of his swing.

(*a*) The forces acting on Tarzan are a gravitational force $\vec{F}_g$ (his weight) exerted by Earth and the tension force $\vec{T}$ exerted by the vine on which he is swinging.



(*b*) The work dW_{total} done by the gravitational force $\vec{F}_g$ as Tarzan swings through an arc of length ds is:

$$dW_{\text{total}} = \vec{F}_g \cdot d\vec{s} = F_g\, ds \cos(90° - \phi) = F_g\, ds \sin\phi$$

Note that, because $d\phi$ is decreasing as Tarzan swings toward his equilibrium position:

$$ds = -\ell d\phi$$

Substituting for ds and F_g yields:

$$dW_{\text{total}} = \boxed{-mg\ell \sin\phi\, d\phi}$$

(*c*) Apply the work-kinetic energy theorem to Tarzan to obtain:

$$W_{\text{total}} = \Delta K = K_{\text{f}} - K_{\text{i}}$$

or, because $K_{\text{i}} = 0$,

$$W_{\text{total}} = K_{\text{f}}$$

Substituting for W_{total} yields:

$$K_{\text{f}} = -\int_{50°}^{0°} mg\ell \sin\phi \, d\phi = -mg\ell\left[-\cos\phi\right]_{50°}^{0°}$$

Substitute numerical values and evaluate the integral to find K_{f}:

$$\begin{aligned} K_{\text{f}} &= -(100\text{ kg})(9.81\text{ m/s}^2)(7.0\text{ m})\left[-\cos\phi\right]_{50°}^{0°} \\ &= (100\text{ kg})(9.81\text{ m/s}^2)(7.0\text{ m})(1-\cos 50°) \\ &= 2.453\text{ kJ} = \boxed{2.5\text{ kJ}} \end{aligned}$$

Express K_{f} as a function of v_{f}:

$$K_{\text{f}} = \tfrac{1}{2}mv_{\text{f}}^2 \Rightarrow v_{\text{f}} = \sqrt{\frac{2K_{\text{f}}}{m}}$$

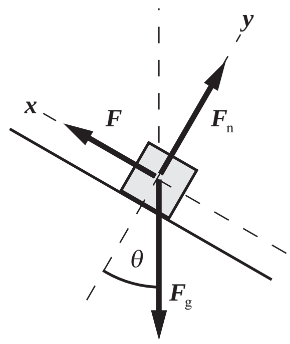
Substitute numerical values and evaluate v_{f}:

$$v_{\text{f}} = \sqrt{\frac{2(2.453\text{ kJ})}{100\text{ kg}}} = \boxed{7.0\text{ m/s}}$$

34 •• *Simple machines* are frequently used for reducing the amount of force that must be supplied to perform a task such as lifting a heavy weight. Such machines include the screw, block-and-tackle systems, and levers, but the simplest of the simple machines is the inclined plane. In Figure 6-32, you are raising a heavy box to the height of the truck bed by pushing it up an inclined plane (a ramp). (*a*) The *mechanical advantage MA* of the inclined plane is defined as the ratio of the magnitude of the force it would take to lift the block straight up (at constant speed) to the magnitude of the force it would take to push it up the ramp (at constant speed). If the plane is frictionless, show that $MA = 1/\sin\theta = L/H$, where H is the height of the truck bed and L is the length of the ramp. (*b*) Show that the work you do by moving the block into the truck is the same whether you lift it straight up or push it up the frictionless ramp.

Comment: DAVID: In 36 changed M to MA.

Picture the Problem The free-body diagram, with $\vec{F}$ representing the force required to move the block at constant speed, shows the forces acting on the block. We can apply Newton's second law to the block to relate F to its weight w and then use the definition of the mechanical advantage of an inclined plane. In the second part of the problem we'll use the definition of work.



(*a*) Express the mechanical advantage MA of the inclined plane:

$$MA = \frac{F_g}{F} \quad (1)$$

Apply $\sum F_x = ma_x$ to the block:

$$F - F_g \sin\theta = ma_x$$

or, because $a_x = 0$,

$$F - F_g \sin\theta = 0 \Rightarrow F = F_g \sin\theta$$

Substitute for F in equation (1) and simplify to obtain:

$$MA = \frac{F_g}{F_g \sin\theta} = \boxed{\frac{1}{\sin\theta}} \quad (2)$$

Refer to the figure to obtain:

$$\sin\theta = \frac{H}{L}$$

Substitute for $\sin\theta$ in equation (2) and simplify to obtain:

$$MA = \frac{1}{\frac{H}{L}} = \boxed{\frac{L}{H}}$$

(*b*) The work you do pushing the block up the ramp is given by:

$$W_{\text{ramp}} = FL$$

Because $F = F_g \sin\theta$ and $F_g = mg$:

$$W_{\text{ramp}} = (F_g \sin\theta)L = mgL\sin\theta$$

The work you do lifting the block into the truck is given by:

$$W_{\text{lifting}} = F_g H$$

Because $F_g = mg$ and $H = L\sin\theta$:

$$W_{\text{lifting}} = mgL\sin\theta \Rightarrow \boxed{W_{\text{ramp}} = W_{\text{lifting}}}$$

35 •• Particle a has mass m, is initially located on the positive x axis at $x = x_0$ and is subject to a repulsive force F_x from particle b. The location of particle b is fixed at the origin. The force F_x is inversely proportional to the square of the distance x between the particles. That is, $F_x = A/x^2$, where A is a positive constant. Particle a is released from rest and allowed to move under the influence of the

force. Find an expression for the work done by the force on a as a function of x. Find both the kinetic energy and speed of a as x approaches infinity.

Picture the Problem Because the force varies inversely with distance, we need to use the integral form of the expression for the work done on the particle. We can then apply the work-kinetic energy theorem to the particle to find its kinetic energy and speed as functions of x.

The work done by the force on the particle is given by:

$$W_{x_0\to x}=\int_{x_0}^{x}\vec{\boldsymbol{F}}\cdot dx\hat{\boldsymbol{i}}=\int_{x_0}^{x}F(\cos\theta)dx$$

where θ is the angle between $\vec{\boldsymbol{F}}$ and $dx\hat{i}$.

Substituting for F and noting that $\theta = 0$:

$$W_{x_0\to x}=\int_{x_0}^{x}\frac{A}{x^2}(\cos 0°)dx=A\int_{x_0}^{x}\frac{1}{x^2}dx$$

Evaluate this integral to obtain:

$$W_{x_0\to x}=-A\left[\frac{1}{x}\right]_{x_0}^{x}=\boxed{\frac{A}{x_0}-\frac{A}{x}}$$

Applying the work-kinetic energy theorem to the particle yields:

$$W_{x_0\to x}=\Delta K=K_x-K_{x_0}$$

or, because the particle is released from rest at $x = x_0$,

$$W_{x_0\to x}=K_x$$

Substitute for $W_{x_0\to x}$ to obtain:

$$K_x=\frac{A}{x_0}-\frac{A}{x}$$

As $x\to\infty$:

$$K_{x\to\infty}=\boxed{\frac{A}{x_0}}$$

and

$$v_{x\to\infty}=\sqrt{\frac{2K_{x\to}}{m}}=\sqrt{\frac{2\left(\frac{A}{x_0}\right)}{m}}=\boxed{\sqrt{\frac{2A}{mx_0}}}$$

36 •• You exert a force of magnitude F on the free end of the rope. If the load moves up a distance h, (*a*) through what distance does the point of application of the force move? (*b*) How much work is done by the rope on the load? (*c*) How much work do you do on the rope? (*d*) The mechanical advantage (defined in Problem 34) of this system is the ratio F/F_g, where F_g is the weight of the load. What is this mechanical advantage?

Comment: AU: Italic F OK? Or should it have an arrow over it as the F in the figure does?

Picture the Problem The object whose weight is $\vec{w}$ is supported by two portions of the rope resulting in what is known as a *mechanical advantage* of 2. The work that is done in each instance is the product of the force doing the work and the displacement of the object on which it does the work.

(*a*) If w moves through a distance h: The point of application of F moves a distance $\boxed{2h}$.

(*b*) Assuming that the kinetic energy of the weight does not change, relate the work done on the object to the change in its potential energy to obtain:

$$W = \Delta U = wh\cos\theta = \boxed{wh}$$

(*c*) Because the force you exert on the rope and its displacement are in the same direction:

$$W = F(2h)\cos\theta = F(2h)$$

Determine the tension in the ropes supporting the object:

$$\sum F_{\text{vertical}} = 2F - w = 0 \Rightarrow F = \tfrac{1}{2}w$$

Substitute for F:

$$W = F(2h) = \tfrac{1}{2}w(2h) = \boxed{wh}$$

(*d*) The mechanical advantage of the pulley-rope system is the ratio of the weight that is lifted to the force required to lift it, that is:

$$MA = \frac{w}{F} = \frac{w}{\frac{1}{2}w} = \boxed{2}$$

Remarks: Note that the mechanical advantage is also equal to the number of ropes supporting the load.

Scalar (Dot) Products

37 • What is the angle between the vectors $\vec{A}$ and $\vec{B}$ if $\vec{A}\cdot\vec{B} = -AB$?

Picture the Problem Because $\vec{A}\cdot\vec{B} = AB\cos\theta$, we can solve for $\cos\theta$ and use the fact that $\vec{A}\cdot\vec{B} = -AB$ to find θ.

Solve $\vec{A}\cdot\vec{B} = AB\cos\theta$, for θ to obtain:

$$\theta = \cos^{-1}\left(\frac{\vec{A}\cdot\vec{B}}{AB}\right)$$

Substitute for $\vec{A}\cdot\vec{B}$ and evaluate θ:

$$\theta = \cos^{-1}\left(\frac{-AB}{AB}\right) = \cos^{-1}(-1) = \boxed{180°}$$

38 • Two vectors $\vec{A}$ and $\vec{B}$ each have magnitudes of 6.0 m and the angle between their directions is 60º. Find $\vec{A}\cdot\vec{B}$.

Picture the Problem We can use the definition of the scalar product to evaluate $\vec{A}\cdot\vec{B}$.

Express the definition of the scalar product $\vec{A}\cdot\vec{B}$:

$$\vec{A}\cdot\vec{B} = AB\cos\theta$$

Substitute numerical values and evaluate $\vec{A}\cdot\vec{B}$:

$$\vec{A}\cdot\vec{B} = (6.0\,\text{m})(6.0\,\text{m})\cos 60° = \boxed{18\,\text{m}^2}$$

39 • Find $\vec{A}\cdot\vec{B}$ for the following vectors: (*a*) $\vec{A} = 3\hat{i} - 6\hat{j}$, $\vec{B} = -4\hat{i} + 2\hat{j}$; (*b*) $\vec{A} = 5\hat{i} + 5\hat{j}$, $\vec{B} = 2\hat{i} - 4\hat{j}$; and (*c*) $\vec{A} = 6\hat{i} + 4\hat{j}$, $\vec{B} = 4\hat{i} - 6\hat{j}$.

Picture the Problem The scalar product of two-dimensional vectors $\vec{A}$ and $\vec{B}$ is $A_xB_x + A_yB_y$.

(*a*) For $\vec{A} = 3\hat{i} - 6\hat{j}$ and $\vec{B} = -4\hat{i} + 2\hat{j}$:

$$\vec{A}\cdot\vec{B} = (3)(-4) + (-6)(2) = \boxed{-24}$$

(*b*) For $\vec{A} = 5\hat{i} + 5\hat{j}$ and $\vec{B} = 2\hat{i} - 4\hat{j}$:

$$\vec{A}\cdot\vec{B} = (5)(2) + (5)(-4) = \boxed{-10}$$

(*c*) For $\vec{A} = 6\hat{i} + 4\hat{j}$ and $\vec{B} = 4\hat{i} - 6\hat{j}$:

$$\vec{A}\cdot\vec{B} = (6)(4) + (4)(-6) = \boxed{0}$$

40 • Find the angles between the vectors $\vec{A}$ and $\vec{B}$ given: (*a*) $\vec{A} = 3\hat{i} - 6\hat{j}$, $\vec{B} = -4\hat{i} + 2\hat{j}$; (*b*) $\vec{A} = 5\hat{i} + 5\hat{j}$, $\vec{B} = 2\hat{i} - 4\hat{j}$; and (*c*) $\vec{A} = 6\hat{i} + 4\hat{j}$, $\vec{B} = 4\hat{i} - 6\hat{j}$.

Picture the Problem The scalar product of two-dimensional vectors $\vec{A}$ and $\vec{B}$ is $AB\cos\theta = A_xB_x + A_yB_y$. Hence the angle between vectors $\vec{A}$ and $\vec{B}$ is given by

$$\theta = \cos^{-1}\left(\frac{A_xB_x + A_yB_y}{AB}\right).$$

(*a*) For $\vec{A} = 3\hat{i} - 6\hat{j}$ and $\vec{B} = -4\hat{i} + 2\hat{j}$:

$$\theta = \cos^{-1}\left(\frac{(3)(-4)+(-6)(2)}{\sqrt{3^2+(-6)^2}\sqrt{(-4)^2+(2)^2}}\right) = \boxed{143°}$$

(*b*) For $\vec{A} = 5\hat{i} + 5\hat{j}$ and $\vec{B} = 2\hat{i} - 4\hat{j}$:

$$\theta = \cos^{-1}\left(\frac{(5)(2)+(5)(-4)}{\sqrt{5^2+5^2}\sqrt{2^2+(-4)^2}}\right) = \boxed{108°}$$

(*c*) For $\vec{A} = 6\hat{i} + 4\hat{j}$ and $\vec{B} = 4\hat{i} - 6\hat{j}$:

$$\theta = \cos^{-1}\left(\frac{(6)(4)+(4)(-6)}{\sqrt{6^2+4^2}\sqrt{4^2+(-6)^2}}\right) = \boxed{90°}$$

41 • A 2.0-kg particle is given a displacement of $\Delta\vec{r} = (3.0\text{ m})\hat{i} + (3.0\text{ m})\hat{j} + (-2.0\text{ m})\hat{k}$. During the displacement, a constant force $\vec{F} = (2.0\text{ N})\hat{i} - (1.0\text{ N})\hat{j} + (1.0\text{ N})\hat{k}$ acts on the particle. (*a*) Find the work done by $\vec{F}$ for this displacement. (*b*) Find the component of $\vec{F}$ in the direction of this displacement.

Picture the Problem The work *W* done by a force $\vec{F}$ during a displacement $\Delta\vec{s}$ for which it is responsible is given by $\vec{F}\cdot\Delta\vec{r}$.

(*a*) Using the definitions of work and the scalar product, calculate the work done by the given force during the specified displacement:

$$\begin{aligned} W &= \vec{F}\cdot\Delta\vec{r} = \left[(2.0\text{ N})\hat{i} - (1.0\text{ N})\hat{j} + (1.0\text{ N})\hat{k}\right]\cdot\left[(3.0\text{ m})\hat{i} + (3.0\text{ m})\hat{j} - (2.0\text{ m})\hat{k}\right] \\ &= [(2.0)(3.0) + (-1.0)(3.0) + (1.0)(-2.0)]\text{N}\cdot\text{m} = \boxed{1.0\text{ J}} \end{aligned}$$

(*b*) Use the definition of work that includes the angle between the force and displacement vectors to express the work done by $\vec{F}$:

$$W = F\Delta r\cos\theta = (F\cos\theta)\Delta r$$

Solve for the component of $\vec{F}$ in the direction of $\Delta\vec{r}$:

$$F\cos\theta = \frac{W}{\Delta r}$$

Substitute numerical values and evaluate $F\cos\theta$:

$$F\cos\theta = \frac{1.0\,\text{J}}{\sqrt{(3.0\,\text{m})^2 + (3.0\,\text{m})^2 + (-2.0\,\text{m})^2}} = \boxed{0.21\,\text{N}}$$

42 •• (*a*) Find the unit vector that is in the same direction as the vector $\vec{A} = 2.0\hat{i} - 1.0\hat{j} - 1.0\hat{k}$. (*b*) Find the component of the vector $\vec{A} = 2.0\hat{i} - 1.0\hat{j} - 1.0\hat{k}$ in the direction of the vector $\vec{B} = 3.0\hat{i} + 4.0\hat{j}$.

Picture the Problem A unit vector that is in the same direction as a given vector and is the given vector divided by its magnitude. The component of a vector that is in the direction of another vector is the scalar product of the former vector and a unit vector that is in the direction of the latter vector.

(*a*) By definition, the unit vector that is in the same direction as $\vec{A}$ is:

$$\hat{u}_A = \frac{\vec{A}}{A}$$

Substitute for $\vec{A}$ and A and evaluate $\hat{u}_A$:

$$\hat{u}_A = \frac{2.0\hat{i} - 1.0\hat{j} - 1.0\hat{k}}{\sqrt{(2.0)^2 + (-1.0)^2 + (-1.0)^2}} = \frac{2.0\hat{i} - 1.0\hat{j} - 1.0\hat{k}}{\sqrt{6}} = \boxed{0.82\hat{i} - 0.41\hat{j} - 0.41\hat{k}}$$

(*b*) The component of $\vec{A}$ in the direction of $\vec{B}$ is given by:

$$A_{\substack{\text{direction}\\ \text{of } \vec{B}}} = \vec{A}\cdot\hat{u}_B \qquad (1)$$

The unit vector in the direction of $\vec{B}$ is:

$$\hat{u}_B = \frac{\vec{B}}{B} = \frac{3.0\hat{\mathbf{i}} + 4.0\hat{\mathbf{j}}}{\sqrt{(3.0)^2 + (4.0)^2}} = \frac{3}{5}\hat{\mathbf{i}} + \frac{4}{5}\hat{\mathbf{j}}$$

Substitute for $\vec{B}$ and $\hat{u}_B$ in equation (1) and evaluate $A_{\substack{\text{direction}\\ \text{of } \vec{B}}}$:

$$A_{\substack{\text{direction}\\ \text{of } \vec{B}}} = \left(2.0\hat{i} - 1.0\hat{j} - 1.0\hat{k}\right)\cdot\left(\frac{3}{5}\hat{i} + \frac{4}{5}\hat{j}\right) = (2.0)\left(\frac{3}{5}\right) + (-1.0)\left(\frac{4}{5}\right) + (-1.0)(0) = \boxed{0.40}$$

43 •• **[SSM]** (*a*) Given two nonzero vectors $\vec{A}$ and $\vec{B}$, show that if $\left|\vec{A}+\vec{B}\right|=\left|\vec{A}-\vec{B}\right|$, then $\vec{A}\perp\vec{B}$. (*b*) Given a vector $\vec{A}=4\hat{i}-3\hat{j}$, find a vector in the *xy* plane that is perpendicular to $\vec{A}$ and has a magnitude of 10. Is this the only vector that satisfies the specified requirements? Explain.

Picture the Problem We can use the definitions of the magnitude of a vector and the dot product to show that if $\left|\vec{A}+\vec{B}\right|=\left|\vec{A}-\vec{B}\right|$, then $\vec{A}\perp\vec{B}$.

(*a*) Express $\left|\vec{A}+\vec{B}\right|^2$:

$$\left|\vec{A}+\vec{B}\right|^2=\left(\vec{A}+\vec{B}\right)^2$$

Express $\left|\vec{A}-\vec{B}\right|$:

$$\left|\vec{A}-\vec{B}\right|^2=\left(\vec{A}-\vec{B}\right)^2$$

Equate these expressions to obtain:

$$\left(\vec{A}+\vec{B}\right)^2=\left(\vec{A}-\vec{B}\right)^2$$

Expand both sides of the equation to obtain:

$$A^2+2\vec{A}\cdot\vec{B}+B^2=A^2-2\vec{A}\cdot\vec{B}+B^2$$

Simplify to obtain:

$$4\vec{A}\cdot\vec{B}=0 \text{ or } \vec{A}\cdot\vec{B}=0$$

From the definition of the dot product we have:

$$\vec{A}\cdot\vec{B}=AB\cos\theta$$

where θ is the angle between $\vec{A}$ and $\vec{B}$.

Because neither $\vec{A}$ nor $\vec{B}$ is the zero vector:

$$\cos\theta=0 \Rightarrow \theta=90° \text{ and } \vec{A}\perp\vec{B}.$$

(*b*) Let the required vector be $\vec{B}$. The condition that $\vec{A}$ and $\vec{B}$ be perpendicular is that:

$$\vec{A}\cdot\vec{B}=0 \qquad (1)$$

Express $\vec{B}$ as:

$$\vec{B}=B_x\hat{i}+B_y\hat{j} \qquad (2)$$

Substituting for $\vec{A}$ and $\vec{B}$ in equation (1) yields:

$$\left(4\hat{i}-3\hat{j}\right)\cdot\left(B_x\hat{i}+B_y\hat{j}\right)=0$$

or

$$4B_x-3B_y=0 \qquad (3)$$

Because the magnitude of $\vec{B}$ is 10:

$$B_x^2+B_y^2=100 \qquad (4)$$

Solving equation (3) for B_x and substituting in equation (4) yields:

$$\left(\tfrac{3}{4}B_y\right)^2+B_y^2=100$$

Solve for B_y to obtain:

$$B_y = \pm 8$$

Substituting for B_y in equation (3) and solving for B_x yields:

If $B_y = +8$, then $B_x = +6$.
If $B_y = -8$, then $B_x = -6$

Substitute for B_x and B_y in equation (2) to obtain:

$$\vec{B} = \boxed{6\hat{i} + 8\hat{j}}$$

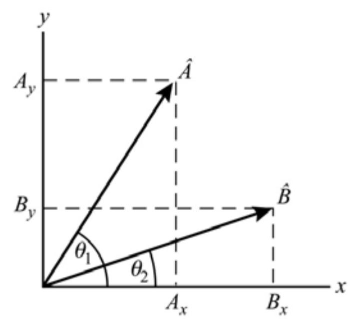
or

$$\vec{B} = \boxed{-6\hat{i} - 8\hat{j}}$$

No. There are two possibilities. The vectors point in opposite directions. One vector is in the 1st quadrant and the other vector is in the 3rd quadrant.

44 •• Unit vectors $\hat{A}$ and $\hat{B}$ are in the *xy* plane. They make angles of θ_1 and θ_2, respectively, with the +*x* axis, respectively. (*a*) Use trigonometry to find the *x* and *y* components of the two vectors directly. (Your answer should be in terms of the angles.) (*b*) By considering the scalar product of $\hat{A}$ and $\hat{B}$, show that $\cos(\theta_1 - \theta_2) = \cos\theta_1 \cos\theta_2 + \sin\theta_1 \sin\theta_2$.

Picture the Problem The diagram shows the unit vectors $\hat{A}$ and $\hat{B}$ arbitrarily located in the 1st quadrant. We can express these vectors in terms of the unit vectors $\hat{i}$ and $\hat{j}$ and their *x* and *y* components. We can then form the scalar product of $\hat{A}$ and $\hat{B}$ to show that $\cos(\theta_1 - \theta_2) = \cos\theta_1\cos\theta_2 + \sin\theta_1\sin\theta_2$.



(*a*) Express $\hat{A}$ in terms of the unit vectors $\hat{i}$ and $\hat{j}$:

$$\hat{A} = A_x\hat{i} + A_y\hat{j}$$

where

$$A_x = \boxed{\cos\theta_1} \text{ and } A_y = \boxed{\sin\theta_1}$$

Proceed as above to obtain:

$$\hat{B} = B_x\hat{i} + B_y\hat{j}$$

where

$$B_x = \boxed{\cos\theta_2} \text{ and } B_y = \boxed{\sin\theta_2}$$

(*b*) Evaluate $\hat{A}\cdot\hat{B}$:

$$\begin{aligned}\hat{A}\cdot\hat{B} &= \left(\cos\theta_1\hat{i} + \sin\theta_1\hat{j}\right) \\ &\quad\cdot\left(\cos\theta_2\hat{i} + \sin\theta_2\hat{j}\right) \\ &= \cos\theta_1\cos\theta_2 + \sin\theta_1\sin\theta_2\end{aligned}$$

From the diagram we note that: $\hat{\boldsymbol{A}}\cdot\hat{\boldsymbol{B}}=\cos(\theta_1-\theta_2)$

Substitute for $\hat{\boldsymbol{A}}\cdot\hat{\boldsymbol{B}}$ to obtain $\boxed{\cos(\theta_1-\theta_2)=\cos\theta_1\cos\theta_2+\sin\theta_1\sin\theta_2}$.

45 •• In Chapter 8, we shall introduce a new vector for a particle, called its *linear momentum*, symbolized by $\vec{\boldsymbol{p}}$. Mathematically, it is related to the mass m and velocity $\vec{\mathbf{v}}$ of the particle by $\vec{\boldsymbol{p}}=m\vec{\mathbf{v}}$. (*a*) Show that the particle's kinetic energy K can be expressed as $K=\dfrac{\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{p}}}{2m}$. (*b*) Compute the linear momentum of a particle of mass 2.5 kg that is moving at a speed of 15 m/s at an angle of 25° clockwise from the +*x* axis in the *xy* plane. (*c*) Compute its kinetic energy using both $K=\frac{1}{2}mv^2$ and $K=\dfrac{\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{p}}}{2m}$ and verify that they give the same result.

Picture the Problem The scalar product of two vectors is the product of their magnitudes multiplied by the cosine of the angle between them.

(*a*) We're to show that:

$$K=\frac{\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{p}}}{2m}\qquad(1)$$

The scalar product of $\vec{\boldsymbol{p}}$ with itself is: $\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{p}}=p^2$

Because $p = mv$: $\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{p}}=m^2v^2$

Substitute in equation (1) and simplify to obtain:

$$K=\frac{m^2v^2}{2m}=\boxed{\tfrac{1}{2}mv^2}$$

(*b*) The linear momentum of the particle is given by: $\vec{\boldsymbol{p}}=m\vec{\mathbf{v}}$

Substitute numerical values for m and $\vec{\mathbf{v}}$ and simplify to obtain:

$$\begin{aligned}\vec{\boldsymbol{p}}&=(2.5\text{ kg})\left[\{(15\text{ m/s})\cos 335°\}\hat{\boldsymbol{i}}+\{(15\text{ m/s})\sin 335°\}\hat{\boldsymbol{j}}\right]\\&=\boxed{(34\text{ kg}\cdot\text{m/s})\hat{\boldsymbol{i}}+(-16\text{ kg}\cdot\text{m/s})\hat{\boldsymbol{j}}}\end{aligned}$$

(*c*) Evaluating $K=\frac{1}{2}mv^2$ yields: $K=\frac{1}{2}(2.5\text{ kg})(15\text{ m/s})^2=\boxed{0.28\text{ kJ}}$

Evaluating $K = \dfrac{\vec{p}\cdot\vec{p}}{2m}$ yields:

$$K = \frac{\left[(34\text{ m/s})\hat{i} + (-16\text{ m/s})\hat{j}\right]\cdot\left[(34\text{ m/s})\hat{i} + (-16\text{ m/s})\hat{j}\right]}{2(2.5\text{ kg})}$$
$$= \frac{(34\text{ m/s})^2 + (-16\text{ m/s})^2}{5.0\text{ kg}} = \boxed{0.28\text{ kJ}}$$

46 •• (a) Let $\vec{A}$ be a constant vector in the xy plane with its tail at the origin. Let $\vec{r} = x\hat{i} + y\hat{j}$ be a vector in the xy plane that satisfies the relation $\vec{A}\cdot\vec{r} = 1$. Show that the points with coordinates (x,y) lie on a straight line. (b) If $\vec{A} = 2\hat{i} - 3\hat{j}$, find the slope and y intercept of the line. (c) If we now let $\vec{A}$ and $\vec{r}$ be vectors in three-dimensional space, show that the relation $\vec{A}\cdot\vec{r} = 1$ specifies a plane.

Picture the Problem We can form the dot product of $\vec{A}$ and $\vec{r}$ and require that $\vec{A}\cdot\vec{r} = 1$ to show that the points at the head of all such vectors $\vec{r}$ lie on a straight line. We can use the equation of this line and the components of $\vec{A}$ to find the slope and intercept of the line.

(a) Let $\vec{A} = a_x\hat{i} + a_y\hat{j}$. Then:

$$\vec{A}\cdot\vec{r} = \left(a_x\hat{i} + a_y\hat{j}\right)\cdot\left(x\hat{i} + y\hat{j}\right)$$
$$= a_x x + a_y y = 1$$

Solve for y to obtain:

$$y = \boxed{-\frac{a_x}{a_y}x + \frac{1}{a_y}}$$

which is of the form $y = mx + b$ and hence is the equation of a straight line.

(b) Given that $\vec{A} = 2\hat{i} - 3\hat{j}$:

$$m = -\frac{a_x}{a_y} = -\frac{2}{-3} = \boxed{\frac{2}{3}}$$

and

$$b = \frac{1}{a_y} = \frac{1}{-3} = \boxed{-\frac{1}{3}}$$

(c) The equation $\vec{A}\cdot\vec{r} = 1$ specifies all vectors $\vec{r}$ whose component r_A (the component of $\vec{r}$ parallel to $\vec{A}$) has the constant magnitude A^{-1}.

$$1 = \vec{A}\cdot\vec{r} = A\hat{A}\cdot\vec{r} = A\left(\vec{r}\cdot\hat{A}\right) = Ar_A$$

so

$$\frac{1}{A} = r_A$$

Let $\vec{B}$ represent all vectors $\vec{r}$ such that $\vec{r} = A^{-1}\hat{A} + \vec{B}$. Multiplying both sides by $\hat{A}$ shows that $\vec{B}$ is perpendicular to $\vec{A}$:

$$\begin{aligned}\vec{r}\cdot\hat{A} &= \left(A^{-1}\hat{A} + \vec{B}\right)\cdot\hat{A}\\ &= A^{-1}\hat{A}\cdot\hat{A} + \vec{B}\cdot\hat{A}\\ &= A^{-1} + \vec{B}\cdot\hat{A}\end{aligned}$$

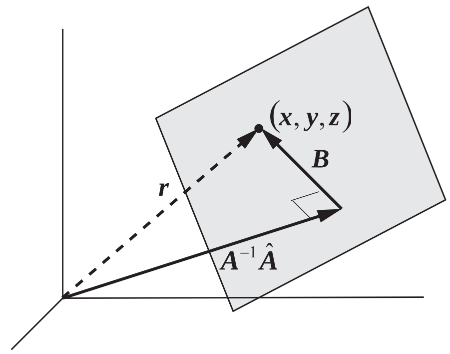
Because $\vec{r}\cdot\hat{A} = r_{\mathrm{A}} = A^{-1}$:

$$A^{-1} = A^{-1} + \vec{B}\cdot\hat{A} \Rightarrow \vec{B}\cdot\hat{A} = 0$$

Because $\vec{B}\cdot\hat{A} = 0$:

$$\vec{B} \perp \hat{A}$$

The relation $\vec{r} = A^{-1}\hat{A} + \vec{B}$ is shown graphically to the right:



From the figure we can see that the tip of $\vec{r}$ is restricted to a plane that is perpendicular to $\hat{A}$ and contains the point a distance A^{-1} from the origin in the direction of $\hat{A}$. The equation $\vec{A}\cdot\vec{r} = 1$ specifies this plane.

47 ••• [SSM] When a particle moves in a circle that is centered at the origin and the magnitude of its position vector $\vec{r}$ is constant. (*a*) Differentiate $\vec{r}\cdot\vec{r} = r^2 = \text{constant}$ with respect to time to show that $\vec{v}\cdot\vec{r} = 0$, and therefore $\vec{v}\perp\vec{r}$. (*b*) Differentiate $\vec{v}\cdot\vec{r} = 0$ with respect to time and show that $\vec{a}\cdot\vec{r} + v^2 = 0$, and therefore $a_r = -v^2/r$. (*c*) Differentiate $\vec{v}\cdot\vec{v} = v^2$ with respect to time to show that $\vec{a}\cdot\vec{v} = dv/dt$, and therefore $a_{\mathrm{t}} = dv/dt$.

Comment: DAVID: Parts (b) and (c) have been transposed, and the restrictions to constant speed have been removed throughout.

Picture the Problem The rules for the differentiation of vectors are the same as those for the differentiation of scalars and scalar multiplication is commutative.

(*a*) Differentiate $\vec{r}\cdot\vec{r} = r^2 = \text{constant}$:

$$\begin{aligned}\frac{d}{dt}\left(\vec{r}\cdot\vec{r}\right) &= \vec{r}\cdot\frac{d\vec{r}}{dt} + \frac{d\vec{r}}{dt}\cdot\vec{r} = 2\vec{v}\cdot\vec{r}\\ &= \frac{d}{dt}\left(\text{constant}\right) = 0\end{aligned}$$

Because $\vec{v}\cdot\vec{r} = 0$:

$$\boxed{\vec{v}\perp\vec{r}}$$

(*b*) Differentiate $\vec{v}\cdot\vec{r} = 0$ with respect to time:

$$\frac{d}{dt}(\vec{v}\cdot\vec{r}) = \vec{v}\cdot\frac{d\vec{r}}{dt} + \vec{r}\cdot\frac{d\vec{v}}{dt}$$

$$= v^2 + \vec{r}\cdot\vec{a} = \frac{d}{dt}(0) = 0$$

Because $v^2 + \vec{r}\cdot\vec{a} = 0$:

$$\boxed{\vec{r}\cdot\vec{a} = -v^2} \qquad (1)$$

Express a_r in terms of θ, where θ is the angle between $\vec{r}$ and $\vec{a}$:

$$a_r = a\cos\theta$$

Express $\vec{r}\cdot\vec{a}$:

$$\vec{r}\cdot\vec{a} = ra\cos\theta = ra_r$$

Substitute in equation (1) to obtain:

$$ra_r = -v^2$$

Solving for a_r yields:

$$a_r = \boxed{-\frac{v^2}{r}}$$

(*c*) Differentiate $\vec{v}\cdot\vec{v} = v^2$ with respect to time:

$$\frac{d}{dt}(\vec{v}\cdot\vec{v}) = \vec{v}\cdot\frac{d\vec{v}}{dt} + \frac{d\vec{v}}{dt}\cdot\vec{v} = 2\vec{a}\cdot\vec{v}$$

$$= \frac{d(v^2)}{dt} = 2v\frac{dv}{dt}$$

$2\vec{a}\cdot\vec{v}$ is also given by:

$$2\vec{a}\cdot\vec{v} = 2a_t v = 2v\frac{dv}{dt} \Rightarrow a_t = \frac{dv}{dt}$$

The results of (*a*) and (*b*) tell us that $\vec{a}$ is perpendicular to $\vec{v}$ and parallel (or antiparallel to $\vec{r}$.

Work and Power

48 • Force A does 5.0 J of work in 10 s. Force B does 3.0 J of work in 5.0 s. Which force delivers greater power, A or B? Explain.

Picture the Problem The average power delivered by a force is defined as the rate at which the force does work; i.e., $P_{av} = \frac{\Delta W}{\Delta t}$.

Calculate the average rate at which force *A* does work:

$$P_{A,\,av} = \frac{\Delta W}{\Delta t} = \frac{5.0\,\text{J}}{10\,\text{s}} = 0.50\,\text{W}$$

Calculate the rate at which force B does work:

$$P_{\mathrm{B,av}}=\frac{3.0\,\mathrm{J}}{5.0\,\mathrm{s}}=0.60\,\mathrm{W}$$

Force B delivers greater power because, although it does only 60% of the work force A does, it does it in 50% of the time required by force A.

49 • A single force of 5.0 N in the + x direction acts on an 8.0-kg object. (a) If the object starts from rest at x = 0 at time t = 0, write an expression for the power delivered by this force as a function of time. (b) What is the power delivered by this force at time t = 3.0 s?

Picture the Problem We can use Newton's second law and the definition of acceleration to express the velocity of this object as a function of time. The power input of the force accelerating the object is defined to be the rate at which it does work; that is, $P=dW/dt=\vec{F}\cdot\vec{v}$.

(a) The power of the force as a function of time is given by:

$$P(t)=\frac{dW}{dt}=\vec{F}\cdot\vec{v}=Fv(t)\cos\theta$$

or, because the force acts in the same direction as the velocity of the object,

$$P(t)=Fv(t) \qquad (1)$$

Express the velocity of the object as a function of its acceleration and time:

$$v(t)=at$$

Applying $\sum\vec{F}=m\vec{a}$ to the object yields:

$$a=\frac{F}{m}$$

Substitute for a in the expression for v to obtain:

$$v(t)=\frac{F}{m}t$$

Substituting in equation (1) yields:

$$P(t)=\frac{F^2}{m}t$$

Substitute numerical values and evaluate $P(t)$:

$$P(t)=\frac{(5.0\,\mathrm{N})^2}{8.0\,\mathrm{kg}}t=(3.125\,\mathrm{W/s})t$$

$$=\boxed{(3.1\,\mathrm{W/s})t}$$

(*b*) Evaluate *P*(3.0 s): $P(3.0\,\text{s}) = (3.125\,\text{W/s})(3.0\,\text{s}) = \boxed{9.4\,\text{W}}$

50 • Find the power delivered by a force $\vec{F}$ acting on a particle that moves with a velocity $\vec{v}$, where (*a*) $\vec{F} = (4.0\ \text{N})\hat{i} + (3.0\ \text{N})\hat{k}$ and $\vec{v} = (6.0\ \text{m/s})\hat{i}$;
(*b*) $\vec{F} = (6.0\ \text{N})\hat{i} - (5.0\ \text{N})\hat{j}$ and $\vec{v} = -(5.0\ \text{m/s})\hat{i} + (4.0\ \text{m/s})\hat{j}$; and
(*c*) $\vec{F} = (3.0\ \text{N})\hat{i} + (6.0\ \text{N})\hat{j}$ and $\vec{v} = (2.0\ \text{m/s})\hat{i} + (3.0\ \text{m/s})\hat{j}$.

Picture the Problem The power delivered by a force is defined as the rate at which the force does work; i.e., $P = \dfrac{dW}{dt} = \vec{F}\cdot\vec{v}$.

(*a*) For $\vec{F} =$ (4.0 N) $\hat{i}$ + (3.0 N) $\hat{k}$ and $\vec{v}$ = (6.0 m/s) $\hat{i}$:

$$P = \vec{F}\cdot\vec{v} = \left[(4.0\,\text{N})\hat{i} + (3.0\,\text{N})\hat{k}\right]\cdot\left[(6.0\,\text{m/s})\hat{i}\right] = \boxed{24\,\text{W}}$$

(*b*) For $\vec{F}$ = (6.0 N) $\hat{i}$ −(5.0 N) $\hat{j}$ and $\vec{v}$ = − (5.0 m/s) $\hat{i}$ +(4.0 m/s) $\hat{j}$:

$$P = \vec{F}\cdot\vec{v} = \left[(6.0\,\text{N})\hat{i} - (5.0\,\text{N})\hat{j}\right]\cdot\left[-(5.0\,\text{m/s})\hat{i} + (4.0\,\text{m/s})\hat{j}\right] = \boxed{-50\,\text{W}}$$

(*c*) For $\vec{F}$ = (3.0 N) $\hat{i}$ + (6.0 N) $\hat{j}$ and $\vec{v}$ = (2.0 m/s) $\hat{i}$ + (3.0 m/s) $\hat{j}$:

$$P = \vec{F}\cdot\vec{v} = \left[(3.0\,\text{N})\hat{i} + (6.0\,\text{N})\hat{j}\right]\cdot\left[(2.0\,\text{m/s})\hat{i} + (3.0\,\text{m/s})\hat{j}\right] = \boxed{24\,\text{W}}$$

51 • **[SSM]** You are in charge of installing a small food-service elevator (called a *dumbwaiter* in the food industry) in a campus cafeteria. The elevator is connected by a pulley system to a motor, as shown in Figure 6-34. The motor raises and lowers the dumbwaiter. The mass of the dumbwaiter is 35 kg. In operation, it moves at a speed of 0.35 m/s upward, without accelerating (except for a brief initial period, which we can neglect, just after the motor is turned on). Electric motors typically have an efficiency of 78%. If you purchase a motor with an efficiency of 78%, what minimum power rating should the motor have? Assume that the pulleys are frictionless.

Comment: DAVID: Efficiency changed to 78%.

Picture the Problem Choose a coordinate system in which upward is the positive *y* direction. We can find P_{in} from the given information that $\boldsymbol{P}_{\text{out}} = 0.78\boldsymbol{P}_{\text{in}}$. We can express P_{out} as the product of the tension in the cable *T* and the constant speed *v* of the dumbwaiter. We can apply Newton's second law to the dumbwaiter to express *T* in terms of its mass *m* and the gravitational field *g*.

Express the relationship between the motor's input and output power: $P_{\text{out}} = 0.78P_{\text{in}} \Rightarrow P_{\text{in}} = 1.282P_{\text{out}}$ (1)

Express the power required to move the dumbwaiter at a constant speed v:

$$P_{out} = Tv$$

Apply $\sum F_y = ma_y$ to the dumbwaiter:

$$T - mg = ma_y$$

or, because $a_y = 0$,

$$T = mg$$

Substitute for T in equation (1) to obtain:

$$P_{in} = 1.282Tv = 1.282mgv$$

Substitute numerical values and evaluate P_{in}:

$$P_{in} = (1.282)(35\,\text{kg})(9.81\,\text{m/s}^2)(0.35\,\text{m/s}) = \boxed{0.15\,\text{kW}}$$

52 •• A cannon placed at the edge of a cliff of height H fires a cannonball directly upward with an initial speed v_0. The cannonball rises, falls back down (missing the cannon by a small margin) and lands at the foot of the cliff. Neglecting air resistance, calculate the velocity $\vec{v}$ as a function of time, and show explicitly that the integral of $\vec{F}_{net} \cdot \vec{v}$ over the time that the cannonball spends in flight is equal to the change in the kinetic energy of the cannonball over the same time.

Comment: DAVID: Subscript "net" added.

Picture the Problem Because, in the absence of air resistance, the acceleration of the cannonball is constant, we can use a constant-acceleration equation to relate its velocity to the time it has been in flight. We can apply Newton's second law to the cannonball to find the net force acting on it and then form the dot product of $\vec{F}$ and $\vec{v}$ to express the rate at which the gravitational field does work on the cannonball. Integrating this expression over the time-of-flight T of the ball will yield the desired result.

Express the velocity of the cannonball as a function of time while it is in the air:

$$\vec{v}(t) = 0\hat{i} + (v_0 - gt)\hat{j} = \boxed{(v_0 - gt)\hat{j}}$$

Apply $\sum \vec{F} = m\vec{a}$ to the cannonball to express the force acting on it while it is in the air:

$$\vec{F}_{net} = -mg\,\hat{j}$$

Evaluate $\vec{F}_{net} \cdot \vec{v}$:

$$\vec{F}_{net} \cdot \vec{v} = -mg\,\hat{j} \cdot (v_0 - gt)\hat{j} = -mgv_0 + mg^2t$$

Relate $\vec{F}_{\text{net}} \cdot \vec{v}$ to the rate at which work is being done on the cannonball:

$$\frac{dW}{dt} = \vec{F}_{\text{net}} \cdot \vec{v} = -mgv_0 + mg^2t$$

Separate the variables and integrate over the time T that the cannonball is in the air:

$$W = \int_0^T \left(-mgv_0 + mg^2t\right) dt = \tfrac{1}{2}mg^2T^2 - mgv_0T \qquad (1)$$

Using a constant-acceleration equation, relate the time-of-flight T to the initial and impact speeds of the cannonball:

$$v = v_0 - gT \Rightarrow T = \frac{v_0 - v}{g}$$

Substitute for T in equation (1) and simplify to evaluate W:

$$W = \tfrac{1}{2}mg^2\,\frac{v_0^2 - 2vv_0 + v^2}{g^2} - mgv_0\left(\frac{v_0 - v}{g}\right) = \tfrac{1}{2}mv^2 - \tfrac{1}{2}mv_0^2 = \boxed{\Delta K}$$

53 •• A particle of mass m moves from rest at t = 0 under the influence of a single constant force $\vec{F}$. Show that the power delivered by the force at any time t is $P = F^2t/m$.

Comment: DAVID: Part (b) was deleted because it was circular.

Picture the Problem If the particle is acted on by a *single* force, that force is the *net* force acting on the particle and is responsible for its acceleration. The rate at which energy is delivered by the force is $P = \vec{F} \cdot \vec{v}$. We can apply the work-kinetic energy theorem to the particle to show that the total work done by the constant force after a time t is equal to the gain in kinetic energy of the particle.

Express the rate at which this force does work in terms of $\vec{F}$ and $\vec{v}$:

$$P = \vec{F} \cdot \vec{v} \qquad (1)$$

The velocity of the particle, in terms of its acceleration and the time that the force has acted is:

$$\vec{v} = \vec{a}t$$

Using Newton's second law, substitute for $\vec{a}$:

$$\vec{v} = \frac{\vec{F}}{m}t$$

Substitute for $\vec{v}$ in equation (1) and simplify to obtain:

$$P = \vec{F} \cdot \frac{\vec{F}}{m}t = \frac{\vec{F} \cdot \vec{F}}{m}t = \boxed{\frac{F^2}{m}t}$$

54 •• A 7.5-kg box is being lifted by means of a light rope that is threaded through a single, light, frictionless pulley that is attached to the ceiling. (*a*) If the box is being lifted at a *constant speed* of 2.0 m/s, what is the power delivered by the person pulling on the rope? (*b*) If the box is lifted, at *constant acceleration,* from rest on the floor to a height of 1.5 m above the floor in 0.42 s, what average power is delivered by the person pulling on the rope?

Picture the Problem Because, in (*a*), the box is being lifted at constant speed; the force acting on it is equal to the force due to gravity. We're given the speed and the force and thus calculation of the power is straightforward. In (*b*) we have a constant acceleration and are given the height to which the box is lifted and the time during which it is lifted. The work done in this case is the force times the displacement and the average power is the ratio of the work done to the time required. We can find the force acting on the box by applying Newton's second law and the acceleration of the box by using a constant-acceleration equation.

(*a*) The power exerted by the person pulling on the rope is given by:

$$P = \vec{T}\cdot\vec{v} = Tv\cos\theta$$

or, because $\vec{T}$ and $\vec{v}$ are in the same direction,

$$P = Tv \qquad (1)$$

Apply $\sum F_y = ma_y$ to the box to obtain:

$$T - F_g = ma_y$$

or, because $F_g = mg$ and $a_y = 0$,

$$T - mg = 0 \Rightarrow T = mg$$

Substituting for T in equation (1) yields:

$$P = mgv$$

Substitute numerical values and evaluate P:

$$P = (7.5\ \text{kg})(9.81\ \text{m/s}^2)(2.0\ \text{m/s}) = \boxed{0.15\ \text{kW}}$$

(*b*) The average power exerted by the person pulling the rope is given by:

$$P_{av} = \frac{\Delta W}{\Delta t} = \frac{F\Delta y}{\Delta t} \qquad (2)$$

Use a constant-acceleration equation to relate Δy to the interval of acceleration Δt:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or because the box starts from rest,

$$\Delta y = \tfrac{1}{2}a_y(\Delta t)^2 \Rightarrow a_y = \frac{2\Delta y}{(\Delta t)^2}$$

Apply $\sum F_y = ma_y$ to the box to obtain:

$$F = ma_y = m\frac{2\Delta y}{(\Delta t)^2}$$

Substitute for F in equation (2) to obtain:

$$P_{av} = \frac{m\dfrac{2\Delta y}{(\Delta t)^2}\Delta y}{\Delta t} = \frac{2m(\Delta y)^2}{(\Delta t)^3}$$

Substitute numerical values and evaluate P_{av}:

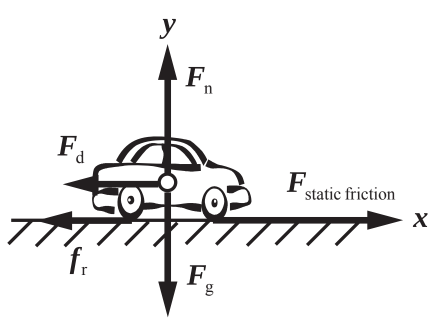
$$P_{av} = \frac{2(7.5\ \text{kg})(1.5\ \text{m})^2}{(0.42\ \text{s})^3} = \boxed{0.46\ \text{kW}}$$

Center of Mass Work and Center of Mass Translational Kinetic Energy

55 ••• You have been asked to test drive a car and study its actual performance relative to its specifications. This particular car's engine is rated at 164 hp. This value is the *peak* rating, which means that it is capable, at most, of providing energy at the rate of 164 hp to the drive wheels. You determine that the car's mass (including test equipment and driver on board) is 1220 kg. (*a*) When cruising at a constant 55.0 mi/h, your onboard engine-monitoring computer determines that the engine is producing 13.5 hp. From previous coasting experiments, it has been determined that the coefficient of rolling friction on the car is 0.0150. Assume that the drag force on the car varies as the square of the car's speed. That is, $F_d = Cv^2$. (*a*) What is the value of the constant, C? (*b*) Considering the peak power, what is the maximum speed (to the nearest 1 mi/h) that you would expect the car could attain? (This problem can be done by hand analytically, but it can be done more easily and quickly using a **graphing calculator** or **spreadsheet**.)

Comment: DAVID: In the solution the static frictional force of the road on the tires is referred to as the force exerted by the engine. This is not a good idea.

Picture the Problem When the car is moving at a constant speed, the static friction force exerted by the road on the tires must be balancing the force of rolling friction exerted by the roadway and the drag force exerted by the air. The power the engine produces is the product of this force and the velocity of the car.



(*a*) Apply $\sum F_x = ma_x$ to the car as it cruises at constant velocity:

$$F_{\substack{\text{static}\\\text{friction}}} - F_d - f = 0$$

Solve for $F_{\substack{\text{static}\\\text{friction}}}$ and substitute for F_d and f to obtain:

$$F_{\substack{\text{static}\\\text{friction}}} = Cv^2 + \mu_r F_g$$

or, because $F_n = F_g = mg$,

$$F_{\substack{\text{static}\\\text{friction}}} = Cv^2 + \mu_r mg$$

Multiplying both sides of this equation by the speed v of the car yields an expression for the power P developed by the engine:

$$F_{\substack{\text{static}\\\text{friction}}}\, v = P = \left(Cv^2 + \mu_{\text{r}} mg\right)v \quad (1)$$

Solve for C to obtain:

$$C = \frac{P}{v^3} - \frac{\mu_{\text{r}} mg}{v^2}$$

Express $P = 13.5$ hp in watts:

$$P = 13.5\ \text{hp} \times \frac{746\ \text{W}}{\text{hp}} = 10.07\ \text{kW}$$

Express $v = 55$ mi/h in m/s:

$$v = 55\,\frac{\text{mi}}{\text{h}} \times \frac{1609\ \text{m}}{1\ \text{mi}} \times \frac{1\ \text{h}}{3600\ \text{s}} = 24.58\ \text{m/s}$$

Substitute numerical values and evaluate C:

$$C = \frac{10.07\ \text{kW}}{(24.58\ \text{m/s})^3} - \frac{(0.0150)(1220\ \text{kg})(9.81\ \text{m/s}^2)}{(24.58\ \text{m/s})^2} = 0.3808\ \text{kg/m} = \boxed{0.381\ \text{kg/m}}$$

(*b*) Rewriting equation (1) with v as the variable yields the cubic equation:

$$v^3 + \frac{\mu_{\text{r}} mg}{C} v - \frac{P}{C} = 0$$

Express 164 hp in watts:

$$P = 164\ \text{hp} \times \frac{746\ \text{W}}{\text{hp}} = 122.3\ \text{kW}$$

Substitute numerical values in the cubic equation and simplify to obtain:

$$v^3 + \frac{(0.015)(1220\ \text{kg})(9.81\ \text{m/s}^2)}{0.3808\ \text{kg/m}} v - \frac{122.3\ \text{kW}}{0.3808\ \text{kg/m}} = 0$$

or

$$v^3 + \left(471.4\ \text{m}^2/\text{s}^2\right)v - 3.213\times 10^5\ \text{m}^3/\text{s}^3 = 0$$

Use your graphing calculator to solve this cubic equation and then use conversion factors from your text to convert your answer to mi/h:

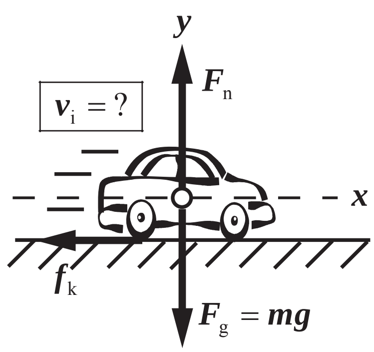
$$v = 66.20\,\frac{\text{m}}{\text{s}} \times \frac{0.6818\,\frac{\text{mi}}{\text{h}}}{0.3048\,\frac{\text{m}}{\text{s}}} = \boxed{148\ \text{mi/h}}$$

56 •• As you drive your car along a country road at night, a deer jumps out of the woods and stands in the middle of the road ahead of you. This occurs just as you are passing from a 55-mi/h zone to a 50-mi/h zone. At the 50-mi/h speed-

limit sign, you slam on the car's brakes, causing them to lock up, and skid to a stop inches from the startled deer. As you breathe a sigh of relief, you hear the sound of a police siren. The policeman proceeds to write you a ticket for driving 56 mi/h in 50-mi/h zone. Because of your preparation in physics, you are able to use the 25-m-long skid marks that your car left behind as evidence that you were not speeding. What evidence do you present? In formulating your answer, you will need to know the coefficient of kinetic friction between automobile tires and dry concrete (see Table 5-1).

Comment: DAVID: Your solution needs to refer to the table value. In addition, you need to change static to kinetic near the end of the solution

Picture the Problem We can apply the work-kinetic energy theorem to the car as it slides to a halt to relate the work done by kinetic friction to its initial speed v_i. Because the sum of the forces acting on the car in the y direction is zero, we can use the definition of the coefficient of kinetic friction to express the kinetic friction force $\vec{f}_k$ in terms of the gravitational force $\vec{F}_g = m\vec{g}$.



Apply the work-kinetic energy theorem to your car to obtain:

$$W_{total} = \Delta K = K_f - K_i$$

or, because $K_f = 0$,

$$W_{total} = -K_i \qquad (1)$$

The total work done on your car is done by the kinetic friction force that brings your car to a stop:

$$W_{total} = W_{by\ friction} = \vec{f}_k \cdot \vec{d} = f_k d \cos\theta$$

or, because $\vec{f}_k$ and $\vec{d}$ are in opposite directions ($\theta = 180°$),

$$W_{total} = -f_k d$$

Substituting for K_i and W_{total} in equation (1) yields:

$$-f_k d = -\tfrac{1}{2} m v_i^2$$

or, because $f_k = \mu_k F_n$,

$$\mu_k F_n d = \tfrac{1}{2} m v_i^2 \qquad (2)$$

Apply $\sum F_y = ma_y$ to your car to obtain:

$$F_n - F_g = 0 \Rightarrow F_n = F_g = mg$$

Substituting for F_n in equation (2) yields:

$$\mu_k mgd = \tfrac{1}{2} m v_i^2 \Rightarrow v_i = \sqrt{2\mu_k g d}$$

Referring to Table 5-1 for the coefficient of kinetic friction for rubber on dry concrete, substitute numerical values and evaluate v_i:

$$v_i = \sqrt{2(0.80)(9.81\ \text{m/s}^2)(25\ \text{m})} = 19.81\ \text{m/s}$$

Convert v_i to mi/h to obtain:

$$v = 19.81\frac{\text{m}}{\text{s}} \times \frac{0.6818\,\frac{\text{mi}}{\text{h}}}{0.3048\,\frac{\text{m}}{\text{s}}} = 44\ \text{mi/h}$$

Thus, at the time you applied your brakes, which occurred as you passed the 50 mi/h sign, you were doing 6 mi/h under the limit. Your explanation should convince the judge to void the ticket.

General Problems

57 • In February 2002, a total of 60.7 billion kW·h of electrical energy was generated by nuclear power plants in the United States. At that time, the population of the United States was about 287 million people. If the average American has a mass of 60 kg, and if 25% of the entire energy output of all nuclear power plants was diverted to supplying energy for a single giant elevator, estimate the height h to which the entire population of the country could be lifted by the elevator. In your calculations, assume that g is constant over the entire height h.

Picture the Problem 25 % of the electrical energy generated is to be diverted to do the work required to change the potential energy of the American people. We can calculate the height to which they can be lifted by equating the change in potential energy to the available energy.

Express the change in potential energy of the population of the United States in this process:

$$\Delta U = Nmgh$$

Letting E represent the total energy generated in February 2002, relate the change in potential to the energy available to operate the elevator:

$$Nmgh = 0.25E \Rightarrow h = \frac{0.25E}{Nmg}$$

Substitute numerical values and evaluate *h*:

$$h=\frac{(0.25)\left(60.7\times10^{9}\,\text{kW}\cdot\text{h}\right)\left(\dfrac{3600\,\text{s}}{1\,\text{h}}\right)}{\left(287\times10^{6}\right)(60\,\text{kg})\left(9.81\,\text{m/s}^{2}\right)}=\boxed{3.2\times10^{5}\,\text{m}}$$

58 • One of the most powerful cranes in the world operates in Switzerland. It can slowly raise a 6000-t load to a height of 12.0 m. (Note that 1 t = one tonne is sometimes called a metric ton. It is a unit of mass, not force, and is equal to 1000 kg.) (*a*) How much work is done by the crane during this lift? (*b*) If it takes 1.00 min to lift this load to this height at constant velocity, and the crane is 20 percent efficient, find the total (gross) power rating of the crane.

Picture the Problem We can use the definition of the work to find the work done by the crane in lifting this load and the definition of power to find the total power rating of the crane.

(*a*) The work done by the crane in lifting the load from position 1 to position 2 is given by:

$$W_{\text{by crane}}=\int_1^2\vec{\boldsymbol{F}}\cdot d\vec{\boldsymbol{s}}$$

where $\vec{\boldsymbol{F}}$ is the force exerted by the crane.

Because $\vec{\boldsymbol{F}}$ and $d\vec{\boldsymbol{s}}$ are in the same direction:

$$W_{\text{by crane}}=\int_1^2 F\,ds=F(s_2-s_1)=Fh$$

or, because $F=F_{\text{g}}=mg$,

$$W_{\text{by crane}}=mgh$$

Substitute numerical values and evaluate $W_{\text{by crane}}$:

$$W_{\text{by crane}}=\left(6.000\times10^{6}\,\text{kg}\right)\left(9.81\,\text{m/s}^{2}\right)(12.0\,\text{m})=706.3\,\text{MJ}=\boxed{706\,\text{MJ}}$$

(*b*) If the efficiency of the crane is η, the total power rating of the crane is given by:

$$P_{\text{total}}=\frac{\Delta W}{\eta(\Delta t)}$$

where ΔW is the work we calculated in part (*a*).

Substitute numerical values and evaluate P_{total}:

$$P_{\text{total}}=\frac{706.3\,\text{MJ}}{(0.20)(60.0\,\text{s})}=\boxed{59\,\text{MW}}$$

59 • In Austria, there once was a 5.6-km-long ski lift. It took about 60 min for a gondola to travel up its length. If there were 12 gondolas going up, each with a cargo of mass 550 kg, and if there were 12 empty gondolas going down, and the angle of ascent was 30º, estimate the power *P* the engine needed to deliver in order to operate the ski lift.

Picture the Problem The power *P* of the engine needed to operate this ski lift is equal to the rate at which it does work on the gondolas. Because as many empty gondolas are descending as are ascending, we do not need to know their mass.

Express the rate at which work is done as the cars are lifted:

$$P_{av} = \frac{\Delta W}{\Delta t} = \frac{F\Delta s}{\Delta t}$$

where *F* is the force exerted by the engine on the gondola cars and Δs is the vertical displacement of the cars.

For *N* gondola cars, each of mass *M*, $F = F_g = NMg$:

$$P_{av} = \frac{NMg\Delta s}{\Delta t}$$

Relate Δs to the angle of ascent θ and the length *L* of the ski lift:

$$\Delta s = L\sin\theta$$

Substituting for Δs yields:

$$P_{av} = \frac{NMgL\sin\theta}{\Delta t}$$

Substitute numerical values and evaluate *P*:

$$P = \frac{12(550\,\text{kg})(9.81\,\text{m/s}^2)(5.6\,\text{km})\sin 30°}{(60\,\text{min})(60\,\text{s/min})} = \boxed{50\,\text{kW}}$$

60 •• To complete your master's degree in physics, your advisor has you design a small linear accelerator capable of emitting protons, each with a kinetic energy of 10.0 keV. (The mass of a single proton is 1.67×10^{-27} kg.) In addition, 1.00×10^{9} protons per second must reach the target at the end of the 1.50-m-long accelerator. (*a*) What average power must be delivered to the stream of protons? (*b*) What force (assumed constant) must be applied to each proton? (*c*) What speed does each proton attain just before it strikes the target, assuming the protons start from rest?

Picture the Problem We can use the definition of average power and the work-kinetic energy theorem to find the average power delivered to the target. A second application of the work-kinetic energy theorem and the use of the definition of

work will yield the force exerted on each proton. Finally, we can use the definition of kinetic energy to find the speed of each proton just before it hits the target.

(*a*) The average power delivered by the stream of protons is given by:

$$P_{\text{av}} = \frac{\Delta W}{\Delta t} \quad (1)$$

Apply the work-kinetic energy theorem to the proton beam to obtain:

$$W_{\text{total}} = \Delta K$$

Substituting ΔK for ΔW in equation (1) yields:

$$P_{\text{av}} = \frac{\Delta K}{\Delta t}$$

Substitute numerical values and evaluate P_{av}:

$$P_{\text{av}} = \frac{10.0\ \text{keV/particle}}{1.00\times10^{-9}\ \text{s/particle}} \times \frac{1.602\times10^{-19}\ \text{J}}{\text{eV}} = 1.602\times10^{-6}\ \text{W} = \boxed{1.60\ \mu\text{W}}$$

(*b*) Apply the work-kinetic energy theorem to a proton to obtain:

$$W_{\text{total}} = \Delta K \quad (2)$$

The work done by the accelerating force $\vec{F}$ on each proton is:

$$W_{\text{total}} = \vec{F}\cdot\vec{d} = Fd\cos\theta$$

or, because $\vec{F}$ and $\vec{d}$ are in the same direction,

$$W_{\text{total}} = Fd$$

Substituting for W_{total} in equation (2) yields:

$$Fd = \Delta K \Rightarrow F = \frac{\Delta K}{d}$$

Substitute numerical values and evaluate F:

$$F = \frac{10.0\ \text{keV}\times\dfrac{1.602\times10^{-19}\ \text{J}}{\text{eV}}}{1.50\ \text{m}} = 1.068\times10^{-15}\ \text{N} = \boxed{1.07\ \text{fN}}$$

(*c*) The kinetic energy of each proton is related to its speed:

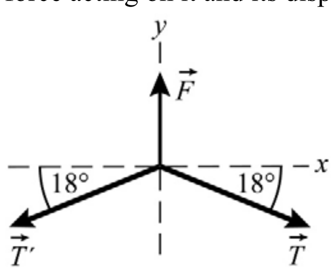
$$K_{\text{f}} = \tfrac{1}{2}mv_{\text{f}}^2 \Rightarrow v_{\text{f}} = \sqrt{\frac{2K_{\text{f}}}{m}}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{\frac{2\left(10.0\,\text{keV} \times \frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}\right)}{1.67\times10^{-27}\ \text{kg}}} = \boxed{1.39\times10^{6}\ \text{m/s}}$$

61 ••• The four strings pass over the bridge of a violin, as shown in Figure 6-35. The strings make an angle of 72.0° with the normal to the plane of the instrument on either side of the bridge. The resulting total normal force pressing the bridge into the violin is 1.00×10^3 N. The length of the strings from the bridge to the peg to which each is attached is 32.6 cm. (*a*) Determine the tension in the strings, assuming the tension is the same for each string. (*b*) One of the strings is plucked out a distance of 4.00 mm, as shown. Make a free-body diagram showing all of the forces acting on the segment of the string in contact with the finger (not shown), and determine the force pulling the segment back to its equilibrium position. Assume the tension in the string remains constant during the pluck. (*c*) Determine the work done on the string in plucking it out that distance. Remember that the net force pulling the string back to its equilibrium position is changing as the string is being pulled out, but assume that the magnitudes of the tension forces remain constant.

Picture the Problem The free-body diagram shows the forces acting on one of the strings at the bridge. The force whose magnitude is F is one-fourth of the force (1.00×10^3 N) the bridge exerts on the strings. We can apply the condition for equilibrium in the y direction to find the tension in each string. Repeating this procedure at the site of the plucking will yield the restoring force acting on the string. We can find the work done on the string as it returns to equilibrium from the product of the average force acting on it and its displacement.



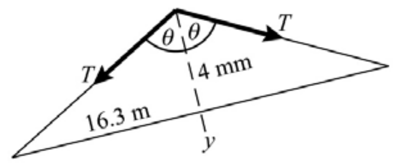
(*a*) Noting that, due to symmetry $T' = T$, apply $\sum F_y = 0$ to the string at the point of contact with the bridge:

$$F - 2T\sin 18.0° = 0 \Rightarrow T = \frac{F}{2\sin 18.0°}$$

Substitute numerical values and evaluate T:

$$T = \frac{\frac{1}{4}\left(1.00\times10^{3}\ \text{N}\right)}{2\sin18.0°} = 404.51\ \text{N}$$
$$= \boxed{405\ \text{N}}$$

(b) A free-body diagram showing the forces restoring the string to its equilibrium position just after it has been plucked is shown to the right:



Express the net force acting on the string immediately after it is released:

$$F_{\text{net}} = 2T\cos\theta \qquad (1)$$

Use trigonometry to find θ:

$$\theta = \tan^{-1}\left(\frac{16.3\,\text{cm}}{4.00\,\text{mm}}\times\frac{10\,\text{mm}}{\text{cm}}\right) = 88.594°$$

Substitute numerical values for T and θ in equation (1) and evaluate F_{net}:

$$F_{\text{net}} = 2(404.51\,\text{N})\cos88.594°$$
$$= 19.851\text{N} = \boxed{19.9\,\text{N}}$$

(c) Express the work done on the string in displacing it a distance dx':

$$dW = Fdx'$$

If we pull the string out a distance x', the magnitude of the force pulling it down is approximately:

$$F = (2T)\frac{x'}{L/2} = \frac{4T}{L}x'$$

Substitute to obtain:

$$dW = \frac{4T}{L}x'\,dx'$$

Integrate dW to obtain:

$$W = \frac{4T}{L}\int_0^x x'dx' = \frac{2T}{L}x^2$$

where x is the final displacement of the string.

Substitute numerical values and evaluate W:

$$W = \frac{2(404.51\,\text{N})}{32.6\times10^{-2}\ \text{m}}\left(4.00\times10^{-3}\ \text{m}\right)^2$$
$$= \boxed{39.7\,\text{mJ}}$$

62 •• The magnitude of the single force acting on a particle of mass m is given by $F = bx^2$, where b is a constant. The particle starts from rest. After it travels a distance L, determine its (a) kinetic energy and (b) speed.

Comment: DAVID: F_x was changed to F, and a was changed to b.

Picture the Problem We can apply the work-kinetic energy theorem and the definition of work to the particle to find its kinetic energy when it has traveled a distance L. We can then use the definition of kinetic energy to find its speed at this location.

(a) Apply the work-kinetic energy theorem to the particle to obtain:

$$W_{\text{total}} = \Delta K = K_{\text{f}} - K_{\text{i}}$$

or, because the particle is initially at rest,

$$W_{\text{total}} = K_{\text{f}} = \tfrac{1}{2}mv_{\text{f}}^2 \qquad (1)$$

The total work done on the particle is also given by:

$$dW_{\text{total}} = \vec{F}\cdot d\vec{x} = Fdx\cos\theta$$

or, because $\vec{F}$ and $d\vec{x}$ are in the same direction,

$$dW_{\text{total}} = K_{\text{f}} = Fdx$$

Substituting for F_x and going from differential to integral form yields:

$$K_{\text{f}} = \int_0^L bx^2dx = b\int_0^L x^2dx = \boxed{\tfrac{1}{3}bL^3}$$

(b) Substitute for K_{f} in equation (1) to obtain:

$$\tfrac{1}{3}bL^3 = \tfrac{1}{2}mv_{\text{f}}^2 \Rightarrow v_{\text{f}} = \boxed{\sqrt{\frac{2bL^3}{3m}}}$$

63 •• **[SSM]** A single horizontal force in the $+x$ direction acts on a cart of mass m. The cart starts from rest at $x = 0$, and the speed of the cart increases with x as $v = Cx$, where C is a constant. (a) Find the force acting on the cart as a function of x. (b) Find the work done by the force in moving the cart from $x = 0$ to $x = x_1$.

Picture the Problem We can use the definition of work to obtain an expression for the position-dependent force acting on the cart. The work done on the cart can be calculated from its change in kinetic energy.

(a) Express the force acting on the cart in terms of the work done on it:

$$F(x) = \frac{dW}{dx} \qquad (1)$$

Apply the work-kinetic energy theorem to the cart to obtain:

$$W = \Delta K = K - K_{\text{i}}$$

or, because the cart starts from rest,

$$W = K$$

Substitute for W in equation (1) to obtain:

$$F(x)=\frac{dK}{dx}=\frac{d}{dx}\left(\tfrac{1}{2}mv^2\right)=\frac{d}{dx}\left[\tfrac{1}{2}m(Cx)^2\right]=\boxed{mC^2x}$$

(*b*) The work done by this force changes the kinetic energy of the cart:

$$W=\Delta K=\tfrac{1}{2}mv_1^2-\tfrac{1}{2}mv_0^2=\tfrac{1}{2}mv_1^2-0=\tfrac{1}{2}m(Cx_1)^2=\boxed{\tfrac{1}{2}mC^2x_1^2}$$

64 •• A force $\vec{F}=\left(2.0\ \text{N/m}^2\right)x^2\hat{i}$ is applied to a particle initially at rest in the *xy* plane. Find the work done by this force on the particle, and its final speed, as it moves along a path that is (*a*) in a straight line from point (2.0 m, 2.0 m) to point (2.0 m, 7.0 m), and (*b*) in a straight line from point (2.0 m, 2.0 m) to point (5.0 m, 6.0 m). (The given force is the only force doing work on the particle.)

Picture the Problem The work done by $\vec{\boldsymbol{F}}$ on the particle depends on whether $\vec{\boldsymbol{F}}$ causes a displacement of the particle in the direction it acts. We can apply the work-kinetic energy theorem to find the final speed of the particle in each case.

(*a*) The work done on the particle is given by:

$$W=\int\vec{\boldsymbol{F}}\cdot d\vec{\ell}$$

Substitute for $\vec{\boldsymbol{F}}$ and $\boldsymbol{d}\vec{\ell}$ to obtain:

$$W=\int_{2.0\,\text{m}}^{7.0\,\text{m}}\left(2.0\ \text{N/m}^2\right)x^2\,\hat{\boldsymbol{i}}\cdot dx\,\hat{\boldsymbol{j}}=\boxed{0}$$

Apply the work-kinetic energy theorem to the particle to obtain:

$$W=\Delta K=K_\text{f}-K_\text{i}$$

or, because the particle starts from rest and $W=0$,

$$K_\text{f}=0\Rightarrow v_\text{f}=\boxed{0}$$

(*b*) Calculate the work done by $\vec{F}$ during the displacement of the particle from $x = 2.0$ m to 5.0 m:

$$W = \int_{2.0\,\text{m}}^{5.0\,\text{m}} \left(\left(2.0\,\text{N/m}^2\right)x^2\right)\hat{\boldsymbol{i}} \cdot dx\,\hat{\boldsymbol{i}}$$

$$= \left(2.0\,\text{N/m}^2\right)\int_{2.0\,\text{m}}^{5.0\,\text{m}} x^2\,dx$$

$$= \left(2.0\,\text{N/m}^2\right)\left[\frac{x^3}{3}\right]_{2.0\,\text{m}}^{5.0\,\text{m}}$$

$$= \boxed{78\,\text{J}}$$

Apply the work-kinetic energy theorem to the particle to obtain:

$$W = \Delta K = K_\text{f} - K_\text{i}$$

or, because the particle starts from rest,

$$K_\text{f} = 78\text{ J} \Rightarrow v_\text{f} = \sqrt{\frac{2(78\text{ J})}{m}} = \boxed{\frac{156\text{ J}}{m}}$$

where m is the mass of the particle.

65 •• A particle of mass m moves along the x axis. Its position varies with time according to $x = 2t^3 - 4t^2$, where x is in meters and t is in seconds. Find (*a*) the velocity and acceleration of the particle as functions of t, (*b*) the power delivered to the particle as a function of t, and (*c*) the work done by the net force from $t = 0$ to $t = t_1$.

Picture the Problem The velocity and acceleration of the particle can be found by differentiation. The power delivered to the particle can be expressed as the product of its velocity and the net force acting on it, and the work done by the force and can be found from the change in kinetic energy this work causes.

In the following, if t is in seconds and m is in kilograms, then v is in m/s, a is in m/s^2, P is in W, and W is in J.

(*a*) The velocity of the particle is given by:

$$v = \frac{dx}{dt} = \frac{d}{dt}\left(2t^3 - 4t^2\right) = \boxed{\left(6t^2 - 8t\right)}$$

The acceleration of the particle is given by:

$$a = \frac{dv}{dt} = \frac{d}{dt}\left(6t^2 - 8t\right) = \boxed{(12t - 8)}$$

(*b*) Express the rate at which energy is delivered to this particle as it accelerates:

$$P = Fv = mav$$

Substitute for a and v and simplify to obtain:

$$P = m(12t - 8)(6t^2 - 8t) = \boxed{8mt(9t^2 - 18t + 8)}$$

(c) Apply the work-kinetic energy theorem to the particle to obtain:

$$W = \Delta K = K_1 - K_0$$

Substitute for K_1 and K_0 and simplify:

$$W = \tfrac{1}{2}m\left[(v(t_1))^2 - (v(0))^2\right] = \tfrac{1}{2}m\left[(6t_1^2 - 8t_1)\right]^2 - 0 = \boxed{2mt_1^2(3t_1 - 4)^2}$$

Remarks: We could also find *W* by integrating *P*(*t*) with respect to time.

66 •• A 3.0-kg particle starts from rest at x = 0.050 m and moves along the x axis under the influence of a single force $F_x = 6.0 + 4.0x - 3.0x^2$, where F_x is in newtons and x is in meters. (a) Find the work done by the force as the particle moves from x = 0.050 m to x = 3.0 m. (b) Find the power delivered to the particle as it passes through the point x = 3.0 m.

Comment: DAVID: The initial position has been changed.

Picture the Problem We can calculate the work done by the given force from its definition. The power can be determined from $P = \vec{F}\cdot\vec{v}$ and v from the change in kinetic energy of the particle produced by the work done on it.

(a) Express the work done on the particle:

$$W = \int \vec{F}_x \cdot d\vec{s} = \int F_x\hat{i}\cdot ds\,\hat{i} = \int F_x ds$$

Substitute for F_x and ds and evaluate the definite integral:

$$W = \int_{0.50\text{ m}}^{3.0\text{ m}} (6.0 + 4.0x - 3.0x^2)dx = \left[6.0x + \frac{4.0x^2}{2} - \frac{3.0x^3}{3}\right]_{0.50\text{ m}}^{3.0\text{ m}} = 5.625\text{ J} = \boxed{5.6\text{ J}}$$

(b) Express the power delivered to the particle as it passes through the point at x = 3.0 m:

$$P = \vec{F}\cdot\vec{v} = F_{x=3.0\text{ m}}v_{x=3.0\text{ m}} \qquad (1)$$

Apply the work-kinetic energy theorem to find the work done on the particle as it moves from the point at x = 0.050 m to the point at x = 3.0 m:

$$W = \Delta K = K_{x=3.0\text{ m}} - K_{x=0.050\text{ m}}$$

or, because $K_{x=0.050\text{ m}} = 0$,

$$W = K_{x=3.0\text{ m}} = \tfrac{1}{2}mv_{x=3.0\text{ m}}^2$$

Solving for $v_{x=3.0\,\text{m}}$ gives:

$$v_{x=3.0\,\text{m}} = \sqrt{\frac{2W}{m}}$$

Substituting for $v_{x\,=\,3.0\,\text{m}}$ and $F_{x\,=\,3.0\,\text{m}}$ in equation (1) yields:

$$P_{x=3.0\,\text{m}} = \left(6.0 + 4.0x - 3.0x^2\right)_{x=3.0\,\text{m}} \sqrt{\frac{2W_{x=3.0\,\text{m}}}{m}}$$

Substitute numerical values and evaluate $P_{x\,=\,3.0\,\text{m}}$:

$$P_{x=3.0\,\text{m}} = \left[6.0 + 4.0(3.0\,\text{m}) - 3.0(3.0\,\text{m})^2\right]\sqrt{\frac{2(5.625\,\text{J})}{3.0\,\text{kg}}} = \boxed{-17\,\text{W}}$$

67 •• The initial kinetic energy imparted to a 0.0200-kg bullet is 1200 J. (*a*) Assuming it accelerated down a 1.00-m-long rifle barrel, estimate the average power delivered to it during the firing. (*b*) Neglecting air resistance, find the range of this projectile when it is fired at an angle such that the range equals the maximum height attained.

Picture the Problem We'll assume that the firing height is negligible and that the bullet lands at the same elevation from which it was fired. We can use the equation $R = \left(v_0^2/g\right)\sin 2\theta$ to find the range of the bullet and constant-acceleration equations to find its maximum height. The bullet's initial speed can be determined from its initial kinetic energy.

(*a*) The average power delivered to the bullet during firing is given by:

$$P_{\text{av}} = \frac{\Delta W}{\Delta t} \qquad (1)$$

Apply the work-kinetic energy theorem to the bullet to obtain:

$$W_{\text{total}} = \Delta K = K_{\text{f}} - K_{\text{i}}$$

or, because the initial speed of the bullet is zero,

$$W_{\text{total}} = K_{\text{f}} = \tfrac{1}{2}mv_{\text{f}}^2 \Rightarrow v_{\text{f}} = \sqrt{\frac{2K_{\text{f}}}{m}}$$

Because the acceleration of the bullet is (assumed to be) constant, its average speed in the barrel is:

$$v_{\text{av}} = \frac{v_{\text{i}} + v_{\text{f}}}{2} = \tfrac{1}{2}v_{\text{f}}$$

The time-in-the-barrel is given by:

$$\Delta t = \frac{\ell}{v_{\text{av}}} = \frac{2\ell}{v_{\text{f}}} = \frac{2\ell}{\sqrt{\dfrac{2K_{\text{f}}}{m}}}$$

Substituting for Δt in equation (1) and simplifying yields:

$$P_{\text{av}} = \frac{K_{\text{f}}}{2\ell}\sqrt{\frac{2K_{\text{f}}}{m}}$$

Substitute numerical values and evaluate P_{av}:

$$P_{\text{av}} = \frac{1200\ \text{J}}{2(1.00\ \text{m})}\sqrt{\frac{2(1200\ \text{J})}{0.0200\ \text{kg}}} = \boxed{208\ \text{kW}}$$

(*b*) Using the ″equal-height″ range equation, express the range of the bullet as a function of its firing speed and angle of firing:

$$R = \frac{v_0^2}{g}\sin 2\theta$$

Rewrite the range equation using the trigonometric identity $\sin 2\theta = 2\sin\theta\cos\theta$:

$$R = \frac{v_0^2 \sin 2\theta}{g} = \frac{2v_0^2 \sin\theta\cos\theta}{g} \quad (2)$$

Using constant-acceleration equations, express the position coordinates of the projectile along its flight path in terms of the parameter *t*:

$$x = (v_0\cos\theta)t$$

and

$$y = (v_0\sin\theta)t - \tfrac{1}{2}gt^2$$

Eliminate the parameter *t* and make use of the fact that the maximum height occurs when the projectile is at half the range to obtain:

$$h = \frac{(v_0\sin\theta)^2}{2g}$$

Equate *R* and *h* to obtain:

$$\frac{(v_0\sin\theta)^2}{2g} = \frac{2v_0^2\sin\theta\cos\theta}{g}$$

Simplifying this equation yields:

$$\tan\theta = 4 \Rightarrow \theta = \tan^{-1}(4) = 76.0°$$

Relate the bullet's kinetic energy to its mass and speed and solve for the square of its speed:

$$K = \tfrac{1}{2}mv_0^2 \Rightarrow v_0^2 = \frac{2K}{m}$$

Substitute for v_0^2 in equation (2) to obtain:

$$R = \frac{2K\sin 2\theta}{mg}$$

Substitute numerical values and evaluate *R*:

$$R = \frac{2(1200\ \text{J})\sin[2(76.0°)]}{(0.0200\ \text{kg})(9.81\ \text{m/s}^2)} = \boxed{5.74\ \text{km}}$$

68 •• The force F_x acting on a 0.500-kg particle is shown as a function of x in Figure 6-36. (*a*) From the graph, calculate the work done by the force when the particle moves from x = 0.00 to the following values of x: –4.00, –3.00, –2.00, –1.00, +1.00, +2.00, +3.00, and +4.00 m. (*b*) If it starts with a velocity of 2.00 m/s in the +x direction, how far will the particle go in that direction before stopping?

Picture the Problem The work done on the particle is the area under the force-versus-displacement curve. Note that for negative displacements, F is positive, so W is negative for $x < 0$.

(*a*) Use either the formulas for the areas of simple geometric figures *or* counting squares and multiplying by the work represented by one square (each square is 1.00 J) to complete the following table:

x, m	–4.00	–3.00	–2.00	–1.00	1.00	2.00	3.00	4.00
W, J	–11	–10	–7.0	–3.0	1.0	0	–2.0	–3.0

(*b*) The energy that the particle must lose before it stops is its kinetic energy at $x = 0$:

$$K_{x=0} = \tfrac{1}{2} m v_{x=0}^2$$

Substitute numerical values and evaluate $K_{x=0}$:

$$K_{x=0} = \tfrac{1}{2}(0.500\text{ kg})(2.00\text{ m/s})^2 = 1.00\text{ J}$$

The particle is accelerated (recall that $F_x = -dU/dx$) between $x = 0$ and $x = 1.00$ m and gains an additional 1.00 J of kinetic energy. When it arrives at $x = 2.00$ m, however, it will have lost the kinetic energy it gained between $x = 0$ and $x = 1.00$ m and its kinetic energy will again be 1.00 J. Inspection of the graph leads us to conclude that it will have lost its remaining kinetic energy when it reaches $x = \boxed{2.50\text{ m.}}$

69 •• (*a*) Repeat Problem 68(*a*) for the force F_x shown in Figure 6-37. (*b*) If the object starts at the origin moving to the right with a kinetic energy of 25.0 J, how much kinetic energy does it have at x = 4.00 m.

Picture the Problem The work done on the particle is the area under the force-versus-displacement curve. Note that for negative displacements, F is negative, so W is positive for $x < 0$. In (*b*), we can apply the work-kinetic energy theorem to find the kinetic energy at x = 4.0 m.

(*a*) Use either the formulas for the areas of simple geometric figures *or* counting squares and multiplying by the work represented by one square (each square is 1.00 J) to complete the following table:

x, m	–4.00	–3.00	–2.00	–1.00	0	1.00	2.00	3.00	4.00
W, J	6	4	2	0.5	0	0.5	1.5	2.5	3.0

(*b*) Apply the work-kinetic energy theorem to the particle to obtain:

$$W_{\text{total}} = \Delta K = K_{x=4\,\text{m}} - K_{x=0}$$

Solving for $K_{x=4\,\text{m}}$ yields:

$$K_{x=4\,\text{m}} = W_{\text{total}} + K_{x=0} = W_{\text{total}} + 25.0\ \text{J}$$

From $x = 0$ to $x = 4$ m, the total work done by the force is:

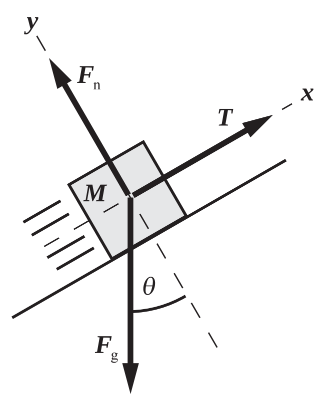
$$W_{\text{total}} = 3\ \text{square} \times \frac{1.00\ \text{J}}{\text{square}} = 3.00\ \text{J}$$

Substitute for W_{total} in the expression for $K_{x=4\,\text{m}}$ to obtain:

$$K_{x=4\,\text{m}} = 3.00\ \text{J} + 25.0\ \text{J} = \boxed{28.0\ \text{J}}$$

70 •• A box of mass M is at rest at the bottom of a frictionless inclined plane (Figure 6-38). The box is attached to a string that pulls with a constant tension T. (*a*) Find the work done by the tension T as the box moves through a distance x along the plane. (*b*) Find the speed of the box as a function of x. (*c*) Determine the power delivered by the tension in the string as a function of x.

Picture the Problem The forces acting on the block are shown in the free-body diagram. We can use the definition of work to find the work done by $\vec{T}$ in displacing the block a distance x up the incline and the work-kinetic energy theorem to express the speed of the box as a function of x and θ. Finally, we can use the definition of power to determine the power produced by the tension in terms of x and θ.



(*a*) Use the definition of work to express the work the tension *T* does moving the box a distance *x* up the incline:

$$W=\int_0^x \vec{\boldsymbol{T}}\cdot d\vec{\mathbf{x}}=\int_0^x T\,dx\cos\phi$$

or, because the angle between $\vec{\boldsymbol{T}}$ and $d\vec{\mathbf{x}}$ is zero,

$$W=T\int_0^x dx$$

Evaluate this integral to obtain:

$$W_{\text{by }T}=\boxed{Tx}$$

(*b*) Apply the work-kinetic energy theorem to the box to obtain:

$$W_{\text{total}}=\Delta K=K_{\text{f}}-K_{\text{i}}$$

or, because the box is initially at rest,

$$W_{\text{total}}=K_{\text{f}}=\tfrac{1}{2}Mv_{\text{f}}^2\Rightarrow v_{\text{f}}=\sqrt{\frac{2W_{\text{total}}}{M}}$$

The total work done on the box is the work done by the net force acting on it:

$$W_{\text{total}}=\int_0^x \vec{\boldsymbol{F}}_{\text{net}}\cdot d\vec{\mathbf{x}}=\int_0^x F_{\text{net}}\,dx\cos\phi$$

or, because the angle between $\vec{F}_{\text{net}}$ and $d\vec{x}$ is zero, $W_{\text{total}}=\int_0^x F_{\text{net}}\,dx$

Referring to the force diagram, we see that the net force acting on the block is:

$$F_{\text{net}}=T-Mg\sin\theta$$

Substitute for F_{net} and evaluate the integral to obtain:

$$W_{\text{total}}=\int_0^x (T-Mg\sin\theta)dx=(T-Mg\sin\theta)x$$

Substituting for W_{total} in the expression for v_{f} and simplifying yields:

$$v_{\text{f}}=\sqrt{\frac{2(T-Mg\sin\theta)x}{M}}=\boxed{\sqrt{2\left(\frac{T}{M}-g\sin\theta\right)x}}$$

(c) The power produced by the tension in the string is given by:

$$P=\vec{\boldsymbol{T}}\cdot\vec{\boldsymbol{v}}_{\text{f}}=Tv_{\text{f}}\cos\phi$$

or, because the angle between $\vec{\boldsymbol{T}}$ and $\vec{\boldsymbol{v}}_{\text{f}}$ is zero, $P=Tv_{\text{f}}$

Substitute for v_f to obtain:

$$P = \boxed{T\sqrt{2\left(\frac{T}{M} - g\sin\theta\right)x}}$$

71 ••• [SSM] A force acting on a particle in the *xy* plane at coordinates (*x*, *y*) is given by $\vec{F} = (F_0/r)(y\hat{i} - x\hat{j})$, where F_0 is a positive constant and *r* is the distance of the particle from the origin. (*a*) Show that the magnitude of this force is F_0 and that its direction is perpendicular to $\vec{r} = x\hat{i} + y\hat{j}$. (*b*) Find the work done by this force on a particle that moves once around a circle of radius 5.0 m that is centered at the origin.

Picture the Problem (*a*) We can use the definition of the magnitude of vector to show that the magnitude of $\vec{F}$ is F_0 and the definition of the scalar product to show that its direction is perpendicular to $\vec{r}$. (*b*) The work done as the particle moves in a circular path can be found from its definition.

(*a*) Express the magnitude of $\vec{F}$:

$$\left|\vec{F}\right| = \sqrt{F_x^2 + F_y^2} = \sqrt{\left(\frac{F_0}{r}y\right)^2 + \left(-\frac{F_0}{r}x\right)^2} = \frac{F_0}{r}\sqrt{x^2 + y^2}$$

Because $r = \sqrt{x^2 + y^2}$:

$$\left|\vec{F}\right| = \frac{F_0}{r}\sqrt{x^2 + y^2} = \frac{F_0}{r}r = \boxed{F_0}$$

Form the scalar product of $\vec{F}$ and $\vec{r}$:

$$\vec{F}\cdot\vec{r} = \left(\frac{F_0}{r}\right)\left(y\,\hat{i} - x\,\hat{j}\right)\cdot\left(x\,\hat{i} + y\,\hat{j}\right) = \left(\frac{F_0}{r}\right)(xy - xy) = 0$$

Because $\vec{F}\cdot\vec{r} = 0$:

$$\boxed{\vec{F} \perp \vec{r}}$$

(*b*) The work done in an angular displacement from θ_1 to θ_2 is given by:

$$W_{1\,\text{rev}} = \int_{\theta_1}^{\theta_2} \vec{F}\cdot d\vec{s} = \int_{\theta_1}^{\theta_2}\left(\frac{F_0}{r}\right)\left(y\,\hat{i} - x\,\hat{j}\right)\cdot d\vec{s} = \frac{F_0}{r}\int_{\theta_1}^{\theta_2}\left(r\sin\theta\,\hat{i} - r\cos\theta\,\hat{j}\right)\cdot d\vec{s} = F_0\int_{\theta_1}^{\theta_2}\left(\sin\theta\,\hat{i} - \cos\theta\,\hat{j}\right)\cdot d\vec{s}$$

Express the radial vector $\vec{r}$ in terms of its magnitude r and the angle θ it makes with the positive x axis:

$$\vec{r} = r\cos\theta\,\hat{i} + r\sin\theta\,\hat{j}$$

The differential of $\vec{r}$ is tangent to the circle (you can easily convince yourself of this by forming the dot product of $\vec{r}$ and $d\vec{r}$) and so we can use it as $d\vec{s}$ in our expression for the work done by $\vec{F}$ in one revolution:

$$d\vec{r} = d\vec{s} = -r\sin\theta\,d\theta\,\hat{i} + r\cos\theta\,d\theta\,\hat{j} = \left(-r\sin\theta\,\hat{i} + r\cos\theta\,\hat{j}\right)d\theta$$

Substitute for $d\vec{s}$, simplifying, and integrate to obtain:

$$W_{1\,\text{rev,ccw}} = F_0\int_0^{2\pi}\left(\sin\theta\,\hat{i} - \cos\theta\,\hat{j}\right)\cdot\left(-r\sin\theta\,\hat{i} + r\cos\theta\,\hat{j}\right)d\theta$$
$$= -rF_0\int_0^{2\pi}\left(\sin^2\theta + \cos^2\theta\right)d\theta = -rF_0\int_0^{2\pi}d\theta = -rF_0\,\theta\Big]_0^{2\pi}$$
$$= -2\pi rF_0$$

Substituting the numerical value of r yields:

$$W_{1\text{rev, ccw}} = -2\pi(5.0\text{ m})F_0 = \boxed{(-10\pi\text{ m})F_0}$$

If the rotation is clockwise, the integral becomes:

$$W_{1\,\text{rev,cw}} = -rF_0\,\theta\Big]_{2\pi}^{0} = 2\pi rF_0$$

Substituting the numerical value of r yields:

$$W_{1\text{rev, cw}} = 2\pi(5.0\text{ m})F_0 = \boxed{(10\pi\text{ m})F_0}$$

72 ••• A force acting on a 2.0-kg particle in the *xy* plane at coordinates (*x*, *y*) is given by $\vec{F} = -\left(b/r^3\right)\left(x\,\hat{i} + y\,\hat{j}\right)$, where *b* is a positive constant and *r* is the

distance from the origin. (a) Show that the magnitude of the force is inversely proportional to r^2, and that its direction is antiparallel (opposite) to the radius vector $\vec{r} = x\hat{\boldsymbol{i}} + y\hat{\boldsymbol{j}}$. ($b$) If $b = 3.0\ \text{N}\cdot\text{m}^2$, find the work done by this force as the particle moves from (2.0 m, 0.0 m), to (5.0 m, 0.0 m) along a straight-line path. (c) Find the work done by this force on a particle moving once around a circle of radius r = 7.0 m that is centered at the origin.

Comment: DAVID: Part (d) has be deleted.

Picture the Problem We can substitute for r and $x\hat{\boldsymbol{i}} + y\hat{\boldsymbol{j}}$ in $\vec{F}$ to show that the magnitude of the force varies as the reciprocal of the square of the distance to the origin, and that its direction is opposite to the radius vector. We can find the work done by this force by evaluating the integral of F with respect to x from an initial position x = 2.0 m, y = 0 m to a final position x = 5.0 m, y = 0 m. Finally, we can apply Newton's second law to the particle to relate its speed to its radius, mass, and the constant b.

(a) Express the magnitude of $\vec{F}$:

$$\left|\vec{F}\right| = \sqrt{F_x^2 + F_y^2} = \sqrt{\left(-\frac{b}{r^3}x\right)^2 + \left(-\frac{b}{r^3}y\right)^2} = \frac{b}{r^3}\sqrt{x^2+y^2}$$

The magnitude of r is given by:

$$r = \sqrt{x^2+y^2}$$

Substitute for $\sqrt{x^2+y^2}$ and simplify to obtain:

$$\left|\vec{F}\right| = \frac{b}{r^3}r = \boxed{\frac{b}{r^2}}$$

That is, the magnitude of the force varies inversely with the square of the distance to the origin. Because $\vec{F} = -\left(b/r^3\right)\vec{r}$, the direction of $\vec{F}$ is opposite the direction of $\vec{r}$.

(b) Find the work done by this force by evaluating the integral of F with respect to x from an initial position x = 2.0 m, y = 0 m to a final position x = 5.0 m, y = 0 m:

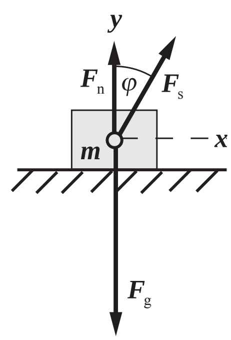
$$W = -\int_{2.0\,\text{m}}^{5.0\,\text{m}} \frac{b}{x^2}dx = b\left[\frac{1}{x}\right]_{2.0\,\text{m}}^{5.0\,\text{m}} = 3.0\ \text{N}\cdot\text{m}^2\left(\frac{1}{5.0\ \text{m}} - \frac{1}{2.0\ \text{m}}\right) = \boxed{-0.90\ \text{J}}$$

(c) No work is done as the force is perpendicular to the velocity.

73 ••• A block of mass m on a horizontal frictionless tabletop is attached by a swivel to a spring that is attached to the ceiling (Figure 6-39). The vertical distance between the top of the block and the ceiling is y_o, and the horizontal position is x. When the block is at $x = 0$, the spring, which has force constant k, is completely unstressed. (a) What is F_x, the x component of the force on the block due to the spring, as a function of x? (b) Show that F_x is proportional to x^3 for sufficiently small values of $|x|$. (c) If the block is released from rest at $x = x_0$, where $|\mathbf{x}_0| << \mathbf{y}_0$, what is its speed when it reaches $x = 0$?

Comment: DAVID: The initial position has be labeled x_0.

Picture the Problem We can use trigonometry to express the x-component of $\vec{F}_s$ and the Pythagorean theorem to write it as a function of x. Expanding on of the terms in F_x binomially reveals its cubic dependence on x. In (c), we can apply the work-kinetic energy theorem and use the definition of work to find the speed of the block when it reaches $x = 0$.



(a) F_x, the x-component of $\vec{F}_s$, is given by:

$$F_x = -F_s \sin\varphi \quad (1)$$

Express F_s when the length of the spring is ℓ:

$$F_s = k(\ell - y_0)$$

Substituting for F_s in equation (1) yields:

$$F_x = -k(\ell - y_0)\sin\varphi \quad (2)$$

Referring to the figure, note that:

$$\sin\varphi = \frac{x}{\ell}$$

Substitute for $\sin\varphi$ to obtain:

$$F_x = -k(\ell - y_0)\frac{x}{\ell} = -kx\left(1 - \frac{y_0}{\ell}\right) \quad (3)$$

Refer to the figure again to see that:

$$\ell^2 = \mathbf{x}^2 + \mathbf{y}_0^2 \Rightarrow \ell = \sqrt{\mathbf{x}^2 + \mathbf{y}_0^2}$$

Substituting for ℓ in equation (3) yields:

$$F_x = \boxed{-kx\left(1 - \frac{y_0}{\sqrt{x^2 + y_0^2}}\right)} \quad (4)$$

(b) Rewrite the second term in parentheses in equation (4) by dividing numerator and denominator by y_0 to obtain:

$$F_x = -kx\left(1 - \frac{1}{\frac{1}{y_0}\sqrt{x^2 + y_0^2}}\right) = -kx\left(1 - \frac{1}{\sqrt{1 + \frac{x^2}{y_0^2}}}\right) = -kx\left(1 - \left(1 + \frac{x^2}{y_0^2}\right)^{-\frac{1}{2}}\right)$$

Expanding $\left(1 + \frac{x^2}{y_0^2}\right)^{-\frac{1}{2}}$ binomially yields:

$$\left(1 + \frac{x^2}{y_0^2}\right)^{-\frac{1}{2}} = 1 + \frac{1}{2}\frac{x^2}{y_0^2} + \text{higher order terms}$$

For $x << y_0$, we can ignore the higher –order terms and :

$$\left(1 + \frac{x^2}{y_0^2}\right)^{-\frac{1}{2}} \approx 1 + \frac{1}{2}\frac{x^2}{y_0^2}$$

Substitute for $\left(1 + \frac{x^2}{y_0^2}\right)^{-\frac{1}{2}}$ in the expression for F_x and simplify to obtain:

$$F_x = -kx\left[1 - \left(1 + \frac{1}{2}\frac{x^2}{y_0^2}\right)\right] = \boxed{-\frac{k}{2y_0^2}x^3}$$

(c) Apply the work-kinetic energy theorem to the block to obtain:

$$W_{\text{total}} = \Delta K = K_{\text{f}} - K_{\text{i}}$$

or, because the block is released from rest,

$$W_{\text{total}} = K_{\text{f}} = \tfrac{1}{2}mv_{\text{f}}^2 \qquad (5)$$

Integrate F_x to obtain:

$$W_{\text{total}} = -\frac{k}{2y_0^2}\int_L^0 x^3 dx = \frac{kL^4}{8y_0^2}$$

Substitute for W_{total} in equation (5):

$$\frac{kL^4}{8y_0^2} = \tfrac{1}{2}mv_{\text{f}}^2 \Rightarrow v_{\text{f}} = \boxed{\frac{L^2}{2y_0}\sqrt{\frac{k}{m}}}$$

74 •• Two horses pull a large crate at constant speed across a barn floor by means of two light steel cables. A large box of mass 250 kg sits on the crate (Figure 6-40). As the horses pull, the cables are parallel to the horizontal floor. The coefficient of friction between the crate and the barn floor is 0.25. (a) What is the work done by each horse if the box is moved a distance of 25 m? (b) What

is the tension in each cable if the angle between each cable and the direction the crate moves is 15°?

Picture the Problem We can apply the work-kinetic energy theorem to the crate to relate the work done by the horses and the work done by the friction force. In part (*b*), we can use the definition of work and our result from Part (*a*) to find the tension in the cables.

(*a*) Apply the work-kinetic energy theorem to the crate to obtain:

$$W_{\text{total}} = W_{\text{horses}} + W_{\text{friction}} = \Delta K$$

or, because the horses pull the crate at constant speed, $\Delta K = 0$, and

$$W_{\text{horses}} + W_{\text{friction}} = 0 \qquad (1)$$

The work done by friction is given by:

$$W_{\text{friction}} = \vec{\boldsymbol{f}}_{\text{k}} \cdot \vec{\boldsymbol{d}} = f_{\text{k}} d \cos\phi$$

where ϕ is the angle between $\vec{\boldsymbol{f}}_{\text{k}}$ and $\vec{\boldsymbol{d}}$.

Because $\vec{\boldsymbol{f}}_{\text{k}}$ and $\vec{\boldsymbol{d}}$ are in opposite directions:

$$W_{\text{friction}} = -f_{\text{k}} d$$

Because the normal force acting on the crate equals the weight of the crate:

$$W_{\text{friction}} = -\mu_{\text{k}} F_{\text{n}} d = -\mu_{\text{k}} mgd$$

Substitute for W_{friction} in equation (1) to obtain:

$$W_{\text{horses}} - \mu_{\text{k}} mgd = 0$$

and

$$W_{\text{horses}} = \mu_{\text{k}} mgd$$

Because each horse does half the work:

$$W_{\text{each horse}} = \tfrac{1}{2} W_{\text{horses}} = \tfrac{1}{2} \mu_{\text{k}} mgd$$

Substitute numerical values and evaluate $W_{\text{each horse}}$:

$$W_{\text{each horse}} = \tfrac{1}{2}(0.25)(250\ \text{kg})(9.81\ \text{m/s}^2)(25\ \text{m}) = 7.664\ \text{kJ} = \boxed{7.7\ \text{kJ}}$$

(*b*) The work done by each horse as a function of the tension in each cable:

$$W_{\text{each horse}} = \vec{\boldsymbol{T}} \cdot \vec{\boldsymbol{d}} = Td\cos\theta$$

Solving for *T* yields:

$$T = \frac{W_{\text{each horse}}}{d\cos\theta}$$

Substitute numerical values and evaluate *T*:

$$T = \frac{7.664\ \text{kJ}}{(25\ \text{m})\cos 15°} = \boxed{0.32\ \text{kN}}$$

Chapter 7
The Conservation of Energy

Conceptual Problems

1 • [SSM] Two cylinders of unequal mass are connected by a massless cord that passes over a frictionless pulley (Figure 7-34). After the system is released from rest, which of the following statements are true? (U is the gravitational potential energy and K is the kinetic energy of the system.)
(a) $\Delta U < 0$ and $\Delta K > 0$, (b) $\Delta U = 0$ and $\Delta K > 0$, (c) $\Delta U < 0$ and $\Delta K = 0$,
(d) $\Delta U = 0$ and $\Delta K = 0$, (e) $\Delta U > 0$ and $\Delta K < 0$.

Determine the Concept Because the pulley is frictionless, mechanical energy is conserved as this system evolves from one state to another. The system moves and so we know that $\Delta K > 0$. Because $\Delta K + \Delta U = constant$, $\Delta U < 0$. $\boxed{(a)}$ is correct.

2 • Two stones are simultaneously thrown with the same initial speed from the roof of a building. One stone is thrown at an angle of 30° above the horizontal, the other is thrown horizontally. (Neglect effects due to air resistance.) Which statement below is true?

(a) The stones strike the ground at the same time and with equal speeds.
(b) The stones strike the ground at the same time with different speeds.
(c) The stones strike the ground at different times with equal speeds.
(d) The stones strike the ground at different times with different speeds.

Determine the Concept Choose the zero of gravitational potential energy to be at ground level. The two stones have the same initial energy because they are thrown from the same height with the same initial speeds. Therefore, they will have the same total energy at all times during their fall. When they strike the ground, their gravitational potential energies will be zero and their kinetic energies will be equal. Thus, their speeds at impact will be equal. The stone that is thrown at an angle of 30° above the horizontal has a longer flight time due to its initial upward velocity and so they do not strike the ground at the same time. $\boxed{(c)}$ is correct.

3 • True or false:

(a) The total energy of a system cannot change.
(b) When you jump into the air, the floor does work on you increasing your mechanical energy.
(c) Work done by frictional forces must always decrease the total mechanical energy of a system.
(d) Compressing a given spring 2.0 cm from its unstressed length takes more work than stretching it 2.0 cm from its unstressed length.

(*a*) False. Forces that are external to a system can do work on the system to change its energy.

(*b*) False. In order for some object to do work, it must exert a force *over some distance*. The mechanical energy gained by the jumper comes from the internal energy of the jumper, not from the floor.

(*c*) False. The frictional force that accelerates a sprinter increases the total mechanical energy of the sprinter.

(*d*) False. Because the work required to stretch a spring a given distance varies as the square of that distance, the work is the same regardless of whether the spring is stretched or compressed.

4 • As a novice ice hockey player (assume frictionless situation), you have not mastered the art of stopping except by coasting straight for the boards of the rink (assumed to be a rigid wall). Discuss the energy changes that occur as you use the boards to slow your motion to a stop.

Determine the Concept The boards do not do any work on you. Your loss of kinetic energy is converted into thermal energy of your body.

5 • True or false (The particle in this question can move only along the *x* axis and is acted on by only one force, and $U(x)$ is the potential-energy function associated with this force.):

(*a*) The particle will be in equilibrium if it is at a location where $dU/dx = 0$.
(*b*) The particle will accelerate in the –*x* direction if it is at a location where $dU/dx > 0$.
(*c*) The particle will both be in equilibrium and have constant speed if it is at a section of the *x* axis where $dU/dx = 0$ throughout the section.
(*d*) The particle will be in stable equilibrium if it is at a location where both $dU/dx = 0$ and $d^2U/dx^2 > 0$.
(*e*) The particle will be in neutral equilibrium if it is at a location where both $dU/dx = 0$ and $d^2U/dx^2 > 0$.

Determine the Concept dU/dx is the slope of the graph of $U(x)$ and d^2U/dx^2 is the rate at which the slope is changing. The force acting on the object is given by $F = -dU/dx$.

(*a*) True. If $dU/dx = 0$, then the net force acting on the object is zero (the condition for equilibrium).

(*b*) True. If $dU/dx > 0$ at a given location, then the net force acting on the object is negative and its acceleration is to the left.

(*c*) True. If $dU/dx = 0$ over a section of the *x* axis, then the net force acting on the object is zero and its acceleration is zero.

(*d*) True. If $dU/dx = 0$ and $d^2U/dx^2 > 0$ at a given location, then $U(x)$ is concave upward at that location (the condition for stable equilibrium).

(*e*) False. If $dU/dx = 0$ and $d^2U/dx^2 > 0$ at a given location, then $U(x)$ is concave upward at that location (the condition for stable equilibrium).

6 • Two knowledge seekers decide to ascend a mountain. Sal chooses a short, steep trail, while Joe, who weighs the same as Sal, chooses a long, gently sloped trail. At the top, they get into an argument about who gained more potential energy. Which of the following is true:

(*a*) Sal gains more gravitational potential energy than Joe.
(*b*) Sal gains less gravitational potential energy than Joe.
(*c*) Sal gains the same gravitational potential energy as Joe.
(*d*) To compare the gravitational potential energies, we must know the height of the mountain.
(*e*) To compare the gravitational potential energies, we must know the length of the two trails.

Determine the Concept The change in gravitational potential energy, over elevation changes that are small enough so that the gravitational field can be considered constant, is $mg\Delta h$, where Δh is the elevation change. Because Δh is the same for both Sal and Joe, their gains in gravitational potential energy are the same. $\boxed{(c)}$ is correct.

7 • True or false:

(*a*) Only conservative forces can do work.
(*b*) If only conservative forces act on a particle, the kinetic energy of the particle can not change.
(*c*) The work done by a conservative force equals the change in the potential energy associated with that force.

(d) If, for a particle constrained to the x axis, the potential energy associated with a conservative force decreases as the particle moves to the right, then the force points to the left.
(e) If, for a particle constrained to the x axis, a conservative force points to the right, then the potential energy associated with the force increases as the particle moves to the left.

(a) False. The definition of work is not limited to displacements caused by conservative forces.

(b) False. Consider the work done by the gravitational force on an object in freefall.

(c) False. The work done may change the kinetic energy of the system.

(d) False. The direction of the force is given by $F = -dU/dx$, so if the potential energy is decreasing to the right (the slope of $U(x)$ is negative), F must be positive (that is, points to the right).

(e) True. The direction of the force is given by $F = -dU/dx$, so if F points to the right, the potential energy function must increase to the left.

8 • Figure 7-35 shows the plot of a potential-energy function U versus x. (a) At each point indicated, state whether the x component of the force associated with this function is positive, negative, or zero. (b) At which point does the force have the greatest magnitude? (c) Identify any equilibrium points, and state whether the equilibrium is stable, unstable, or neutral

Picture the Problem F_x is defined to be the negative of the derivative of the potential-energy function with respect to x; that is, $F_x = -dU/dx$.

(a) Examine the slopes of the curve at each of the lettered points, remembering that F_x is the negative of the slope of the potential energy graph, to complete the table:

Point	dU/dx	F_x
A	+	–
B	0	0
C	–	+
D	0	0
E	+	–
F	0	0

(b) Find the point where the slope is steepest:

$|F_x|$ is greatest at point C.

(c) If $d^2U/dx^2 < 0$, then the curve is concave downward and the equilibrium is *unstable*.

The equilibrium is unstable at point B.

If $d^2U/dx^2 > 0$, then the curve is concave upward and the equilibrium is *stable*.

The equilibrium is stable at point D.

Remarks: At point F, if $d^2U/dx^2 = 0$ while the fourth derivative is positive, then the equilibrium is *stable*.

9 • Assume that, when the brakes are applied, a constant frictional force is exerted on the wheels of a car by the road. If that is so, then which of the following are necessarily true? (a) The distance the car travels before coming to rest is proportional to the speed of the car just as the brakes are first applied, (b) the car's kinetic energy diminishes at a constant rate, (c) the kinetic energy of the car is inversely proportional to the time that has elapsed since the application of the brakes, (d) none of the above.

Picture the Problem Because the constant friction force is responsible for a constant acceleration, we can apply the constant-acceleration equations to the analysis of these statements. We can also apply the work-energy theorem with friction to obtain expressions for the kinetic energy of the car and the rate at which it is changing. Choose the system to include Earth and car and assume that the car is moving on a horizontal surface so that $\Delta U = 0$.

(a) A constant frictional force causes a constant acceleration. The stopping distance of the car is related to its speed before the brakes were applied through a constant-acceleration equation.

$$v^2 = v_0^2 + 2a\Delta s$$

or, because $v = 0$,

$$0 = v_0^2 + 2a\Delta s \Rightarrow \Delta s = \frac{-v_0^2}{2a}$$

where $a < 0$.

Thus, $\Delta s \propto v_0^2$:

Statement (a) is *false*.

(b) Apply the work-energy theorem with friction to obtain:

$$\Delta K = -W_{\text{f}} = -\mu_{\text{k}} mg\Delta s$$

Express the rate at which K is dissipated:

$$\frac{\Delta K}{\Delta t} = -\mu_{\text{k}} mg \frac{\Delta s}{\Delta t}$$

Thus, $\dfrac{\Delta K}{\Delta t} \propto v$ and therefore not constant.

Statement (*b*) is *false*.

(*c*) In Part (*b*) we saw that:

$K \propto \Delta s$

Because $\Delta s \propto \Delta t$ and $K \propto \Delta t$:

Statement (*c*) is *false*.

Because none of the above are correct:

$\boxed{(d)}$ is correct.

10 •• If a rock is attached to a massless, rigid rod and swung in a vertical circle (Figure 7-36) at a constant speed, the total mechanical energy of the rock-Earth system does not remain constant. The kinetic energy of the rock remains constant, but the gravitational potential energy is continually changing. Is the total work done on the rock equal to zero during all time intervals? Does the force by the rod on the rock ever have a nonzero tangential component?

Determine the Concept No. From the work-kinetic energy theorem, no total work is being done on the rock, as its kinetic energy is constant. However, the rod must exert a tangential force on the rock to keep the speed constant. The effect of this force is to cancel the component of the force of gravity that is tangential to the trajectory of the rock.

11 •• Use the rest energies given in Table 7-1 to answer the following questions. (*a*) Can the triton naturally decay into a helion? (*b*) Can the alpha particle naturally decay into helion plus a neutron? (*c*) Can the proton naturally decay into a neutron and a positron?

Determine the Concept
(*a*) Yes, because the triton mass is slightly more than that of the helion (^{3}He) mass.

(*b*) No, because the total of the neutron and helion masses is 3747.96 MeV which is larger than the alpha particle mass.

(*c*) No, because the neutron mass is already larger than that of the proton.

Estimation and Approximation

12 • Estimate (*a*) the change in your potential energy on taking an elevator from the ground floor to the top of the Empire State building, (*b*) the average force acting on you by the elevator to bring you to the top, and (*c*) the average power due to that force. The building is 102 stories high.

Picture the Problem You can estimate your change in potential energy due to this change in elevation from the definition of ΔU. You'll also need to estimate the height of one story of the Empire State building. We'll assume your mass is 70.0 kg and the height of one story to be 3.50 m. This approximation gives us a height of 1170 ft (357 m), a height that agrees to within 7% with the actual height of 1250 ft from the ground floor to the observation deck. We'll also assume that it takes 3 min to ride non-stop to the top floor in one of the high-speed elevators.

(*a*) Express the change in your gravitational potential energy as you ride the elevator to the 102nd floor:

$$\Delta U = mg\Delta h$$

Substitute numerical values and evaluate ΔU:

$$\Delta U = (70.0\,\text{kg})(9.81\,\text{m/s}^2)(357\,\text{m}) = 245.2\,\text{kJ} = \boxed{245\,\text{kJ}}$$

(*b*) Ignoring the acceleration intervals at the beginning and the end of your ride, express the work done on you by the elevator in terms of the change in your gravitational potential energy:

$$W = Fh = \Delta U \Rightarrow F = \frac{\Delta U}{h}$$

Substitute numerical values and evaluate F:

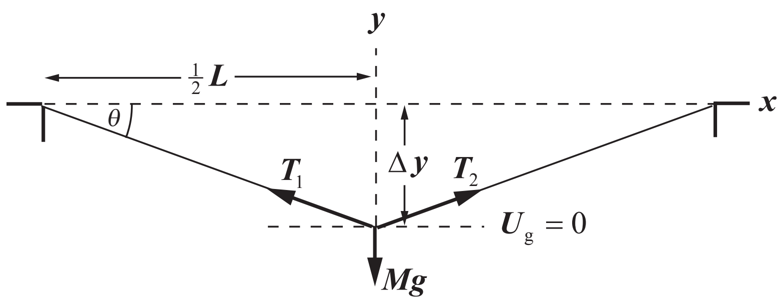
$$F = \frac{245.2\,\text{kJ}}{357\,\text{m}} = \boxed{687\,\text{N}}$$

(*c*) Assuming a 3 min ride to the top, the average power delivered to the elevator is:

$$P = \frac{\Delta U}{\Delta t} = \frac{245.2\,\text{kJ}}{(3\,\text{min})(60\,\text{s/min})} = \boxed{1.36\,\text{kW}}$$

13 • A tightrope walker whose mass is 50 kg walks across a tightrope held between two supports 10 m apart; the tension in the rope is 5000 N when she stands at the exact center of the rope. Estimate: (*a*) the sag in the tightrope when the acrobat stands in the exact center, and (*b*) the change in her gravitational potential energy from when she steps onto the tightrope to when she stands at its exact center.

Picture the Problem The diagram depicts the situation when the tightrope walker is at the center of rope and shows a coordinate system in which the +*x* direction is to the right and +*y* direction is upward. *M* represents her mass and the vertical components of tensions $\vec{T}_1$ and $\vec{T}_2$, which are equal in magnitude, support her weight. We can apply a condition for static equilibrium in the vertical direction to relate the tension in the rope to the angle θ and use trigonometry to find Δy as a function of θ.



(*a*) Use trigonometry to relate the sag Δy in the rope to its length L and θ:

$$\tan\theta = \frac{\Delta y}{\frac{1}{2}L} \Rightarrow \Delta y = \tfrac{1}{2}L\tan\theta \quad (1)$$

Apply $\sum F_y = 0$ to the tightrope walker when she is at the center of the rope to obtain:

$$2T\sin\theta - Mg = 0$$

where T is the magnitude of $\vec{T}_1$ and $\vec{T}_2$.

Solve for θ to obtain:

$$\theta = \sin^{-1}\left(\frac{Mg}{2T}\right)$$

Substituting for θ in equation (1) yields:

$$\Delta y = \tfrac{1}{2}L\tan\left[\sin^{-1}\left(\frac{Mg}{2T}\right)\right]$$

Substitute numerical values and evaluate Δy:

$$\Delta y = \tfrac{1}{2}(10\text{ m})\tan\left[\sin^{-1}\left[\frac{(50\text{ kg})(9.81\text{ m/s}^2)}{2(5000\text{ N})}\right]\right] = 0.2455\text{ m} = \boxed{25\text{ cm}}$$

(*b*) Express the change in the tightrope walker's gravitational potential energy as the rope sags:

$$\Delta U = U_{\text{at center}} - U_{\text{end}} = 0 + Mg\Delta y$$
$$= Mg\Delta y$$

Substitute numerical values and evaluate ΔU:

$$\Delta U = (50\text{ kg})(9.81\text{ m/s}^2)(-0.2455\text{ m})$$
$$= \boxed{-0.12\text{ kJ}}$$

14 •• *The metabolic rate* is defined as the rate at which the body uses chemical energy to sustain its life functions. The average metabolic rate has been found to be proportional to the total skin surface area of the body. The surface area for a 5-ft, 10-in. male weighing 175 lb is about 2.0 m^2, and for a 5-ft, 4-in. female weighing 110 lb it is approximately 1.5 m^2. There is about a 1 percent change in surface area for every three pounds above or below the weights quoted here and a 1 percent change for every inch above or below the heights quoted. (*a*) Estimate your average metabolic rate over the course of a day using the following guide for metabolic rates (per square meter of skin area) for various

physical activities: sleeping, 40 W/m^2; sitting, 60 W/m^2; walking, 160 W/m^2; moderate physical activity, 175 W/m^2; and moderate aerobic exercise, 300 W/m^2. How do your results compare to the power of a 100-W light bulb? (*b*) Express your average metabolic rate in terms of kcal/day (1 kcal = 4.19 kJ). (A kcal is the ″food calorie″ used by nutritionists.) (*c*) An estimate used by nutritionists is that each day the ″average person″ must eat roughly 12–15 kcal of food for each pound of body weight to maintain his or her weight. From the calculations in Part (*b*), are these estimates plausible?

Picture the Problem We'll use the data for the "typical male" described above and assume that he spends 8 hours per day sleeping, 2 hours walking, 8 hours sitting, 1 hour in aerobic exercise, and 5 hours doing moderate physical activity. We can approximate his energy utilization using $E_{\text{activity}} = AP_{\text{activity}}\Delta t_{\text{activity}}$, where A is the surface area of his body, P_{activity} is the rate of energy consumption in a given activity, and $\Delta t_{\text{activity}}$ is the time spent in the given activity. His total energy consumption will be the sum of the five terms corresponding to his daily activities.

(*a*) Express the energy consumption of the hypothetical male:

$$E = E_{\text{sleeping}} + E_{\text{walking}} + E_{\text{sitting}} + E_{\text{mod. act.}} + E_{\text{aerobic act.}} \qquad (1)$$

Evaluate E_{sleeping}:

$$\begin{aligned} E_{\text{sleeping}} &= AP_{\text{sleeping}}\Delta t_{\text{sleeping}} = \left(2.0\,\text{m}^2\right)\left(40\,\text{W/m}^2\right)\left(8.0\,\text{h}\right)\left(3600\,\text{s/h}\right) \\ &= 2.30\times10^{6}\ \text{J} \end{aligned}$$

Evaluate E_{walking}:

$$\begin{aligned} E_{\text{walking}} &= AP_{\text{walking}}\Delta t_{\text{walking}} = \left(2.0\,\text{m}^2\right)\left(160\,\text{W/m}^2\right)\left(2.0\,\text{h}\right)\left(3600\,\text{s/h}\right) \\ &= 2.30\times10^{6}\ \text{J} \end{aligned}$$

Evaluate E_{sitting}

$$\begin{aligned} E_{\text{sitting}} &= AP_{\text{sitting}}\Delta t_{\text{sitting}} = \left(2.0\,\text{m}^2\right)\left(60\,\text{W/m}^2\right)\left(8.0\,\text{h}\right)\left(3600\,\text{s/h}\right) \\ &= 3.46\times10^{6}\ \text{J} \end{aligned}$$

Evaluate $E_{\text{mod. act.}}$:

$$E_{\text{mod. act.}} = AP_{\text{mod. act.}}\Delta t_{\text{mod. act.}} = \left(2.0\,\text{m}^2\right)\left(175\,\text{W/m}^2\right)\left(5.0\,\text{h}\right)\left(3600\,\text{s/h}\right)$$
$$= 6.30\times10^6\ \text{J}$$

Evaluate $E_{\text{aerobic act.}}$:

$$E_{\text{aerobic act.}} = AP_{\text{aerobic act.}}\Delta t_{\text{aerobic act.}} = \left(2.0\,\text{m}^2\right)\left(300\,\text{W/m}^2\right)\left(1.0\,\text{h}\right)\left(3600\,\text{s/h}\right)$$
$$= 2.16\times10^6\ \text{J}$$

Substitute numerical values in equation (1) and evaluate E:

$$E = 2.30\times10^6\ \text{J} + 2.30\times10^6\ \text{J} + 3.46\times10^6\ \text{J} + 6.30\times10^6\ \text{J} + 2.16\times10^6\ \text{J}$$
$$= 16.5\times10^6\ \text{J} = \boxed{17\ \text{MJ}}$$

Express the average metabolic rate represented by this energy consumption:

$$P_{\text{av}} = \frac{E}{\Delta t}$$

Substitute numerical values and evaluate P_{av}:

$$P_{\text{av}} = \frac{16.5\times10^6\ \text{J}}{\left(24\,\text{h}\right)\left(3600\,\text{s/h}\right)} = \boxed{0.19\,\text{kW}}$$

or about twice that of a 100 W light bulb.

(*b*) Express his average energy consumption in terms of kcal/day:

$$E = \frac{16.5\times10^6\ \text{J/d}}{4190\,\text{J/kcal}} = 3938\,\text{kcal/d}$$
$$\approx \boxed{3.9\,\text{Mcal/d}}$$

(*c*) $\dfrac{3940\,\text{kcal}}{175\,\text{lb}} \approx 23\dfrac{\text{kcal}}{\text{lb}}$ is higher than the estimate given in the statement of the problem. However, by adjusting the day's activities, the metabolic rate can vary by more than a factor of 2.

15 •• [SSM] Assume that your maximum metabolic rate (the maximum rate at which your body uses its chemical energy) is 1500 W (about 2.7 hp). Assuming a 40 percent efficiency for the conversion of chemical energy into mechanical energy, estimate the following: (*a*) the shortest time you could run up four flights of stairs if each flight is 3.5 m high, (*b*) the shortest time you could climb the Empire State Building (102 stories high) using your Part (*a*) result. Comment on the feasibility of you actually achieving Part (*b*) result.

Picture the Problem The rate at which you expend energy, that is do work, is defined as *power* and is the ratio of the work done to the time required to do the work.

(*a*) Relate the rate at which you can expend energy to the work done in running up the four flights of stairs:

$$\varepsilon P = \frac{\Delta W}{\Delta t} \Rightarrow \Delta t = \frac{\Delta W}{\varepsilon P}$$

where *e* is the efficiency for the conversion of chemical energy into mechanical energy.

The work you do in climbing the stairs increases your gravitational potential energy:

$$\Delta W = mgh$$

Substitute for ΔW to obtain:

$$\Delta t = \frac{mgh}{\varepsilon P} \qquad (1)$$

Assuming that your mass is 70 kg, substitute numerical values in equation (1) and evaluate Δt:

$$\Delta t = \frac{(70\,\text{kg})(9.81\,\text{m/s}^2)(4\times 3.5\,\text{m})}{(0.40)(1500\,\text{W})} \approx \boxed{16\,\text{s}}$$

(*b*) Substituting numerical values in equation (1) yields:

$$\Delta t = \frac{(70\,\text{kg})(9.81\,\text{m/s}^2)(102\times 3.5\,\text{m})}{(0.40)(1500\,\text{W})} = 409\,\text{s} \approx \boxed{6.8\,\text{min}}$$

The time of about 6.8 min is clearly not reasonable. The fallacy is that you cannot do work at the given rate of 1500 W for more than very short intervals of time.

16 •• You are in charge of determining when the uranium fuel rods in a local nuclear power plant are to be replaced with fresh ones. To make this determination you decide to estimate how much the mass of a core of a nuclear-fueled electric-generating plant is reduced per unit of electric energy produced. (*Note:* In such a generating plant the reactor core generates thermal energy, which is then transformed to electric energy by a steam turbine. It requires 3.0 J of thermal energy for each 1.0 J of electric energy produced.) What are your results for the production of (*a*) 1.0 J of thermal energy? (*b*) enough electric energy to keep a 100-W light bulb burning for 10.0 y? (*c*) electric energy at a constant rate of 1.0 GW for a year? (This is typical of modern plants.)

Picture the Problem The intrinsic rest energy in matter is related to the mass of matter through Einstein's equation $E_0 = mc^2$.

(*a*) Relate the rest mass consumed to the energy produced and solve for *m*:

$$E_0 = mc^2 \Rightarrow m = \frac{E_0}{c^2} \qquad (1)$$

Substitute numerical values and evaluate *m*:

$$m = \frac{1.0\,\text{J}}{(2.998\times10^8\ \text{m/s})^2} = \boxed{1.1\times10^{-17}\ \text{kg}}$$

(*b*) Because the reactor core must produce 3 J of thermal energy for each joule of electrical energy produced:

$$E = 3P\Delta t$$

Substitute for E_0 in equation (1) to obtain:

$$m = \frac{3P\Delta t}{c^2} \qquad (2)$$

Substitute numerical values in equation (2) and evaluate *m*:

$$m = \frac{3(100\ \text{W})(10\ \text{y})\left(\frac{365.24\,\text{d}}{\text{y}}\right)\left(\frac{24\,\text{h}}{\text{d}}\right)\left(\frac{3600\,\text{s}}{\text{h}}\right)}{(2.998\times10^8\ \text{m/s})^2} = \boxed{1.1\times10^{-6}\ \text{kg}}$$

(*c*) Substitute numerical values in equation (2) and evaluate *m*:

$$m = \frac{3(1.0\,\text{GW})(1.0\,\text{y})\left(\frac{365.24\,\text{d}}{\text{y}}\right)\left(\frac{24\,\text{h}}{\text{d}}\right)\left(\frac{3600\,\text{s}}{\text{h}}\right)}{(2.998\times10^8\ \text{m/s})^2} = \boxed{1.1\,\text{kg}}$$

17 •• [SSM] The chemical energy released by burning a gallon of gasoline is approximately 1.3×10^5 kJ. Estimate the total energy used by all of the cars in the United States during the course of one year. What fraction does this represent of the total energy use by the United States in one year (currently about 5×10^{20} J)?

Picture the Problem There are about 3×10^8 people in the United States. On the assumption that the average family has 4 people in it and that they own two cars, we have a total of 1.5×10^8 automobiles on the road (excluding those used for industry). We'll assume that each car uses about 15 gal of fuel per week.

Calculate, based on the assumptions identified above, the total annual consumption of energy derived from gasoline:

$$\left(1.5\times10^{8}\,\text{auto}\right)\left(15\frac{\text{gal}}{\text{auto}\cdot\text{week}}\right)\left(52\frac{\text{weeks}}{\boldsymbol{y}}\right)\left(1.3\times10^{5}\,\frac{\text{kJ}}{\text{gal}}\right)=\boxed{1.5\times10^{19}\ \text{J/y}}$$

Express this rate of energy use as a fraction of the total annual energy use by the United States:

$$\frac{1.5\times10^{19}\ \text{J/y}}{5\times10^{20}\ \text{J/y}}\approx\boxed{3\%}$$

18 •• The maximum efficiency of a solar-energy panel in converting solar energy into useful electrical energy is currently about 12 percent. In a region such as the southwestern United States the solar intensity reaching Earth's surface is about 1.0 kW/m^2 on average during the day. Estimate the area that would have to be covered by solar panels in order to supply the energy requirements of the United States (approximately 5×10^{20} J/y) and compare it to the area of Arizona. Assume cloudless skies.

Picture the Problem The energy consumption of the U.S. works out to an average power consumption of about 1.6×10^{13} watt. The solar constant is roughly 10^3 W/m^2 (reaching the ground), or about 120 W/m^2 of useful power with a 12% conversion efficiency. Letting P represent the daily rate of energy consumption, we can relate the power available at the surface of Earth to the required area of the solar panels using $P = IA$. Using the internet, one finds that the area of Arizona is about 114,000 mi^2 or 3.0×10^{11} m^2.

Relate the required area to the electrical energy to be generated by the solar panels:

$$A=\frac{P}{I}=\frac{\Delta E}{I\Delta t}$$

where I is the solar intensity that reaches the surface of Earth.

Substitute numerical values and evaluate A:

$$A=\frac{2\left(5\times10^{20}\ \text{J}/y\right)}{\left(120\,\text{W/m}^2\right)\left(1\ \text{y}\right)\left(3.156\times10^{7}\ \text{s/y}\right)}$$

$$=2.640\times10^{11}\ \text{m}^2=\boxed{2.6\times10^{11}\ \text{m}^2}$$

where the factor of 2 comes from the fact that the sun is only "up" for roughly half the day.

Express the ratio of A to the area of Arizona to obtain:

$$\frac{A}{A_{\text{Arizona}}}=\frac{2.640\times10^{11}\ \text{m}^2}{3.0\times10^{11}\ \text{m}^2}\approx0.88$$

That is, the required area is about 88% of the area of Arizona.

Remarks: A more realistic estimate that would include the variation of sunlight over the day and account for latitude and weather variations might very well increase the area required by an order of magnitude.

19 •• Hydroelectric power plants convert gravitational potential energy into more useful forms by flowing water downhill through a turbine system to generate electric energy. The Hoover Dam on the Colorado River is 211 m high and generates 4×10^9 kW·h/y. At what rate (in L/s) must water be flowing through the turbines to generate this power? The density of water is 1.00 kg/L. Assume a total efficiency of 90.0 percent in converting the water's potential energy into electrical energy.

Picture the Problem We can relate the energy available from the water in terms of its mass, the vertical distance it has fallen, and the efficiency of the process. Differentiation of this expression with respect to time will yield the rate at which water must pass through its turbines to generate Hoover Dam's annual energy output.

Assuming a total efficiency ε, use the expression for the gravitational potential energy near Earth's surface to express the energy available from the water when it has fallen a distance *h*:

$$E = \varepsilon mgh$$

Differentiate this expression with respect to time to obtain:

$$P = \frac{d}{dt}\left[\varepsilon mgh\right] = \varepsilon gh\frac{dm}{dt} = \varepsilon \rho gh\frac{dV}{dt}$$

Solving for dV/dt yields:

$$\frac{dV}{dt} = \frac{P}{\varepsilon\rho gh} \qquad (1)$$

Using its definition, relate the dam's annual power output to the energy produced:

$$P = \frac{\Delta E}{\Delta t}$$

Substituting for *P* in equation (1) yields:

$$\frac{dV}{dt} = \frac{\Delta E}{\varepsilon\rho gh\Delta t}$$

Substitute numerical values and evaluate dV/dt:

$$\frac{dV}{dt} = \frac{4.00\times10^9\ \text{kW}\cdot\text{h}}{(0.90)(1.00\,\text{kg/L})(9.81\,\text{m/s}^2)(211\,\text{m})\left(365.24\,\text{d}\times\frac{24\,\text{h}}{\text{d}}\right)} = \boxed{2.4\times10^5\ \text{L/s}}$$

Force, Potential Energy, and Equilibrium

20 • Water flows over Victoria Falls, which is 128 m high, at an average rate of 1.4×10^6 kg/s. If half the potential energy of this water were converted into electric energy, how much electric power would be produced by these falls?

Picture the Problem The water going over the falls has gravitational potential energy relative to the base of the falls. As the water falls, the falling water acquires kinetic energy until, at the base of the falls; its energy is entirely kinetic. The rate at which energy is delivered to the base of the falls is given by $P = dW/dt = -dU/dt$.

Express the rate at which energy is being delivered to the base of the falls; remembering that half the potential energy of the water is converted to electric energy:

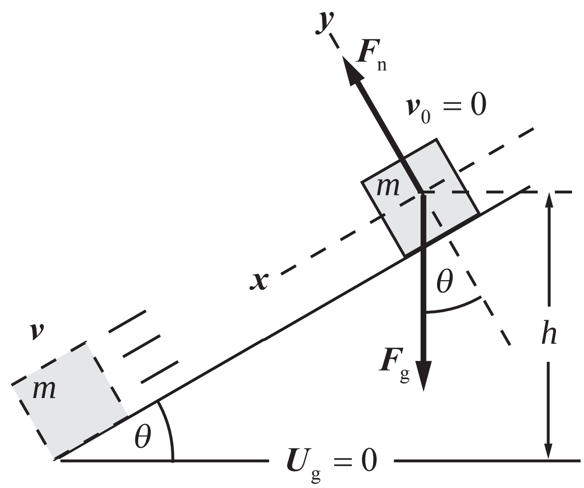
$$P = \frac{dW}{dt} = -\frac{dU}{dt} = -\tfrac{1}{2}\frac{d}{dt}(mgh)$$
$$= -\tfrac{1}{2}gh\frac{dm}{dt}$$

Substitute numerical values and evaluate P:

$$P = -\tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)(-128\,\text{m})\left(1.4\times10^6\ \text{kg/s}\right) = \boxed{0.88\,\text{GW}}$$

21 • A 2.0-kg box slides down a long, frictionless incline of angle 30º. It starts from rest at time $t = 0$ at the top of the incline at a height of 20 m above the ground. (*a*) What is the potential energy of the box relative to the ground at $t = 0$? (*b*) Use Newton's laws to find the distance the box travels during the interval $0.0\text{ s} < t < 1.0\text{ s}$ and its speed at $t = 1.0$ s. (*c*) Find the potential energy and the kinetic energy of the box at $t = 1.0$ s. (*d*) Find the kinetic energy and the speed of the box just as it reaches the ground at the bottom of the incline.

Picture the Problem In the absence of friction, the sum of the potential and kinetic energies of the box remains constant as it slides down the incline. We can use the conservation of the mechanical energy of the system to calculate where the box will be and how fast it will be moving at any given time. We can also use Newton's second law to show that the acceleration of the box is constant and constant-acceleration equations to calculate where the box will be and how fast it will be moving at any given time.



(*a*) Express the gravitational potential energy of the box, relative to the ground, at the top of the incline:

$$U_i = mgh$$

Substitute numerical values and evaluate U_i:

$$U_i = (2.0\,\text{kg})(9.81\,\text{m/s}^2)(20\,\text{m}) = 392\,\text{J} = \boxed{0.39\,\text{kJ}}$$

(*b*) Using a constant-acceleration equation, relate the displacement of the box to its initial speed, acceleration and time-of-travel:

$$\Delta x = v_0 t + \tfrac{1}{2}at^2$$

or, because $v_0 = 0$,

$$\Delta x = \tfrac{1}{2}at^2 \qquad (1)$$

Apply $\sum F_x = ma_x$ to the box as it slides down the incline and solve for its acceleration:

$$F_g \sin\theta = ma$$

or, because $F_g = mg$,

$$mg\sin\theta = ma \Rightarrow a = g\sin\theta$$

Substitute for a in equation (1) to obtain:

$$\Delta x = \tfrac{1}{2}(g\sin\theta)t^2$$

Substitute numerical values and evaluate $\Delta x(t = 1.0\text{ s})$:

$$\Delta x(1.0\,\text{s}) = \tfrac{1}{2}(9.81\,\text{m/s}^2)(\sin 30°)(1.0\,\text{s})^2 = 2.45\,\text{m} = \boxed{2.5\,\text{m}}$$

Using a constant-acceleration equation, relate the speed of the box at any time to its initial speed and acceleration:

$$v = v_0 + at$$

or, because $v_0 = 0$,

$$v = at = g(\sin\theta)t$$

Substitute numerical values and evaluate v(1.0 s):

$$v(1.0\,\text{s}) = (9.81\,\text{m/s}^2)(\sin 30°)(1.0\,\text{s}) = 4.91\,\text{m/s} = \boxed{4.9\,\text{m/s}}$$

(c) The kinetic energy of the box is given by:

$$K = \tfrac{1}{2}mv^2$$

or, because $v = g(\sin\theta)t$,

$$K(t) = \tfrac{1}{2}mg^2(\sin^2\theta)t^2$$

Substitute numerical values and evaluate K(1.0 s):

$$K(1.0\,\text{s}) = \tfrac{1}{2}(2.0\,\text{kg})(9.81\,\text{m/s}^2)^2(\sin^2 30)(1.0\,\text{s})^2 = 24.1\,\text{J} = \boxed{24\,\text{J}}$$

Express the potential energy of the box after it has traveled for 1.0 s in terms of its initial potential energy and its kinetic energy:

$$U = U_\text{i} - K = 392\,\text{J} - 24\,\text{J} = \boxed{0.37\,\text{kJ}}$$

(d) Apply conservation of mechanical energy to the box-Earth system as the box as it slides down the incline:

$$W_\text{ext} = \Delta K + \Delta U = 0$$

or, because $K_\text{i} = U_\text{f} = 0$,

$$K_\text{f} - U_\text{i} = 0 \qquad (2)$$

Solving for K_f yields:

$$K_\text{f} = U_\text{i} = \boxed{0.39\,\text{kJ}}$$

From equation (2) we have:

$$\tfrac{1}{2}mv_\text{f}^2 = U_\text{i} \Rightarrow v_\text{f} = \sqrt{\frac{2U_\text{i}}{m}}$$

Substitute numerical values and evaluate v_f:

$$v_\text{f} = \sqrt{\frac{2(392\,\text{J})}{2.0\,\text{kg}}} = \boxed{20\,\text{m/s}}$$

22 • A constant force F_x = 6.0 N is in the +x direction. (a) Find the potential-energy function $U(x)$ associated with this force if $U(x_0) = 0$. (b) Find a function $U(x)$ such that U(4 .0 m) = 0. (c) Find a function $U(x)$ such that U(6 .0 m) = 14 J.

Picture the Problem The potential energy function $U(x)$ is defined by the equation $U(x) - U(x_0) = -\int_{x_0}^{x} F\,dx.$ We can use the given force function to determine $U(x)$ and then the conditions on $U(x)$ to determine the potential functions that satisfy the given conditions.

(*a*) Use the definition of the potential energy function to find the potential energy function associated with F_x:

$$U(x)=U(x_0)-\int_{x_0}^{x}F_x dx$$
$$=U(x_0)-\int_{x_0}^{x}(6\,\text{N})dx$$
$$=U(x_0)-(6.0\,\text{N})(x-x_0)$$

Because $U(x_0) = 0$:

$$U(x)=\boxed{-(6.0\,\text{N})(x-x_0)}$$

(*b*) Use the result obtained in (*a*) to find $U(x)$ that satisfies the condition that $U(4.0\text{ m}) = 0$:

$$U(4.0\,\text{m})=-(6.0\,\text{N})(4.0\,\text{m}-x_0)$$
$$=0\Rightarrow x_0=4.0\,\text{m}$$

and

$$U(x)=-(6.0\,\text{N})(x-4.0\,\text{m})$$
$$=\boxed{24\,\text{J}-(6.0\,\text{N})x}$$

(*c*) Use the result obtained in (*a*) to find $U(x)$ that satisfies the condition that U(6.0 m) = 14 J:

$$U(6.0\,\text{m})=-(6.0\,\text{N})(6.0\,\text{m}-x_0)$$
$$=14\,\text{J}\Rightarrow x_0=\frac{25}{3}\,\text{m}$$

and

$$U(x)=-(6.0\,\text{N})\left(x-\frac{25}{3.0}\,\text{m}\right)$$
$$=\boxed{50\,\text{J}-(6.0\,\text{N})x}$$

23 • A spring has a force constant of 1.0×10^4 N/m . How far must the spring be stretched for its potential energy to equal (*a*) 50 J, and (*b*) 100 J?

Picture the Problem The potential energy of a stretched or compressed ideal spring U_s is related to its force (stiffness) constant k and stretch or compression Δx by $U_s=\frac{1}{2}kx^2$.

(*a*) Relate the potential energy stored in the spring to the distance it has been stretched:

$$U_s=\tfrac{1}{2}kx^2\Rightarrow x=\sqrt{\frac{2U_s}{k}}$$

Substitute numerical values and evaluate x:

$$\boldsymbol{x}=\sqrt{\frac{2(50\,\text{J})}{1.0\times10^4\,\text{N/m}}}=\boxed{10\,\text{cm}}$$

(*b*) Proceed as in (*a*) with $U_s = 100$ J:

$$x = \sqrt{\frac{2(100\,\text{J})}{1.0\times10^4\ \text{N/m}}} = \boxed{14\ \text{cm}}$$

24 • (*a*) Find the force F_x associated with the potential-energy function $U = Ax^4$, where A is a constant. (*b*) At what value(s) of x does the force equal zero?

Picture the Problem F_x is defined to be the negative of the derivative of the potential-energy function with respect to x, that is, $F_x = -dU/dx$. Consequently, given U as a function of x, we can find F_x by differentiating U with respect to x.

(*a*) Evaluate $F_x = -\dfrac{dU}{dx}$:

$$F_x = -\frac{d}{dx}\left(Ax^4\right) = \boxed{-4Ax^3}$$

(*b*) Set $F_x = 0$ and solve for x to obtain:

$$F_x = 0 \Rightarrow \boxed{x = 0}$$

25 •• **[SSM]** The force F_x is associated with the potential-energy function $U = C/x$, where C is a positive constant. (*a*) Find the force F_x as a function of x. (*b*) Is this force directed toward the origin or away from it in the region $x > 0$? Repeat the question for the region $x < 0$. (*c*) Does the potential energy U increase or decrease as x increases in the region $x > 0$? (*d*) Answer Parts (*b*) and (*c*) where C is a negative constant.

Picture the Problem F_x is defined to be the negative of the derivative of the potential-energy function with respect to x, that is $F_x = -dU/dx$. Consequently, given U as a function of x, we can find F_x by differentiating U with respect to x.

(*a*) Evaluate $F_x = -\dfrac{dU}{dx}$:

$$F_x = -\frac{d}{dx}\left(\frac{C}{x}\right) = \boxed{\frac{C}{x^2}}$$

(*b*) Because $C > 0$, if $x > 0$, F_x is positive and $\vec{F}$ points away from the origin. If $x < 0$, F_x is still positive and $\vec{F}$ points toward the origin.

(*c*) Because U is inversely proportional to x and $C > 0$, $U(x)$ decreases with increasing x.

(*d*) When $C < 0$, if $x > 0$, F_x is negative and $\vec{F}$ points toward the origin. If $x < 0$, F_x is negative and $\vec{F}$ points away from the origin.

Because U is inversely proportional to x and $C < 0$, $U(x)$ becomes less negative as x increases and $U(x)$ increases with increasing x.

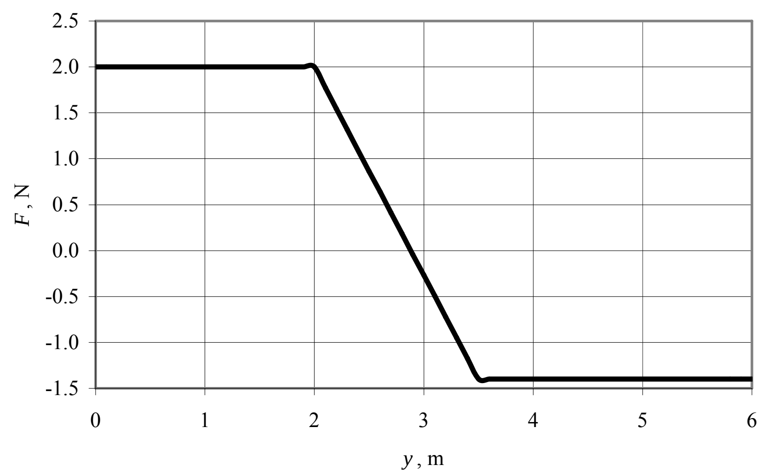
26 •• The force F_y is associated with the potential-energy function $U(y)$. On the potential-energy curve for U versus y, shown in Figure 7-37, the segments AB and CD are straight lines. Plot F_y versus y. Include numerical values, with units, on both axes. These values can be obtained from the U versus y plot.

Picture the Problem F_y is defined to be the negative of the derivative of the potential-energy function with respect to y; that is, $F_y = -dU/dy$. Consequently, we can obtain F_y by examining the slopes of the graph of U as a function of y.

The table to the right summarizes the information we can obtain from Figure 7-37:

	Slope	F_y
Interval	(N)	(N)
A→B	−2	2
B→C	transitional	$2 \rightarrow -1.4$
C→D	1.4	−1.4

The following graph shows F as a function of y:



27 •• The force acting on an object is given by $F_x = a/x^2$. At $x = 5.0$ m, the force is known to point in the $-x$ direction and have a magnitude of 25.0 N. Determine the potential energy associated with this force as a function of x, assuming we assign a reference value of −10.0 J at $x = 2.0$ m for the potential energy.

Picture the Problem F_x is defined to be the negative of the derivative of the potential-energy function with respect to x, i.e. $F_x = -dU/dx$. Consequently, given F as a function of x, we can find U by integrating F_x with respect to x. Applying the condition on $F_{x}x$ will allow us to determine the value of a and using the fact that the potential energy is −10.0 J at $x = 2.00$ m will give us the value of U_0.

Evaluate the integral of F_x with respect to x:

$$U(x) = -\int F_x dx = -\int \frac{a}{x^2} dx = \frac{a}{x} + U_0 \quad (1)$$

Because $F_x(5.0\text{ m}) = -25.0\text{ N}$:

$$\frac{a}{(5.00\text{ m})^2} = -25.0\text{ N}$$

Solving for a yields:

$$a = -625\text{ N}\cdot\text{m}^2$$

Substitute for a in equation (1) to obtain:

$$U(x) = \frac{-625\text{ N}\cdot\text{m}^2}{x} + U_0 \quad (2)$$

Applying the condition $U(2.00\text{ m}) = -10.0\text{ J}$ yields:

$$-10.0\text{ J} = \frac{-625\text{ N}\cdot\text{m}^2}{2.00\text{ m}} + U_0$$

Solve for U_0 to obtain:

$$U_0 = 303\text{ J}$$

Substituting for U_0 in equation (2) yields:

$$U(x) = \boxed{\frac{-625\text{ N}\cdot\text{m}^2}{x} + 303\text{ J}}$$

28 •• The potential energy of an object constrained to the x axis is given by $U(x) = 3x^2 - 2x^3$, where U is in joules and x is in meters. (*a*) Determine the force F_x associated with this potential energy function. (*b*) Assuming no other forces act on the object, at what positions is this object in equilibrium? (*c*) Which of these equilibrium positions are stable and which are unstable?

Picture the Problem F_x is defined to be the negative of the derivative of the potential-energy function with respect to x, that is, $F_x = -dU/dx$. Consequently, given U as a function of x, we can find F_x by differentiating U with respect to x. To determine whether the object is in stable or unstable equilibrium at a given point, we'll evaluate d^2U/dx^2 at the point of interest.

(*a*) Evaluate $F_x = -\dfrac{dU}{dx}$:

$$F_x = -\frac{d}{dx}\left(3x^2 - 2x^3\right) = \boxed{6x(x-1)}$$

(*b*) We know that, at equilibrium, $F_x = 0$:

When $F_x = 0$, $6x(x - 1) = 0$. Therefore, the object is in equilibrium at $\boxed{x = 0 \text{ and } x = 1\text{m.}}$

(*c*) To decide whether the equilibrium at a particular point is stable or unstable, evaluate the 2nd derivative of the potential energy function at the point of interest:

$$\frac{dU}{dx}=\frac{d}{dx}\left(3x^2-2x^3\right)=6x-6x^2$$

and

$$\frac{d^2U}{dx^2}=6-12x$$

Evaluate $\frac{d^2U}{dx^2}$ at $x = 0$:

$$\left.\frac{d^2U}{dx^2}\right|_{x=0}=6>0$$

$$\Rightarrow \boxed{\text{stable equilibrium at } x=0}$$

Evaluate $\frac{d^2U}{dx^2}$ at $x = 1$ m:

$$\left.\frac{d^2U}{dx^2}\right|_{x=1\,\text{m}}=6-12<0$$

$$\Rightarrow \boxed{\text{unstable equilibrium at } x=1\,\text{m}}$$

29 •• [SSM] The potential energy of an object constrained to the x axis is given by $U(x) = 8x^2 - x^4$, where U is in joules and x is in meters. (*a*) Determine the force F_x associated with this potential energy function. (*b*) Assuming no other forces act on the object, at what positions is this object in equilibrium? (*c*) Which of these equilibrium positions are stable and which are unstable?

Picture the Problem F_x is defined to be the negative of the derivative of the potential-energy function with respect to x, that is $F_x=-dU/dx$. Consequently, given U as a function of x, we can find F_x by differentiating U with respect to x. To determine whether the object is in stable or unstable equilibrium at a given point, we'll evaluate d^2U/dx^2 at the point of interest.

(*a*) Evaluate the negative of the derivative of U with respect to x:

$$F_x=-\frac{dU}{dx}=-\frac{d}{dx}\left(8x^2-x^4\right)$$
$$=4x^3-16x=\boxed{4x(x+2)(x-2)}$$

(*b*) The object is in equilibrium wherever $F_{\text{net}}=F_x=0$:

$4x(x+2)(x-2)=0 \Rightarrow$ the equilibrium points are $\boxed{x=-2\,\text{m}, 0, \text{and } 2\,\text{m.}}$

(c) To decide whether the equilibrium at a particular point is stable or unstable, evaluate the 2nd derivative of the potential energy function at the point of interest:

$$\frac{d^2U}{dx^2}=\frac{d}{dx}\left(16x-4x^3\right)=16-12x^2$$

Evaluating d^2U/dx^2 at $x = -2$ m, 0 and $x = 2$ m yields the following results:

x, m	d^2U/dx^2	Equilibrium
−2	−32	Unstable
0	16	Stable
2	−32	Unstable

Remarks: You could also decide whether the equilibrium positions are stable or unstable by plotting *F*(*x*) and examining the curve at the equilibrium positions.

30 •• The net force acting on an object constrained to the x axis is given by $F_x(x) = x^3 - 4x$. (The force is in newtons and x in meters.) Locate the positions of unstable and stable equilibrium. Show that each of these positions is either stable or unstable by calculating the force one millimeter on either side of the locations.

Picture the Problem The equilibrium positions are those values of x for which $F(x) = 0$. Whether the equilibrium positions are stable or unstable depends on whether the signs of the force either side of the equilibrium position are the same (unstable equilibrium) of opposite (stable equilibrium).

Determine the equilibrium locations by setting $F_{\text{net}} = F(x) = 0$:

$F(x) = x^3 - 4x = x(x^2 - 4) = 0$
and the positions of stable and unstable equilibrium are at

$\boxed{x = -2\text{ m}, 0\text{ and }2\text{ m}}$.

Noting that we need only determine whether each value of $F(x)$ is positive or negative, evaluate $F(x)$ at x = −201 mm and x = −199 mm to determine the stability at x = −200 mm … and repeat these calculations at x = −1 mm, 1 mm and x = 199 mm, 201 mm to complete the following table:

x, mm	$F_{x-1\,\text{mm}}$	$F_{x+1\,\text{mm}}$	Equilibrium
−200	< 0	< 0	Unstable
0	> 0	< 0	Stable
200	> 0	> 0	Unstable

Remarks: You can very easily confirm these results by using your graphing calculator to plot *F*(*x*). You could also, of course, find *U*(*x*) from *F*(*x*) and examine it at the equilibrium positions.

31 •• The potential energy of a 4.0-kg object constrained to the x axis is given by $U = 3x^2 - x^3$ for $x \le 3.0$ m and $U = 0$ for $x \ge 3.0$ m, where U is in joules and x is in meters, and the only force acting on this object is the force associated with this potential energy function. (*a*) At what positions is this object in equilibrium? (*b*) Sketch a plot of U versus x. (*c*) Discuss the stability of the equilibrium for the values of x found in Part (*a*). (*d*) If the total mechanical energy of the particle is 12 J, what is its speed at x = 2.0 m?

Picture the Problem F_x is defined to be the negative of the derivative of the potential-energy function with respect to x, that is $F_x = -dU/dx$. Consequently, given U as a function of x, we can find F_x by differentiating U with respect to x. To determine whether the object is in stable or unstable equilibrium at a given point, we can examine the graph of U.

(*a*) Evaluate $F_x = -\dfrac{dU}{dx}$ for $x \le 3.0$ m:

$$F_x = -\frac{d}{dx}\left(3x^2 - x^3\right) = 3x\left(2 - x\right)$$

Set $F_x = 0$ and solve for those values of x for which the 4.0-kg object is in equilibrium:

$3x(2 - x) = 0$

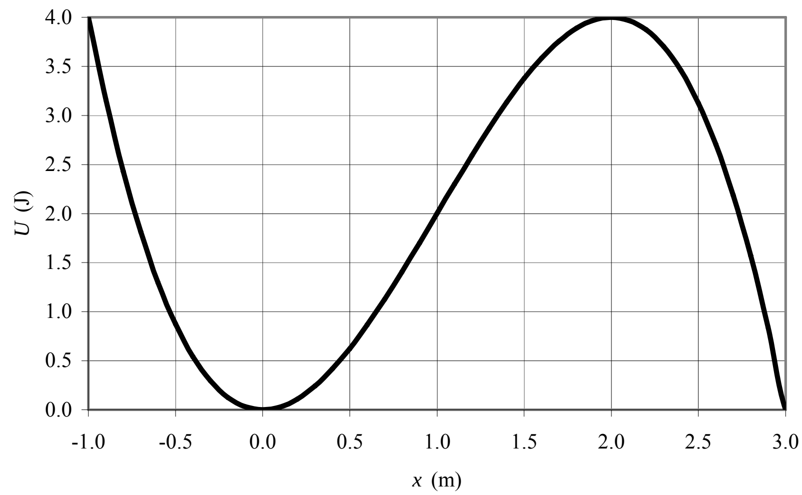
Therefore, the object is in equilibrium at $\boxed{\boldsymbol{x} = 0 \text{ and } \boldsymbol{x} = 2.0\,\text{m}.}$

Because $U = 0$:

$$F_x\left(x \ge 3\,\text{m}\right) = -\frac{dU}{dx} = 0$$

Therefore, the object is in neutral equilibrium for $x \ge 3.0$ m.

(*b*) A graph of $U(x)$ in the interval $-1.0\text{ m} \le x \le 3.0\text{ m}$ follows:



(*c*) From the graph, $U(x)$ is a minimum at $x = 0$ and so the equilibrium is stable at this point

From the graph, $U(x)$ is a maximum at $x = 2.0$ m and so the equilibrium is unstable at this point.

(*d*) Relate the kinetic energy of the object K to its total energy E and its potential energy U:

$$K = \tfrac{1}{2}mv^2 = E - U \Rightarrow v = \sqrt{\frac{2(E-U)}{m}}$$

Substitute numerical values and evaluate $v(2.0\text{ m})$:

$$v(2.0\text{ m}) = \sqrt{\frac{2\left(12\text{ J} - \left(\left(3.0\text{ J/m}^2\right)(2.0\text{ m})^2 - \left(1.0\text{ J/m}^3\right)(2.0\text{ m})^3\right)\right)}{4.0\text{ kg}}} = \boxed{2.0\text{ m/s}}$$

32 •• A force is given by $F_x = Ax^{-3}$, where $A = 8.0\text{ N}\cdot\text{m}^3$. (*a*) For positive values of *x*, does the potential energy associated with this force increase or decrease with increasing *x*? (You can determine the answer to this question by imagining what happens to a particle that is placed at rest at some point *x* and is then released.) (*b*) Find the potential-energy function *U* associated with this force such that *U* approaches zero as *x* approaches infinity. (*c*) Sketch *U* versus *x*.

Picture the Problem F_x is defined to be the negative of the derivative of the potential-energy function with respect to *x*, that is $F_x = -dU/dx$. Consequently, given *F* as a function of *x*, we can find *U* by integrating F_x with respect to *x*.

(*a*) Evaluate the negative of the integral of $F(x)$ with respect to x:

$$U(x) = -\int F(x) = -\int Ax^{-3}dx$$
$$= \frac{1}{2}\frac{A}{x^2} + U_0$$

where U_0 is a constant whose value is determined by conditions on $U(x)$.

For $x > 0$:

$$\boxed{U \text{ decreases as } x \text{ increases}}$$

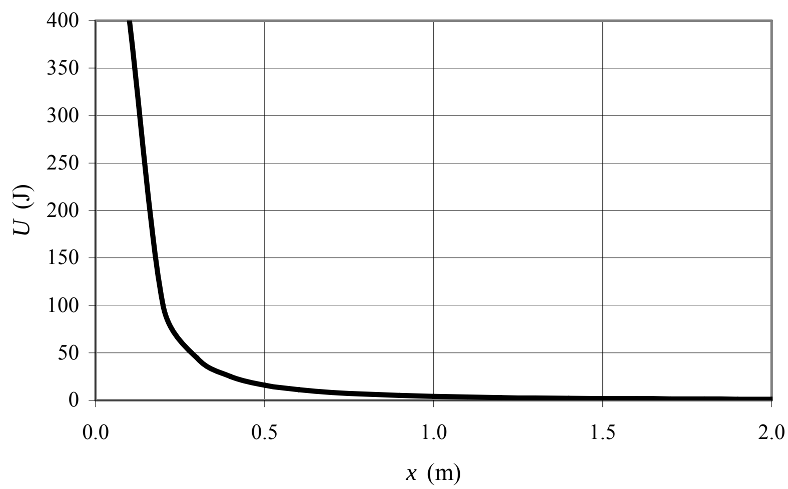
(*b*) As $x \to \infty$, $\frac{1}{2}\frac{A}{x^2} \to 0$. Hence:

$U_0 = 0$

and

$$U(x) = \frac{1}{2}\frac{A}{x^2} = \frac{1}{2}\left(\frac{8.0\,\text{N}\cdot\text{m}^3}{x^2}\right)$$
$$= \boxed{\frac{4.0}{x^2}\text{N}\cdot\text{m}^3}$$

(*c*) The graph of $U(x)$ follows:



33 •• [SSM] A straight rod of negligible mass is mounted on a frictionless pivot, as shown in Figure 7-38. Blocks have masses m_1 and m_2 are attached to the rod at distances ℓ_1 and ℓ_2. (*a*) Write an expression for the gravitational potential energy of the blocks-Earth system as a function of the angle θ made by the rod and the horizontal. (*b*) For what angle θ is this potential energy a minimum? Is the statement "systems tend to move toward a configuration of minimum potential energy" consistent with your result? (*c*) Show that if $m_1\ell_1 = m_2\ell_2$, the potential energy is the same for all values of θ. (When this holds, the system will balance at any angle θ. This result is known as *Archimedes' law of the lever*.)

Picture the Problem The gravitational potential energy of this system of two objects is the sum of their individual potential energies and is dependent on an arbitrary choice of where, or under what condition(s), the gravitational potential energy is zero. The best choice is one that simplifies the mathematical details of the expression for U. In this problem let's choose $U = 0$ where $\theta = 0$.

(*a*) Express U for the 2-object system as the sum of their gravitational potential energies; noting that because the object whose mass is m_2 is above the position we have chosen for $U = 0$, its potential energy is positive while that of the object whose mass is m_1 is negative:

$$U(\theta) = U_1 + U_2 = m_2 g\ell_2 \sin\theta - m_1 g\ell_1 \sin\theta = \boxed{(m_2\ell_2 - m_1\ell_1)g\sin\theta}$$

(*b*) Differentiate U with respect to θ and set this derivative equal to zero to identify extreme values:

$$\frac{dU}{d\theta} = (m_2\ell_2 - m_1\ell_1)g\cos\theta = 0$$

from which we can conclude that $\cos\theta = 0$ and $\theta = \cos^{-1}0$.

To be physically meaningful, $-\pi/2 \le \theta \le \pi/2$. Hence:

$$\theta = \pm\pi/2$$

Express the 2nd derivative of U with respect to θ and evaluate this derivative at $\theta = \pm\pi/2$:

$$\frac{d^2U}{d\theta^2} = -(m_2\ell_2 - m_1\ell_1)g\sin\theta$$

If we assume, in the expression for U that we derived in (*a*), that $m_2\ell_2 - m_1\ell_1 > 0$, then $U(\theta)$ is a sine function and, in the interval of interest,

$$-\pi/2 \le \theta \le \pi/2,$$

takes on its minimum value when $\theta = -\pi/2$:

$$\left.\frac{d^2U}{d\theta^2}\right|_{-\pi/2} > 0 \text{ and}$$

$$\boxed{U \text{ is a minimum at } \theta = -\pi/2}$$

$$\left.\frac{d^2U}{d\theta^2}\right|_{\pi/2} < 0 \text{ and}$$

$$\boxed{U \text{ is a maximum at } \theta = \pi/2}$$

(c) If $m_2\ell_2 = m_1\ell_1$, then:

$$m_1\ell_1 - m_2\ell_2 = 0$$

and

$$\boxed{U = 0 \text{ independent of } \theta.}$$

Remarks: An alternative approach to establishing that *U* is a maximum at $\theta = \pi/2$ is to plot its graph and note that, in the interval of interest, *U* is concave downward with its maximum value at $\theta = \pi/2$. Similarly, it can be shown that *U* is a minimum at $\theta = -\pi/2$ (Part (*b*)).

34 •• An Atwood's machine (Figure 7-39) consists of masses m_1 and m_2, and a pulley of negligible mass and friction. Starting from rest, the speed of the two masses is 4.0 m/s at the end of 3.0 s. At that time, the kinetic energy of the system is 80 J and each mass has moved a distance of 6.0 m. Determine the values of m_1 and m_2.

Picture the Problem In a simple Atwood's machine, the only effect of the pulley is to connect the motions of the two objects on either side of it; that is, it could be replaced by a piece of polished pipe. We can relate the kinetic energy of the rising and falling objects to the mass of the system and to their common speed and relate their accelerations to the sum and difference of their masses … leading to simultaneous equations in m_1 and m_2.

Relate the kinetic energy of the system to the total mass being accelerated:

$$K = \tfrac{1}{2}(m_1 + m_2)v^2 \Rightarrow m_1 + m_2 = \frac{2K}{v^2}$$

Substitute numerical values and evaluate $m_1 + m_2$:

$$m_1 + m_2 = \frac{2(80\,\text{J})}{(4.0\,\text{m/s})^2} = 10.0\,\text{kg} \qquad (1)$$

In Chapter 4, the acceleration of the masses was shown to be:

$$a = \frac{m_1 - m_2}{m_1 + m_2}g$$

Because $v(t) = at$, we can eliminate a in the previous equation to obtain:

$$v(t) = \frac{m_1 - m_2}{m_1 + m_2}gt$$

Solving for $m_1 - m_2$ yields:

$$m_1 - m_2 = \frac{(m_1 + m_2)v(t)}{gt}$$

Substitute numerical values and evaluate $m_1 - m_2$:

$$m_1 - m_2 = \frac{(10\,\text{kg})(4.0\,\text{m/s})}{(9.81\,\text{m/s}^2)(3.0\,\text{s})} = 1.36\,\text{kg} \qquad (2)$$

Solve equations (1) and (2) simultaneously to obtain:

$$m_1 = \boxed{5.7\,\text{kg}} \text{ and } m_2 = \boxed{4.3\,\text{kg}}$$

35 ••• You have designed a novelty desk clock, as shown in Figure 7-40. You are worried that it is not ready for market because the clock itself might be in an unstable equilibrium configuration. You decide to apply your knowledge of potential energies and equilibrium conditions and analyze the situation. The clock (mass *m*) is supported by two light cables running over the two frictionless pulleys of negligible diameter, which are attached to counterweights that each have mass *M*. (*a*) Find the potential energy of the system as a function of the distance *y*. (*b*) Find the value of *y* for which the potential energy of the system is a minimum. (*c*) If the potential energy is a minimum, then the system is in equilibrium. Apply Newton's second law to the clock and show that it is in equilibrium (the forces on it sum to zero) for the value of *y* obtained for Part (*b*). *(d)* Finally, determine whether you are going to be able to market this gadget: is this a point of stable or unstable equilibrium?

Picture the Problem Let *L* be the total length of one cable and the zero of gravitational potential energy be at the top of the pulleys. We can find the value of *y* for which the potential energy of the system is an extremum by differentiating *U*(*y*) with respect to *y* and setting this derivative equal to zero. We can establish that this value corresponds to a minimum by evaluating the second derivative of *U*(*y*) at the point identified by the first derivative. We can apply Newton's second law to the clock to confirm the result we obtain by examining the derivatives of *U*(*y*).

(*a*) Express the potential energy of the system as the sum of the potential energies of the clock and counterweights:

$$U(y)=U_{\text{clock}}(y)+U_{\text{weights}}(y)$$

Substitute for $U_{\text{clock}}(y)$ and $U_{\text{weights}}(y)$ to obtain:

$$U(y)=\boxed{-mgy-2Mg\left(L-\sqrt{y^2+d^2}\right)}$$

(*b*) Differentiate *U*(*y*) with respect to *y*:

$$\frac{dU(y)}{dy}=-\frac{d}{dy}\left[mgy+2Mg\left(L-\sqrt{y^2+d^2}\right)\right]=-\left[mg-2Mg\frac{y}{\sqrt{y^2+d^2}}\right]$$

For extreme values (relative maxima and minima):

$$mg-2Mg\frac{y'}{\sqrt{y'^2+d^2}}=0$$

Solve for y' to obtain:

$$y'=d\sqrt{\frac{m^2}{4M^2-m^2}}$$

Find $\frac{d^2U(y)}{dy^2}$:

$$\frac{d^2U(y)}{dy^2} = -\frac{d}{dy}\left[mg - 2Mg\frac{y}{\sqrt{y^2+d^2}}\right] = \frac{2Mgd^2}{\left(y^2+d^2\right)^{3/2}}$$

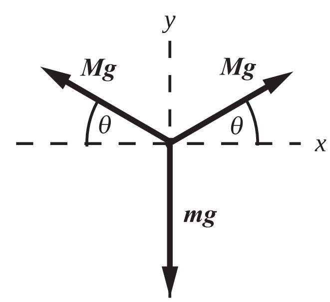
Evaluate $\frac{d^2U(y)}{dy^2}$ at $y = y'$:

$$\left.\frac{d^2U(y)}{dy^2}\right|_{y'} = \left.\frac{2Mgd^2}{\left(y^2+d^2\right)^{3/2}}\right|_{y'} = \frac{2Mgd}{\left(\frac{m^2}{4M^2-m^2}+1\right)^{3/2}} > 0$$

and the potential energy is a minimum at

$$y = \boxed{d\sqrt{\frac{m^2}{4M^2-m^2}}}$$

(*c*) The free-body diagram, showing the magnitudes of the forces acting on the support point just above the clock, is shown to the right:



Apply $\sum F_y = 0$ to this point to obtain:

$$2Mg\sin\theta - mg = 0 \Rightarrow \sin\theta = \frac{m}{2M}$$

Express $\sin\theta$ in terms of y and d:

$$\sin\theta = \frac{y}{\sqrt{y^2+d^2}}$$

Equate the two expressions for $\sin\theta$ to obtain:

$$\frac{m}{2M} = \boxed{\frac{y}{\sqrt{y^2+d^2}}}$$

which is equivalent to the first equation in Part (*b*).

(*d*) This is a point of stable equilibrium. If the clock is displaced downward, θ increases, leading to a larger upward force on the clock. Similarly, if the clock is displaced upward, the net force from the cables decreases. Because of this, the clock will be pulled back toward the equilibrium point if it is displaced away from it.

Remarks: Because we've shown that the potential energy of the system is a minimum at $y = y'$ (i.e., $U(y)$ is concave upward at that point), we can conclude that this point is one of stable equilibrium.

The Conservation of Mechanical Energy

36 • A block of mass *m* on a horizontal frictionless tabletop is pushed against a horizontal spring, compressing it a distance *x*, and the block is then released. The spring propels the block along the tabletop, giving a speed *v*. The same spring is then used to propel a second block of mass 4*m*, giving it a speed 3*v*. What distance was the spring compressed in the second case? Express your answer in terms of *x*.

Picture the Problem The work done in compressing the spring is stored in the spring as potential energy. When the block is released, the energy stored in the spring is transformed into the kinetic energy of the block. Equating these energies will give us a relationship between the compressions of the spring and the speeds of the blocks.

Let the numeral 1 refer to the first case and the numeral 2 to the second case. Relate the compression of the spring in the second case to its potential energy, which equals its initial kinetic energy when released:

$$\begin{aligned}\tfrac{1}{2}kx_2^2 &= \tfrac{1}{2}m_2v_2^2\\ &= \tfrac{1}{2}(4m_1)(3v_1)^2\\ &= 18m_1v_1^2\end{aligned}$$

Relate the compression of the spring in the first case to its potential energy, which equals its initial kinetic energy when released:

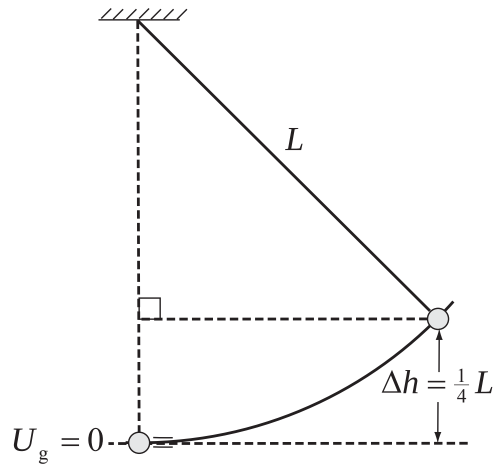
$$\tfrac{1}{2}kx_1^2 = \tfrac{1}{2}m_1v_1^2 \Rightarrow m_1v_1^2 = kx_1^2$$

Substitute for $m_1v_1^2$ to obtain:

$$\tfrac{1}{2}kx_2^2 = 18kx_1^2 \Rightarrow x_2 = \boxed{6x_1}$$

37 • A simple pendulum of length *L* with a bob of mass *m* is pulled aside until the bob is at a height *L*/4 above its equilibrium position. The bob is then released. Find the speed of the bob as it passes through the equilibrium position. Neglect any effects due to air resistance.

Picture the Problem The diagram shows the pendulum bob in its initial position. Let the zero of gravitational potential energy be at the low point of the pendulum's swing, the equilibrium position, and let the system include the pendulum and Earth. We can find the speed of the bob at it passes through the equilibrium position by applying conservation of mechanical energy to the system.



Apply conservation of mechanical energy to the system to obtain:

$W_{ext} = \Delta K + \Delta U$
or, because $W_{ext} = 0$,
$\Delta K + \Delta U = 0$

Because $K_i - U_f = 0$:

$K_f - U_i = 0$

Substituting for K_f and U_i yields:

$\frac{1}{2}mv_f^2 - mg\Delta h = 0 \Rightarrow v_f = \sqrt{2g\Delta h}$

Express Δh in terms of the length L of the pendulum:

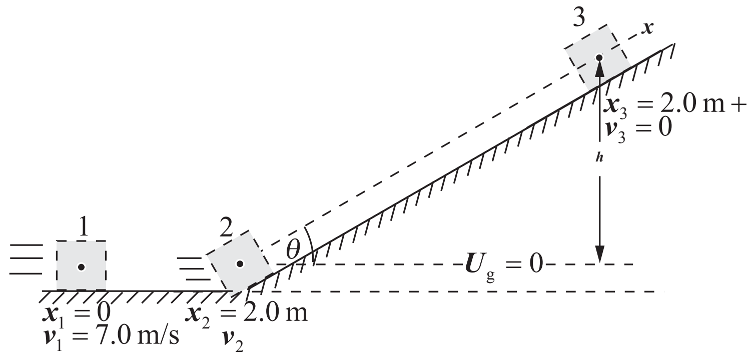
$\Delta h = \frac{L}{4}$

Substitute for Δh in the expression for v_f and simplify to obtain:

$v_f = \boxed{\sqrt{\frac{gL}{2}}}$

38 • A 3.0-kg block slides along a frictionless horizontal surface with a speed of 7.0 m/s (Figure 7-41). After sliding a distance of 2.0 m, the block makes a smooth transition to a frictionless ramp inclined at an angle of 40° to the horizontal. What distance along the ramp does the block slide before coming momentarily to rest?

Picture the Problem The pictorial representation shows the block in its initial, intermediate, and final states. It also shows a choice for $U_g = 0$. Let the system consist of the block, ramp, and Earth. Because the surfaces are frictionless, the initial kinetic energy of the system is equal to its final gravitational potential energy when the block has come to rest on the incline.



Apply conservation of mechanical energy to the system to obtain:

$$W_{ext} = \Delta K + \Delta U$$

or, because $W_{ext} = 0$,

$$\Delta K + \Delta U = 0$$

Because $K_3 = U_1 = 0$:

$$-K_1 + U_3 = 0$$

Substituting for K_1 and U_3 yields:

$$-\tfrac{1}{2}mv_1^2 + mgh = 0 \Rightarrow h = \frac{v_1^2}{2g}$$

where h is the change in elevation of the block as it slides to a momentary stop on the ramp.

Relate the height h to the displacement ℓ of the block along the ramp and the angle the ramp makes with the horizontal:

$$h = \ell \sin\theta$$

Equate the two expressions for h and solve for ℓ to obtain:

$$\ell \sin\theta = \frac{v_1^2}{2g} \Rightarrow \ell = \frac{v_1^2}{2g\sin\theta}$$

Substitute numerical values and evaluate ℓ:

$$\ell = \frac{(7.0\text{ m/s})^2}{2(9.81\text{ m/s}^2)\sin 40°} = \boxed{3.9\text{ m}}$$

39 • The 3.00-kg object in Figure 7-42 is released from rest at a height of 5.00 m on a curved frictionless ramp. At the foot of the ramp is a spring of force constant 400 N/m. The object slides down the ramp and into the spring, compressing it a distance *x* before coming momentarily to rest. (*a*) Find *x*. (*b*) Describe the motion object (if any) after the block momentarily comes to rest?

Picture the Problem Let the system consist of Earth, the block, and the spring. With this choice there are no external forces doing work to change the energy of the system. Let $U_g = 0$ at the elevation of the spring. Then the initial gravitational

potential energy of the 3.00-kg object is transformed into kinetic energy as it slides down the ramp and then, as it compresses the spring, into potential energy stored in the spring.

(*a*) Apply conservation of mechanical energy to the system to relate the distance the spring is compressed to the initial potential energy of the block:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

and, because $\Delta K = 0$,

$$-mgh + \tfrac{1}{2}kx^2 = 0 \Rightarrow x = \sqrt{\frac{2mgh}{k}}$$

Substitute numerical values and evaluate *x*:

$$x = \sqrt{\frac{2(3.00\,\text{kg})(9.81\,\text{m/s}^2)(5.00\,\text{m})}{400\,\text{N/m}}} = \boxed{0.858\,\text{m}}$$

(*b*) The energy stored in the compressed spring will accelerate the block, launching it back up the incline and the block will retrace its path, rising to a height of 5.00 m.

40 • You are designing a game for small children and want to see if the ball's maximum speed is sufficient to require the use of goggles. In your game, a 15.0-g ball is to be shot from a spring gun whose spring has a force constant of 600 N/m. The spring will be compressed 5.00 cm when in use. How fast will the ball be moving as it leaves the gun and how high will the ball go if the gun is aimed vertically upward? What would be your recommendation on the use of goggles?

Picture the Problem With U_g chosen to be zero at the uncompressed level of the spring, the ball's initial gravitational potential energy is negative. Let the system consist of the ball, the spring and gun, and Earth. The difference between the initial potential energy of the spring and the gravitational potential energy of the ball is first converted into the kinetic energy of the ball and then into gravitational potential energy as the ball rises and slows … eventually coming momentarily to rest.

Apply conservation of mechanical energy to the system as the ball leaves the gun to obtain:

$$W_{\text{ext}} = \Delta K + \Delta U_{\text{g}} + \Delta U_{\text{s}} = 0$$

or, because $K_{\text{i}} = U_{\text{s,f}} = U_{\text{g,f}} = 0$,

$$\tfrac{1}{2}mv_{\text{f}}^2 + mgx - \tfrac{1}{2}kx^2 = 0$$

Solving for v_{f} yields:

$$v_{\text{f}} = \sqrt{\left(\frac{k}{m}x - 2g\right)x}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{\left[\left(\frac{600\text{ N/m}}{0.0150\text{ kg}}\right)(0.0500\text{ m}) - 2\left(9.81\text{ m/s}^2\right)\right](0.0500\text{ m})} = \boxed{9.95\text{ m/s}}$$

This initial speed of the ball is fast enough to warrant the use of goggles.

Apply conservation of mechanical energy to the system as the ball rises to its maximum height to obtain:

$$W_{ext} = \Delta K + \Delta U_g + \Delta U_s = 0$$

or, because $\Delta K = U_{s,f} = 0$,

$$mgh + mgx - \tfrac{1}{2}kx^2 = 0$$

where h is the maximum height of the ball.

Solving for h gives:

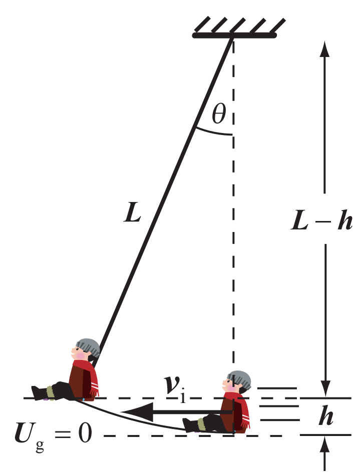
$$h = \frac{kx^2}{2mg} - x$$

Substitute numerical values and evaluate h:

$$h = \frac{(600\text{ N/m})(0.0500\text{ m})^2}{2(0.0150\text{ kg})\left(9.81\text{ m/s}^2\right)} - 0.0500\text{ m}$$
$$= \boxed{5.05\text{ m}}$$

41 • A 16-kg child on a 6.0-m-long playground swing moves with a speed of 3.4 m/s when the swing seat passes through its lowest point. What is the angle that the swing makes with the vertical when the swing is at its highest point? Assume that the effects due to air resistance are negligible, and assume that the child is not pumping the swing.

Picture the Problem Let the system consist of Earth and the child. Then $W_{ext} = 0$. Choose $U_g = 0$ at the child's lowest point as shown in the diagram to the right. Then the child's initial energy is entirely kinetic and its energy when it is at its highest point is entirely gravitational potential. We can determine h from conservation of mechanical energy and then use trigonometry to determine θ.



Using the diagram, relate θ to h and L:

$$\theta = \cos^{-1}\left(\frac{L-h}{L}\right) = \cos^{-1}\left(1 - \frac{h}{L}\right) \quad (1)$$

Apply conservation of mechanical energy to the system to obtain:

$$W_{ext} = \Delta K + \Delta U = 0$$

or, because $K_f = U_{g,i} = 0$,

$$-K_i + U_{g,f} = 0$$

Substituting for K_i and $U_{g,f}$ yields:

$$-\tfrac{1}{2}mv_i^2 + mgh = 0 \Rightarrow h = \frac{v_i^2}{2g}$$

Substitute for h in equation (1) to obtain:

$$\theta = \cos^{-1}\left(1 - \frac{v_i^2}{2gL}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \cos^{-1}\left(1 - \frac{(3.4\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)(6.0\,\text{m})}\right) = \boxed{26°}$$

42 •• The system shown in Figure 7-44 is initially at rest when the lower string is cut. Find the speed of the objects when they are momentarily at the same height. The frictionless pulley has negligible mass.

Picture the Problem Let the system include the two objects and Earth. Then $W_{ext} = 0$. Choose $U_g = 0$ at the elevation at which the two objects meet. With this choice, the initial potential energy of the 3.0-kg object is positive and that of the 2.0-kg object is negative. Their sum, however, is positive. Given our choice for $U_g = 0$, this initial potential energy is transformed entirely into kinetic energy.

Apply conservation of mechanical energy to the system to obtain:

$$W_{ext} = \Delta K + \Delta U_g = 0$$

or, because $W_{ext} = 0$,

$$\Delta K = -\Delta U_g$$

Noting that m represents the sum of the masses of the objects as they are both moving in the final state, substitute for ΔK:

$$\tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_i^2 = -\Delta U_g$$

or, because $v_i = 0$,

$$\tfrac{1}{2}mv_f^2 = -\Delta U_g \Rightarrow v_f = \sqrt{\frac{-2\Delta U_g}{m}}$$

ΔU_g is given by:

$$\Delta U_g = U_{g,f} - U_{g,i} = 0 - (m_3 - m_2)gh$$

Substitute for ΔU_g to obtain:

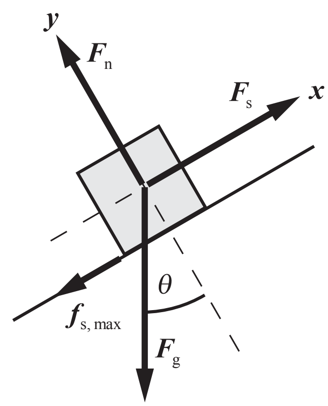
$$v_f = \sqrt{\frac{2(m_3 - m_2)gh}{m}}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{\frac{2(3.0\,\text{kg} - 2.0\,\text{kg})(0.50\,\text{m})(9.81\,\text{m/s}^2)}{3.0\,\text{kg} + 2.0\,\text{kg}}} = \boxed{1.4\,\text{m/s}}$$

43 •• A block of mass *m* rests on an inclined plane (Figure 7-44). The coefficient of static friction between the block and the plane is μ_s. A gradually increasing force is pulling down on the spring (force constant *k*). Find the potential energy *U* of the spring (in terms of the given symbols) at the moment the block begins to move.

Picture the Problem F_s is the force exerted by the spring and, because the block is on the verge of sliding, $f_s = f_{s,max}$. We can use Newton's second law, under equilibrium conditions, to express the elongation of the spring as a function of *m*, *k* and θ and then substitute in the expression for the potential energy stored in a stretched or compressed spring.



Express the potential energy of the spring when the block is about to move:

$$U = \tfrac{1}{2}kx^2$$

Apply $\sum \vec{F} = m\vec{a}$, under equilibrium conditions, to the block:

$$\sum F_x = F_s - f_{s,max} - mg\sin\theta = 0$$

and

$$\sum F_y = F_n - mg\cos\theta = 0$$

Using $f_{s,\,max} = \mu_s F_n$ and $F_s = kx$, eliminate $f_{s,\,max}$ and F_s from the *x* equation and solve for *x*:

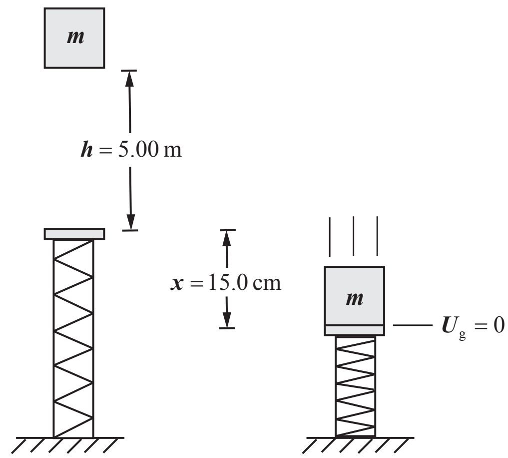
$$x = \frac{mg(\sin\theta + \mu_s\cos\theta)}{k}$$

Substitute for *x* in the expression for *U* and simplify to obtain:

$$U = \tfrac{1}{2}k\left[\frac{mg(\sin\theta + \mu_s\cos\theta)}{k}\right]^2 = \boxed{\frac{[mg(\sin\theta + \mu_s\cos\theta)]^2}{2k}}$$

44 •• A 2.40-kg block is dropped onto a spring and platform (Figure 7-45) of negligible mass. The block is released a distance of 5.00 m above the platform. When the block is momentary at rest, the spring is compressed by 25.0 cm. Find the speed of the block when the compression of the spring is only 15.0 cm

Picture the Problem Let the system include the block, the spring, and Earth. Let $U_g = 0$ where the spring is compressed 15.0 cm. Then the mechanical energy when the compression of the spring is 15.0 cm will be partially kinetic and partially stored in the spring. We can use conservation of mechanical energy to relate the initial potential energy of the system to the energy stored in the spring and the kinetic energy of block when it has compressed the spring 15.0 cm.



Apply conservation of mechanical energy to the system to obtain:

$$W_{ext} = \Delta U + \Delta K = 0$$

or

$$U_{g,f} - U_{g,i} + U_{s,f} - U_{s,i} + K_f - K_i = 0$$

Because $U_{g,f} = U_{s,i} = K_i = 0$:

$$-U_{g,i} + U_{s,f} + K_f = 0$$

Substitute to obtain:

$$-mg(h+x) + \tfrac{1}{2}kx^2 + \tfrac{1}{2}mv^2 = 0$$

Solving for v yields:

$$v = \sqrt{2g(h+x) - \frac{kx^2}{m}}$$

The spring's force constant is given by:

$$k = \frac{w_{block}}{\Delta x} = \frac{mg}{\Delta x}$$

where Δx is the compression of the spring when the block is momentarily at rest.

Substituting for k and simplifying gives:

$$v = \sqrt{2g(h+x) - \frac{mgx^2}{m\Delta x}}$$

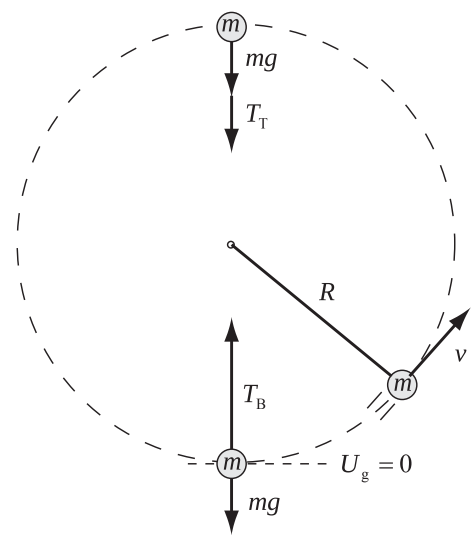
$$= \sqrt{g\left(2(h+x) - \frac{x^2}{\Delta x}\right)}$$

Substitute numerical values and evaluate v:

$$v=\sqrt{\left(9.81\,\text{m/s}^2\right)\left[2\left(5.00\,\text{m}+0.150\,\text{m}\right)-\frac{\left(0.150\,\text{m}\right)^2}{0.250\,\text{m}}\right]}=\boxed{10.0\,\text{m/s}}$$

45 •• **[SSM]** A ball at the end of a string moves in a vertical circle with constant mechanical energy E. What is the difference between the tension at the bottom of the circle and the tension at the top?

Picture the Problem The diagram represents the ball traveling in a circular path with constant energy. U_g has been chosen to be zero at the lowest point on the circle and the superimposed free-body diagrams show the forces acting on the ball at the top (T) and bottom (B) of the circular path. We'll apply Newton's second law to the ball at the top and bottom of its path to obtain a relationship between T_T and T_B and conservation of mechanical energy to relate the speeds of the ball at these two locations.



Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the ball at the bottom of the circle and solve for T_B:

$$T_B - mg = m\frac{v_B^2}{R}$$

and

$$T_B = mg + m\frac{v_B^2}{R} \qquad (1)$$

Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the ball at the top of the circle and solve for TT:

$$T_T + mg = m\frac{v_T^2}{R}$$

and

$$T_T = -mg + m\frac{v_T^2}{R} \qquad (2)$$

Subtract equation (2) from equation (1) to obtain:

$$T_B - T_T = mg + m\frac{v_B^2}{R} - \left(-mg + m\frac{v_T^2}{R}\right) = m\frac{v_B^2}{R} - m\frac{v_T^2}{R} + 2mg \qquad (3)$$

Using conservation of mechanical energy, relate the energy of the ball at the bottom of its path to its mechanical energy at the top of the circle:

$$\tfrac{1}{2}mv_B^2 = \tfrac{1}{2}mv_T^2 + mg(2R)$$

or

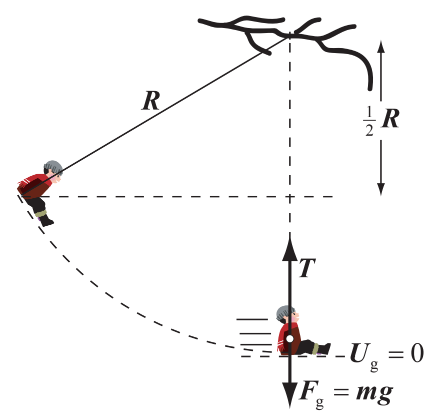
$$m\frac{v_B^2}{R} - m\frac{v_T^2}{R} = 4mg$$

Substituting in equation (3) yields:

$$T_B - T_T = \boxed{6mg}$$

46 •• A girl of mass m is taking a picnic lunch to her grandmother. She ties a rope of length R to a tree branch over a creek and starts to swing from rest at a point that is a distance $R/2$ lower than the branch. What is the minimum breaking tension for the rope if it is not to break and drop the girl into the creek?

Picture the Problem Let the system consist of the girl and Earth and let $U_g = 0$ at the lowest point in the girl's swing. We can apply conservation of mechanical energy to the system to relate the girl's speed v to R. The force diagram shows the forces acting on the girl at the low point of her swing. Applying Newton's second law to her will allow us to establish the relationship between the tension T and her speed.



Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the girl at her lowest point and solve for T:

$$T - mg = m\frac{v^2}{R}$$

and

$$T = mg + m\frac{v^2}{R} \qquad (1)$$

Apply conservation of mechanical energy to the system to obtain:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

Substituting for K_f and U_i yields:

$$K_f - U_i = 0$$

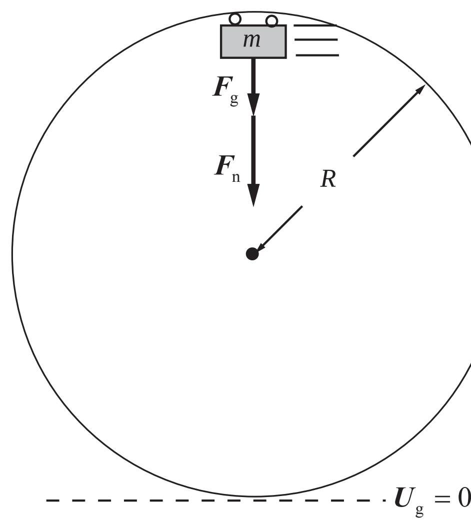
$$\tfrac{1}{2}mv^2 - mg\frac{R}{2} = 0 \Rightarrow \frac{v^2}{R} = g$$

Substitute for v^2/R in equation (1) and simplify to obtain:

$$T = mg + mg = \boxed{2mg}$$

47 •• A 1500-kg roller coaster car starts from rest a height H = 23.0 m (Figure 7-46) above the bottom of a 15.0-m-diameter loop. If friction is negligible, determine the downward force of the rails on the car when the upside-down car is at the top of the loop.

Picture the Problem Let the system include the car, the track, and Earth. The pictorial representation shows the forces acting on the car when it is upside down at the top of the loop. Choose U_g = 0 at the bottom of the loop. We can express F_n in terms of v and R by apply Newton's second law to the car and then obtain a second expression in these same variables by applying conservation of mechanical energy to the system. The simultaneous solution of these equations will yield an expression for F_n in terms of known quantities.



Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the car at the top of the circle and solve for F_n:

$$F_n + mg = m\frac{v^2}{R}$$

and

$$F_n = m\frac{v^2}{R} - mg \qquad (1)$$

Using conservation of mechanical energy, relate the energy of the car at the beginning of its motion to its energy when it is at the top of the loop:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

or, because K_i = 0,

$$K_f + U_f - U_i = 0$$

Substitute for K_f, U_f, and U_i to obtain:

$$\tfrac{1}{2}mv^2 + mg(2R) - mgH = 0$$

Solving for $m\dfrac{v^2}{R}$ yields:

$$m\frac{v^2}{R} = 2mg\left(\frac{H}{R} - 2\right) \qquad (2)$$

Substitute equation (2) in equation (1) to obtain:

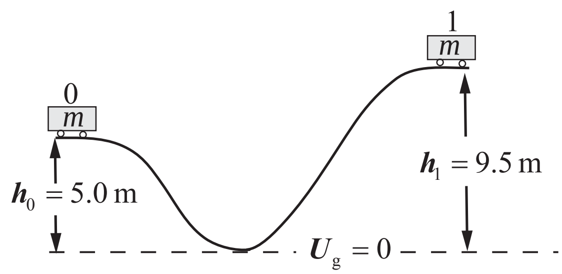
$$F_n = 2mg\left(\frac{H}{R} - 2\right) - mg$$
$$= mg\left(\frac{2H}{R} - 5\right)$$

Substitute numerical values and evaluate F_n:

$$F_n = (1500\,\text{kg})(9.81\,\text{m/s}^2)\left[\frac{2(23.0\,\text{m})}{7.50\,\text{m}} - 5\right] = \boxed{16.7\,\text{kN}}$$

48 •• A single roller-coaster car is moving with speed v_0 on the first section of track when it descends a 5.0-m-deep valley, then climbs to the top of a hill that is 4.5 m above the first section of track. Assume any effects of friction or of air resistance are negligible. (*a*) What is the minimum speed v_0 required if the car is to travel beyond the top of the hill? (*b*) Can we affect this speed by changing the depth of the valley to make the coaster pick up more speed at the bottom? Explain.

Picture the Problem Let the system include the roller coaster, the track, and Earth and denote the starting position with the numeral 0 and the top of the second hill with the numeral 1. We can use the work-energy theorem to relate the energies of the coaster at its initial and final positions. Let *m* be the mass of the roller coaster.



(*a*) Use conservation of mechanical energy to relate the work done by external forces to the change in the energy of the system:

$$W_{ext} = \Delta E_{sys} = \Delta K + \Delta U$$

Because the track is frictionless, $W_{ext} = 0$:

$$\Delta K + \Delta U = 0$$
and
$$K_1 - K_0 + U_1 - U_0 = 0$$

Substitute to obtain:

$$\tfrac{1}{2}mv_1^2 - \tfrac{1}{2}mv_0^2 + mgh_1 - mgh_0 = 0$$

Solving for v_0 yields:

$$v_0 = \sqrt{v_1^2 + 2g(h_1 - h_0)}$$

If the coaster just makes it to the top of the second hill, $v_1 = 0$ and:

$$v_0 = \sqrt{2g(h_1 - h_0)}$$

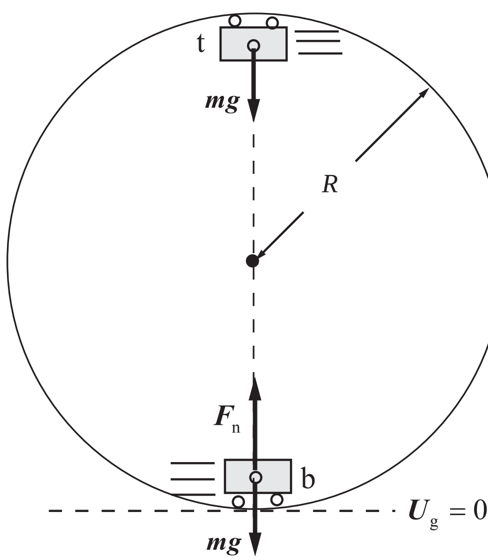
Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{2(9.81\,\text{m/s}^2)(9.5\,\text{m} - 5.0\,\text{m})} = \boxed{9.4\,\text{m/s}}$$

(*b*) No. Note that the required speed depends only on the difference in the heights of the two hills.

49 •• The Gravitron single-car roller coaster consists of a single loop-the-loop. The car is initially pushed, giving it just the right mechanical energy so the riders on the coaster will feel "weightless" when they pass through the top of the circular arc. How heavy will they feel when they pass through the bottom of the arc (that is, what is the normal force pressing up on them when they are at the bottom of the loop)? Express the answer as a multiple of *mg* (their actual weight). Assume any effects of friction or of air resistance are negligible.

Picture the Problem Let the radius of the loop be *R* and the mass of one of the riders be *m*. At the top of the loop, the centripetal force on her is her weight (the force of gravity). The two forces acting on her at the bottom of the loop are the normal force exerted by the seat of the car, pushing up, and the force of gravity, pulling down. We can apply Newton's second law to her at both the top and bottom of the loop to relate the speeds at those locations to *m* and *R* and, at *b*, to *F*, and then use conservation of mechanical energy to relate v_t and v_b.



Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the rider at the bottom of the circular arc:

$$F_n - mg = m\frac{v_b^2}{R} \Rightarrow F_n = mg + m\frac{v_b^2}{R} \quad (1)$$

Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the rider at the top of the circular arc:

$$mg = m\frac{v_{\text{t}}^2}{R} \Rightarrow v_{\text{t}}^2 = gR$$

Apply conservation of mechanical energy to the system to obtain:

$$K_{\text{b}} - K_{\text{t}} + U_{\text{b}} - U_{\text{t}} = 0$$

or, because $U_{\text{b}} = 0$,

$$K_{\text{b}} - K_{\text{t}} - U_{\text{t}} = 0$$

Substitute for K_{b}, K_{t}, and U_{t} to obtain:

$$\tfrac{1}{2}mv_{\text{b}}^2 - \tfrac{1}{2}mv_{\text{t}}^2 - 2mgR = 0$$

Solving for v_{b}^2 yields:

$$v_{\text{b}}^2 = 5gR$$

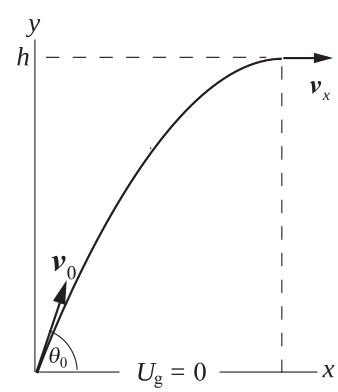
Substitute for v_{b}^2 in equation (1) and simplify to obtain:

$$F_{\text{n}} = mg + m\frac{5gR}{R} = \boxed{6mg}$$

That is, the rider will feel six times heavier than her normal weight.

50 •• A stone is thrown upward at an angle of 53° above the horizontal. Its maximum height above the release point is 24 m. What was the stone's initial speed? Assume any effects of air resistance are negligible.

Picture the Problem Let the system consist of the stone and Earth and ignore the influence of air resistance. Then $W_{\text{ext}} = 0$. Choose $U_{\text{g}} = 0$ as shown in the figure. Apply conservation of mechanical energy to describe the energy transformations as the stone rises to the highest point of its trajectory.



Apply conservation of mechanical energy to the system:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

and

$$K_1 - K_0 + U_1 - U_0 = 0$$

Because $U_0 = 0$:

$$K_1 - K_0 + U_1 = 0$$

Substitute for the kinetic and potential energies yields:

$$\tfrac{1}{2}mv_x^2 - \tfrac{1}{2}mv_0^2 + mgh = 0$$

In the absence of air resistance, the horizontal component of $\vec{v}$ is constant and equal to $v_x = v_0 \cos\theta$:

$$\tfrac{1}{2}m(v_0 \cos\theta)^2 - \tfrac{1}{2}mv_0^2 + mgh = 0$$

Solving for v_0 gives:

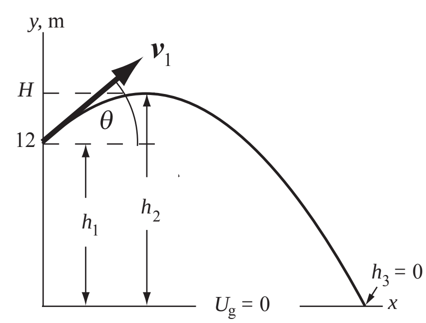
$$v_0 = \sqrt{\frac{2gh}{1-\cos^2\theta}}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{\frac{2(9.81\,\text{m/s}^2)(24\,\text{m})}{1-\cos^2 53°}} = \boxed{27\,\text{m/s}}$$

51 •• A 0.17-kg baseball is launched from the roof of a building 12 m above the ground. Its initial velocity is 30 m/s at 40° above the horizontal. Assume any effects of air resistance are negligible. (*a*) What is the maximum height above the ground the ball reaches? (*b*) What is the speed of the ball as it strikes the ground?

Picture the Problem The figure shows the ball being thrown from the roof of the building. Let the system consist of the ball and Earth. Then $W_{\text{ext}} = 0$. Choose $U_g = 0$ at ground level. We can use conservation of mechanical energy to determine the maximum height of the ball and its speed at impact with the ground.



(*a*) Apply conservation of mechanical energy to obtain:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

or

$$K_2 - K_1 + U_2 - U_1 = 0$$

Substitute for the energies to obtain:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 + mgh_2 - mgh_1 = 0$$

Note that, at point 2, the ball is moving horizontally and:

$$v_2 = v_1 \cos\theta$$

Substitute for v_2 and h_2 to obtain:

$$\tfrac{1}{2}m(v_1 \cos\theta)^2 - \tfrac{1}{2}mv_1^2 + mgH - mgh_1 = 0$$

Solving for H gives:

$$H = h_1 - \frac{v^2}{2g}\left(\cos^2\theta - 1\right)$$

Substitute numerical values and evaluate H:

$$H = 12\,\text{m} - \frac{(30\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)}(\cos^2 40° - 1)$$
$$= \boxed{31\,\text{m}}$$

(*b*) Apply conservation of mechanical energy to the system to relate the initial mechanical energy of the ball to its just-before-impact energy:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

or, because $U_3 = 0$,

$$K_3 - K_1 - U_1 = 0$$

Substituting for K_3, K_1, and U_1 yields:

$$\tfrac{1}{2}mv_3^2 - \tfrac{1}{2}mv_1^2 - mgh_1 = 0$$

Solve for v_3 to obtain:

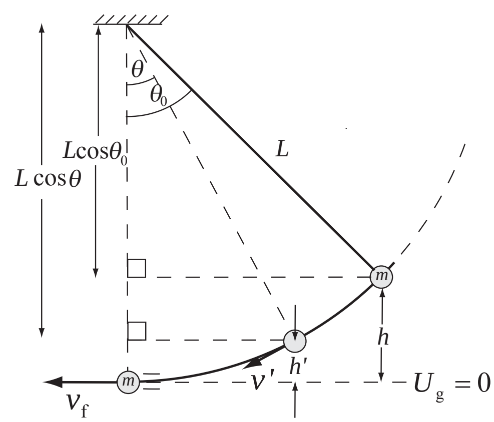
$$v_3 = \sqrt{v_1^2 + 2gh_1}$$

Substitute numerical values and evaluate v_3:

$$v_3 = \sqrt{(30\,\text{m/s})^2 + 2(9.81\,\text{m/s}^2)(12\,\text{m})}$$
$$= \boxed{34\,\text{m/s}}$$

52 •• An 80-cm-long pendulum with a 0.60-kg bob is released from rest at an initial angle of θ_0 with the vertical. At the bottom of the swing, the speed of the bob is 2.8 m/s. (*a*) What is θ_0? (*b*) What angle does the pendulum make with the vertical when the speed of the bob is 1.4 m/s? Is this angle equal to $\frac{1}{2}\theta_0$? Explain why or why not.

Picture the Problem The figure shows the pendulum bob in its release position and in the two positions in which it is in motion with the given speeds. Let the system consist of the pendulum and Earth and choose $U_g = 0$ at the low point of the swing. We can apply conservation of mechanical energy to relate the two angles of interest to the speeds of the bob at the intermediate and low points of its trajectory.



(*a*) Apply conservation of mechanical energy to the system to obtain:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0.$$

Because $K_i = U_f = 0$:

$$K_f - U_i = 0 \qquad (1)$$

Refer to the pictorial representation to see that U_i is given by:

$$U_i = mgh = mgL(1-\cos\theta_0)$$

Substitute for K_f and U_i in equation (1) to obtain:

$$\tfrac{1}{2}mv_f^2 - mgL(1-\cos\theta_0) = 0$$

Solving for θ_0 yields:

$$\theta_0 = \cos^{-1}\left(1-\frac{v^2}{2gL}\right)$$

Substitute numerical values and evaluate θ_0:

$$\theta_0 = \cos^{-1}\left[1-\frac{(2.8\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)(0.80\,\text{m})}\right] = \boxed{60°}$$

(*b*) Letting primed quantities describe the indicated location, use conservation of mechanical energy to obtain :

$$K_f' - K_i + U_f' - U_i = 0$$

Because $K_i = 0$:

$$K_f' + U_f' - U_i = 0$$

Refer to the pictorial representation to see that U_f' is given by:

$$U_f' = mgh' = mgL(1-\cos\theta)$$

Substitute for K_f', U_f' and U_i :

$$\tfrac{1}{2}m(v_f')^2 + mgL(1-\cos\theta) - mgL(1-\cos\theta_0) = 0$$

Solving for θ yields :

$$\theta = \cos^{-1}\left[\frac{(v_f')^2}{2gL} + \cos\theta_0\right]$$

Substitute numerical values and evaluate θ:

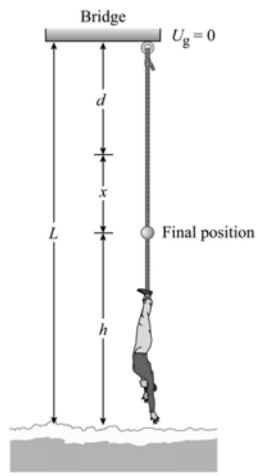
$$\theta = \cos^{-1}\left[\frac{(1.4\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)(0.80\,\text{m})} + \cos 60°\right] = \boxed{51°}$$

No. The change in gravitational potential energy is linearly dependent on the cosine of the angle rather than on the angle itself.

53 •• The Royal Gorge bridge over the Arkansas River is 310 m above the river. A 60-kg bungee jumper has an elastic cord with an unstressed length of 50 m attached to her feet. Assume that, like an ideal spring, the cord is massless and

provides a linear restoring force when stretched. The jumper leaps, and at her lowest point she barely touches the water. After numerous ascents and descents, she comes to rest at a height *h* above the water. Model the jumper as a point particle and assume that any effects of air resistance are negligible. (*a*) Find *h*. (*b*) Find the maximum speed of the jumper.

Picture the Problem Choose $U_g = 0$ at the bridge and let the system be Earth, the jumper and the bungee cord. Then $W_{ext} = 0$. We can use conservation of mechanical energy to relate her initial and final gravitational potential energies to the energy stored in the stretched bungee cord U_s. In Part (*b*), we'll use a similar strategy but include a kinetic energy term because we are interested in finding her maximum speed.



(*a*) Express her final height *h* above the water in terms of *L*, *d* and the distance *x* the bungee cord has stretched:

$$h = L - d - x \qquad (1)$$

Use conservation of mechanical energy to relate her gravitational potential energy as she just touches the water to the energy stored in the stretched bungee cord:

$$W_{ext} = \Delta K + \Delta U = 0$$

Because $\Delta K = 0$ and $\Delta U = \Delta U_g + \Delta U_s$:

$$-mgL + \tfrac{1}{2}ks^2 = 0 \Rightarrow k = \frac{2mgL}{s^2}$$

where *s* is the maximum distance the bungee cord has stretched.

Find the maximum distance the bungee cord stretches:

$s = 310\text{ m} - 50\text{ m} = 260\text{ m}$.

Substitute numerical values and evaluate *k*:

$$k = \frac{2(60\,\text{kg})(9.81\,\text{m/s}^2)(310\,\text{m})}{(260\,\text{m})^2} = 5.40\,\text{N/m}$$

Express the relationship between the forces acting on her when she has finally come to rest x:

$$F_{net} = kx - mg = 0 \Rightarrow x = \frac{mg}{k}$$

Substitute numerical values and evaluate x:

$$x = \frac{(60\,\text{kg})(9.81\,\text{m/s}^2)}{5.40\,\text{N/m}} = 109\,\text{m}$$

Substitute in equation (1) and evaluate h:

$$h = 310\,\text{m} - 50\,\text{m} - 109\,\text{m} = 151\,\text{m} = \boxed{0.15\,\text{km}}$$

(b) Using conservation of mechanical energy, express her total energy E:

$$E = K + U_g + U_s = E_i = 0$$

Because v is a maximum when K is a maximum, solve for K to obtain:

$$K = -U_g - U_s = mg(d + x) - \tfrac{1}{2}kx^2 \qquad (2)$$

Use the condition for an extreme value to obtain:

$$\frac{dK}{dx} = mg - kx = 0 \Rightarrow x = \frac{mg}{k}$$

Substitute numerical values and evaluate x:

$$\boldsymbol{x} = \frac{(60\,\text{kg})(9.81\,\text{m/s}^2)}{5.40\,\text{N/m}} = 109\,\text{m}$$

From equation (2) we have:

$$\tfrac{1}{2}mv^2 = mg(d + x) - \tfrac{1}{2}kx^2$$

Solve for v to obtain:

$$v = \sqrt{2g(d + x) - \frac{kx^2}{m}}$$

Substitute numerical values and evaluate v for x = 109 m:

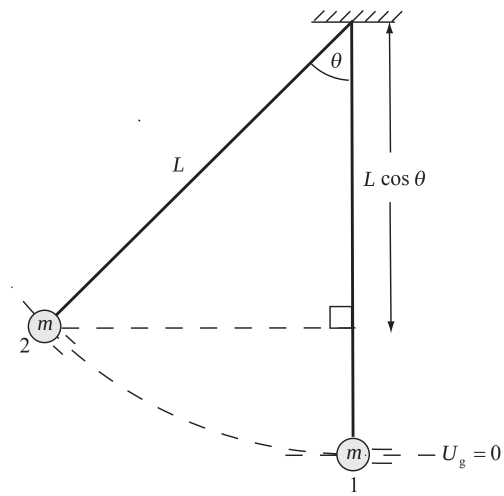
$$v = \sqrt{2(9.81\,\text{m/s}^2)(50\,\text{m} + 109\,\text{m}) - \frac{(5.4\,\text{N/m})(109\,\text{m})^2}{60\,\text{kg}}} = \boxed{45\,\text{m/s}}$$

Because $\dfrac{d^2K}{dx^2} = -k < 0$, x = 109 m corresponds to K_{max} and so v is a maximum.

54 •• A pendulum consists of a 2.0-kg bob attached to a light 3.0-m-long string. While hanging at rest with the string vertical, the bob is struck a sharp horizontal blow, giving it a horizontal velocity of 4.5 m/s. At the instant the string

makes an angle of 30° with the vertical, what is (*a*) the speed, (*b*) the gravitational potential energy (relative to its value is at the lowest point), and (*c*) the tension in the string? (*d*) What is the angle of the string with the vertical when the bob reaches its greatest height?

Picture the Problem Let the system be Earth and the pendulum bob. Then $W_{ext} = 0$. Choose $U_g = 0$ at the low point of the bob's swing and apply conservation of mechanical energy to the system. When the bob reaches the 30° position its energy will be partially kinetic and partially potential. When it reaches its maximum height, its energy will be entirely potential. Applying Newton's second law will allow us to express the tension in the string as a function of the bob's speed and its angular position.



(*a*) Apply conservation of mechanical energy to relate the energies of the bob at points 1 and 2:

$$W_{ext} = \Delta K + \Delta U = 0$$

or

$$K_2 - K_1 + U_2 - U_1 = 0$$

Because $U_1 = 0$:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 + U_2 = 0 \qquad (1)$$

The potential energy of the system when the bob is at point 2 is given by:

$$U_2 = mgL(1 - \cos\theta)$$

Substitute for U_2 in equation (1) to obtain:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 + mgL(1 - \cos\theta) = 0$$

Solving for v_2 yields:

$$v_2 = \sqrt{v_1^2 - 2gL(1 - \cos\theta)}$$

Substitute numerical values and evaluate v_2:

$$v_2 = \sqrt{(4.5\,\text{m/s})^2 - 2(9.81\,\text{m/s}^2)(3.0\,\text{m})(1 - \cos 30°)} = 3.52\,\text{m/s} = \boxed{3.5\,\text{m/s}}$$

(*b*) From (*a*) we have:

$$U_2 = mgL(1 - \cos\theta)$$

Substitute numerical values and evaluate U_2:

$$U_2 = (2.0\,\text{kg})(9.81\,\text{m/s}^2)(3.0\,\text{m})(1-\cos 30°) = \boxed{7.9\,\text{J}}$$

(*c*) Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the bob to obtain:

$$T - mg\cos\theta = m\frac{v_2^2}{L}$$

Solving for T yields:

$$T = m\left(g\cos\theta + \frac{v_2^2}{L}\right)$$

Substitute numerical values and evaluate T:

$$T = (2.0\,\text{kg})\left[(9.81\,\text{m/s}^2)\cos 30° + \frac{(3.52\,\text{m/s})^2}{3.0\,\text{m}}\right] = \boxed{25\,\text{N}}$$

(*d*) When the bob reaches its greatest height:

$$U = U_{\max} = mgL(1-\cos\theta_{\max})$$

and

$$-K_1 + U_{\max} = 0$$

Substitute for K_1 and $U_{\max}$:

$$-\tfrac{1}{2}mv_1^2 + mgL(1-\cos\theta_{\max}) = 0$$

Solve for $\theta_{\max}$ to obtain:

$$\theta_{\max} = \cos^{-1}\left(1 - \frac{v_1^2}{2gL}\right)$$

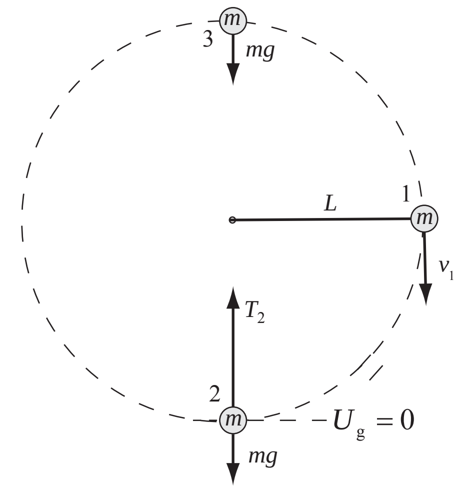
Substitute numerical values and evaluate $\theta_{\max}$:

$$\theta_{\max} = \cos^{-1}\left[1 - \frac{(4.5\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)(3.0\,\text{m})}\right] = \boxed{49°}$$

55 •• **[SSM]** A pendulum consists of a string of length L and a bob of mass m. The bob is rotated until the string is horizontal. The bob is then projected downward with the minimum initial speed needed to enable the bob to make a full revolution in the vertical plane. (*a*) What is the maximum kinetic energy of the bob? (*b*) What is the tension in the string when the kinetic energy is maximum?

Picture the Problem Let the system consist of Earth and the pendulum bob. Then $W_{\text{ext}} = 0$. Choose $U_g = 0$ at the bottom of the circle and let points 1, 2 and 3 represent the bob's initial point, lowest point and highest point, respectively. The bob will gain speed and kinetic energy until it reaches point 2 and slow down

until it reaches point 3; so it has its maximum kinetic energy when it is at point 2. We can use Newton's second law at points 2 and 3 in conjunction with conservation of mechanical energy to find the maximum kinetic energy of the bob and the tension in the string when the bob has its maximum kinetic energy.



(*a*) Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the bob at the top of the circle and solve for v_3^2:

$$mg = m\frac{v_3^2}{L} \Rightarrow v_3^2 = gL$$

Apply conservation of mechanical energy to the system to express the relationship between K_2, K_3 and U_3:

$$K_3 - K_2 + U_3 - U_2 = 0$$

or, because $U_2 = 0$,

$$K_3 - K_2 + U_3 = 0$$

Solving for K_2 yields:

$$K_2 = K_{\max} = K_3 + U_3$$

Substituting for K_3 and U_3 yields:

$$K_{\max} = \tfrac{1}{2}mv_3^2 + mg(2L)$$

Substitute for v_3^2 and simplify to obtain:

$$K_{\max} = \tfrac{1}{2}m(gL) + 2mgL = \boxed{\tfrac{5}{2}mgL}$$

(*b*) Apply $\sum F_{\text{radial}} = ma_{\text{c}}$ to the bob at the bottom of the circle and solve for T_2:

$$F_{\text{net}} = T_2 - mg = m\frac{v_2^2}{L}$$

and

$$T_2 = mg + m\frac{v_2^2}{L} \qquad (1)$$

Use conservation of mechanical energy to relate the energies of the bob at points 2 and 3 and solve for K_2:

$K_3 - K_2 + U_3 - U_2 = 0$ where $U_2 = 0$ and

$K_2 = K_3 + U_3 = \frac{1}{2}mv_3^2 + mg(2L)$

Substitute for v_3^2 and K_2 to obtain:

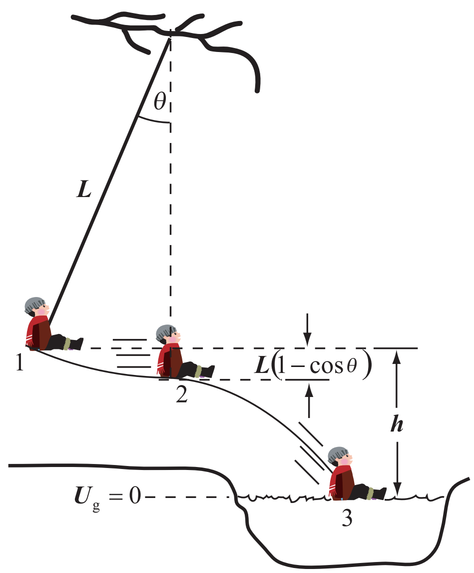
$\frac{1}{2}mv_2^2 = \frac{1}{2}m(gL) + mg(2L) \Rightarrow v_2^2 = 5gL$

Substitute for v_2^2 in equation (1) and simplify to obtain:

$$T_2 = mg + m\frac{5gL}{L} = \boxed{6mg}$$

56 •• A child whose weight is 360 N swings out over a pool of water using a rope attached to the branch of a tree at the edge of the pool. The branch is 12 m above ground level and the surface of the water is 1.8 m below ground level. The child holds onto the rope at a point 10.6 m from the branch and moves back until the angle between the rope and the vertical is 23°. When the rope is in the vertical position, the child lets go and drops into the pool. Find the speed of the child just as he impacts the surface of the water. (Model the child as a point particle attached to the rope 10.6 m from the branch.)

Picture the Problem Let the system consist of Earth and the child. Then $W_{ext} = 0$. In the figure, the child's initial position is designated with the numeral 1; the point at which the child releases the rope and begins to fall with a 2, and its point of impact with the water is identified with a 3. Choose $U_g = 0$ at the water level. While one could apply conservation of mechanical energy between points 1 and 2 and then between points 2 and 3, it is more direct to consider the energy transformations between points 1 and 3.



Apply conservation of mechanical energy between points 1 and 3:

$W_{ext} = \Delta K + \Delta U = 0$

$K_3 - K_1 + U_3 - U_1 = 0$

where U_3 and K_1 are zero.

Substitute for K_3 and U_1;

$\frac{1}{2}mv_3^2 - mg[h + L(1 - \cos\theta)] = 0$

Solving for v_3 yields:

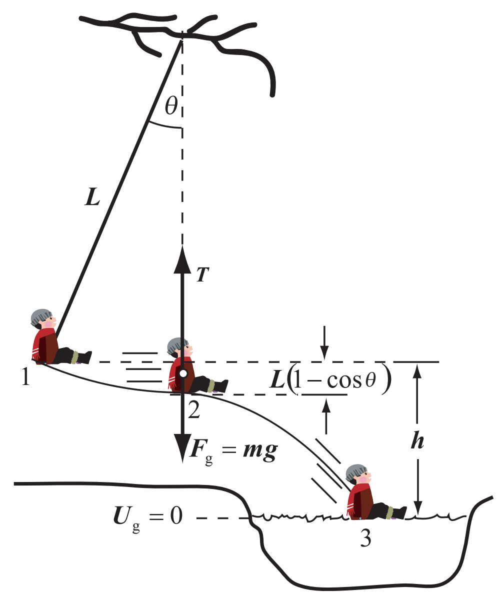
$$v_3 = \sqrt{2g[h + L(1 - \cos\theta)]}$$

Substitute numerical values and evaluate v_3:

$$v_3 = \sqrt{2\left(9.81\,\text{m/s}^2\right)\left[3.2\,\text{m} + (10.6\,\text{m})(1-\cos 23°)\right]} = \boxed{8.9\,\text{m/s}}$$

57 •• Walking by a pond, you find a rope attached to a stout tree limb that is 5.2 m above ground level. You decide to use the rope to swing out over the pond. The rope is a bit frayed, but supports your weight. You estimate that the rope might break if the tension is 80 N greater than your weight. You grab the rope at a point 4.6 m from the limb and move back to swing out over the pond. (Model yourself as a point particle attached to the rope 4.6 m from the limb.) (*a*) What is the maximum safe initial angle between the rope and the vertical at which it will not break during the swing? (*b*) If you begin at this maximum angle, and the surface of the pond is 1.2 m below the level of the ground, with what speed will you enter the water if you let go of the rope when the rope is vertical?

Picture the Problem Let the system consist of you and Earth. Then there are no external forces to do work on the system and $W_{\text{ext}} = 0$. In the figure, your initial position is designated with the numeral 1, the point at which you release the rope and begin to fall with a 2, and your point of impact with the water is identified with a 3. Choose $U_g = 0$ at the water level. We can apply Newton's second law to the forces acting on you at point 2 and apply conservation of mechanical energy between points 1 and 2 to determine the maximum angle at which you can begin your swing and then between points 1 and 3 to determine the speed with which you will hit the water.



(*a*) Use conservation of mechanical energy to relate your speed at point 2 to your potential energy there and at point 1:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

or

$$K_2 - K_1 + U_2 - U_1 = 0$$

Because $K_1 = 0$:

$$\tfrac{1}{2}mv_2^2 + mgh - \left[mgL(1-\cos\theta) + mgh\right] = 0$$

Solve this equation for θ to obtain:

$$\theta = \cos^{-1}\left[1 - \frac{v_2^2}{2gL}\right] \qquad (1)$$

Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to yourself at point 2 and solve for T:

$$T - mg = m\frac{v_2^2}{L} \text{ and } T = mg + m\frac{v_2^2}{L}$$

Because you've estimated that the rope might break if the tension in it exceeds your weight by 80 N, it must be that:

$$m\frac{v_2^2}{L} = 80\,\text{N} \Rightarrow v_2^2 = \frac{(80\,\text{N})L}{m}$$

Let's assume that your mass is 70 kg. Then:

$$v_2^2 = \frac{(80\,\text{N})(4.6\,\text{m})}{70\,\text{kg}} = 5.26\,\text{m}^2/\text{s}^2$$

Substitute numerical values in equation (1) to obtain:

$$\theta = \cos^{-1}\left[1 - \frac{5.26\,\text{m}^2/\text{s}^2}{2(9.81\,\text{m/s}^2)(4.6\,\text{m})}\right]$$
$$= 19.65° = \boxed{20°}$$

(*b*) Apply conservation of mechanical energy between points 1 and 3:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

or, because $U_3 = K_1 = 0$,

$$K_3 - U_1 = 0$$

Substitute for K_3 and U_1 to obtain:

$$\tfrac{1}{2}mv_3^2 - mg[h + L(1 - \cos\theta)] = 0$$

Solving for v_3 yields:

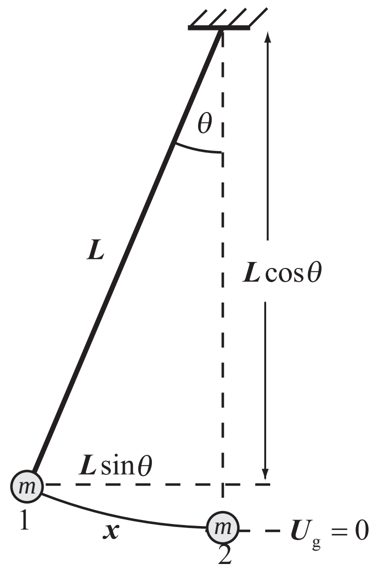
$$v_3 = \sqrt{2g[h + L(1 - \cos\theta)]}$$

Substitute numerical values and evaluate v_3:

$$v_3 = \sqrt{2(9.81\,\text{m/s}^2)[1.2\,\text{m} + (4.6\,\text{m})(1 - \cos 19.65°)]} = \boxed{5.4\,\text{m/s}}$$

58 ••• A pendulum bob of mass m is attached to a light string of length L and is also attached to a spring of force constant k. With the pendulum in the position shown in Figure 7-47, the spring is at its unstressed length. If the bob is now pulled aside so that the string makes a *small* angle θ with the vertical and released, what is the speed of the bob as it passes through the equilibrium position? *Hint: Recall the small-angle approximations: if* θ *is expressed in radians, and if* $|\theta| < 1$, *then* $\sin\theta \approx \tan\theta \approx \theta$ *and* $\cos\theta \approx 1 - \frac{1}{2}\theta^2$.

Picture the Problem Choose $U_g = 0$ at point 2, the lowest point of the bob's trajectory and let the system consist of the bob, spring, string and Earth. Given this choice, there are no external forces doing work on the system. Because $\theta \ll 1$, we can use the trigonometric series for the sine and cosine functions to approximate these functions. The bob's initial energy is partially gravitational potential and partially potential energy stored in the stretched spring. As the bob swings down to point 2 this energy is transformed into kinetic energy. By equating these energies, we can derive an expression for the speed of the bob at point 2.



Apply conservation of mechanical energy to the system as the pendulum bob swings from point 1 to point 2:

$$W_{ext} = \Delta K + \Delta U = 0$$

or, because $K_1 = U_2 = 0$,

$$K_2 - U_1 = 0$$

Substituting for K_2 and U_1 yields:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}kx^2 - mgL(1-\cos\theta) = 0$$

Note, from the figure, that when $\theta \ll 1$, $x \approx L\sin\theta$:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}k(L\sin\theta)^2 - mgL(1-\cos\theta) = 0$$

Also, when $\theta \ll 1$:

$$\sin\theta \approx \theta \text{ and } \cos\theta \approx 1 - \tfrac{1}{2}\theta^2$$

Substitute for $\sin\theta$ and $\cos\theta$ to obtain:

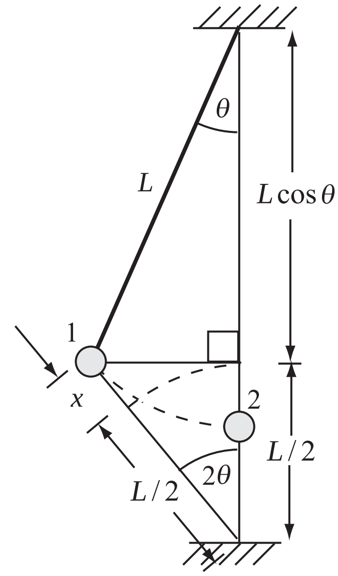
$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}k(L\theta)^2 - mgL\left[1 - \left(1 - \tfrac{1}{2}\theta^2\right)\right]$$

Solving for v_2 yields:

$$v_2 = \boxed{L\theta\sqrt{\frac{k}{m} + \frac{g}{L}}}$$

59 ••• [SSM] A pendulum is suspended from the ceiling and attached to a spring fixed to the floor directly below the pendulum support (Figure 7-48). The mass of the pendulum bob is m, the length of the pendulum is L, and the force constant is k. The unstressed length of the spring is $L/2$ and the distance between the floor and ceiling is $1.5L$. The pendulum is pulled aside so that it makes an

angle θ with the vertical and is then released from rest. Obtain an expression for the speed of the pendulum bob as the bob passes through a point directly below the pendulum support.



Picture the Problem Choose $U_g = 0$ at point 2, the lowest point of the bob's trajectory and let the system consist of Earth, the ceiling, the spring, and the pendulum bob. Given this choice, there are no external forces doing work to change the energy of the system. The bob's initial energy is partially gravitational potential and partially potential energy stored in the stretched spring. As the bob swings down to point 2 this energy is transformed into kinetic energy. By equating these energies, we can derive an expression for the speed of the bob at point 2.

Apply conservation of mechanical energy to the system as the pendulum bob swings from point 1 to point 2:

$$W_{ext} = \Delta K + \Delta U_g + \Delta U_s = 0$$

or, because $K_1 = U_{g,2} = U_{s,2} = 0$,

$$K_2 - U_{g,1} - U_{s,1} = 0$$

Substituting for K_2, $U_{g,1}$, and $U_{s,2}$ yields:

$$\tfrac{1}{2}mv_2^2 - mgL(1-\cos\theta) - \tfrac{1}{2}kx^2 = 0 \quad (1)$$

Apply the Pythagorean theorem to the lower triangle in the diagram to obtain:

$$\begin{aligned}\left(x+\tfrac{1}{2}L\right)^2 &= L^2\left[\sin^2\theta + \left(\tfrac{3}{2}-\cos\theta\right)^2\right] = L^2\left[\sin^2\theta + \tfrac{9}{4} - 3\cos\theta + \cos^2\theta\right]\\ &= L^2\left(\tfrac{13}{4} - 3\cos\theta\right)\end{aligned}$$

Take the square root of both sides of the equation to obtain:

$$x + \tfrac{1}{2}L = L\sqrt{\left(\tfrac{13}{4} - 3\cos\theta\right)}$$

Solving for x yields:

$$x = L\left[\sqrt{\left(\tfrac{13}{4} - 3\cos\theta\right)} - \tfrac{1}{2}\right]$$

Substitute for x in equation (1) to obtain:

$$\tfrac{1}{2}mv_2^2 = \tfrac{1}{2}kL^2\left[\sqrt{\left(\tfrac{13}{4} - 3\cos\theta\right)} - \tfrac{1}{2}\right]^2 + mgL(1-\cos\theta)$$

Solving for v_2 yields:

$$v_2 = \boxed{L\sqrt{2\frac{g}{L}(1-\cos\theta)+\frac{k}{m}\left(\sqrt{\tfrac{13}{4}-3\cos\theta}-\tfrac{1}{2}\right)^2}}$$

Total Energy and Non-conservative Forces

60 • In a volcanic eruption, 4.00 km^3 of mountain with an average density of 1600 kg/m^3 was raised an average height of 500 m. (*a*) What is the minimum amount of energy, in joules, that was released during this eruption? (*b*) The energy released by thermonuclear bombs is measured in megatons of TNT, where 1 megaton of TNT = 4.2×10^{15} J. Convert your answer for Part (*a*) to megatons of TNT.

Picture the Problem The energy of the eruption is initially in the form of the kinetic energy of the material it thrusts into the air. This energy is then transformed into gravitational potential energy as the material rises.

(*a*) Express the energy of the eruption in terms of the height Δh to which the debris rises:

$$E = mg\Delta h$$

Relate the mass of the material to its density and volume:

$$m = \rho V$$

Substitute for *m* to obtain:

$$E = \rho V g\Delta h$$

Substitute numerical values and evaluate *E*:

$$E = \left(1600\,\text{kg/m}^3\right)\left(4.00\,\text{km}^3\right)\left(9.81\,\text{m/s}^2\right)\left(500\,\text{m}\right) = \boxed{3.14\times10^{16}\ \text{J}}$$

(*b*) Convert 3.14×10^{16} J to megatons of TNT:

$$3.14\times10^{16}\ \text{J} = 3.14\times10^{16}\ \text{J}\times\frac{1\,\text{Mton TNT}}{4.2\times10^{15}\ \text{J}} = \boxed{7.5\,\text{Mton TNT}}$$

61 • To work off a large pepperoni pizza you ate on Friday night, on Saturday morning you climb a 120-m-high hill. (*a*) Assuming a reasonable value for your mass, determine your increase in gravitational potential energy. (*b*) Where does this energy come from? (*c*) The human body is typically 20 percent efficient. How much energy was converted into thermal energy? (*d*) How much chemical energy is expended by you during the climb? Given that oxidation

(burning) of a single slice of pepperoni pizza releases about 1.0 MJ (250 food calories) of energy, do you think one climb up the hill is enough?

Picture the Problem The work you did equals the change in your gravitational potential energy and is enabled by the transformation of metabolic energy in your muscles. Let the system consist of you and Earth and apply the conservation of mechanical energy to this system.

(*a*) Your increase in gravitational potential energy is:

$$\Delta U_{\text{g}} = mg\Delta h$$

Assuming that your mass is 70 kg, your increase in gravitational potential energy is:

$$\Delta U_{\text{g}} = (70\,\text{kg})(9.81\,\text{m/s}^2)(120\,\text{m}) = 82.4\,\text{kJ} = \boxed{82\,\text{kJ}}$$

(*b*) The energy required to do this work comes from the conversion of stored internal chemical energy into gravitational potential energy and thermal energy.

(*c*) Because only 20% of the energy you expend is converted into gravitational potential energy, four times this amount is converted into wasted thermal energy:

$$\Delta E_{\text{therm}} = 4\Delta U_{\text{g}}$$

Substitute the numerical value of ΔU_{g} and evaluate ΔE_{therm}:

$$\Delta E_{\text{therm}} = 4(82.4\,\text{kJ}) = \boxed{328\,\text{kJ}}$$

(*d*) Apply the conservation of mechanical energy to the system to obtain:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} + \Delta E_{\text{chem}} = 0$$

or, because you begin and end your ascent at rest, $\Delta K = 0$ and,

$$\Delta U_{\text{g}} + \Delta E_{\text{therm}} + \Delta E_{\text{chem}} = 0$$

Solving for ΔE_{chem} yields:

$$\Delta E_{\text{chem}} = -\Delta U_{\text{g}} - \Delta E_{\text{therm}}$$

Substitute numerical values and evaluate ΔE_{chem}:

$$\Delta E_{\text{chem}} = -(82.4\,\text{kJ}) - (328\,\text{kJ}) = -410\,\text{kJ} = \boxed{-0.410\,\text{MJ}}$$

The climb uses up about 40% of the energy released from the pizza.

62 • A 2000-kg car moving at an initial speed of 25 m/s along a horizontal road skids to a stop in 60 m. (*a*) Find the energy dissipated by friction. (*b*) Find the coefficient of kinetic friction between the tires and the road. (*Note*: When

stopping without skidding and using conventional brakes, 100 percent of the kinetic energy is dissipated by friction within the brakes. With regenerative braking, such as that used in hybrid vehicles, only 70 percent of the kinetic energy is dissipated.)

Picture the Problem Let the car and Earth constitute the system. As the car skids to a stop on a horizontal road, its kinetic energy is transformed into internal (thermal) energy. Knowing that energy is transformed into heat by friction, we can use the definition of the coefficient of kinetic friction to calculate its value.

(*a*) The energy dissipated by friction is given by:

$$f\Delta s = \Delta E_{\text{therm}}$$

Apply the work-energy theorem for problems with kinetic friction:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} = \Delta E_{\text{mech}} + f\Delta s$$

or, because $\Delta E_{\text{mech}} = \Delta K = -K_{\text{i}}$ and $W_{\text{ext}} = 0$,

$$0 = -\tfrac{1}{2}mv_{\text{i}}^2 + f\Delta s \Rightarrow f\Delta s = \tfrac{1}{2}mv_{\text{i}}^2$$

Substitute numerical values and evaluate $f\Delta s$:

$$f\Delta s = \tfrac{1}{2}(2000\,\text{kg})(25\,\text{m/s})^2 = 6.25\times10^5\ \text{J} = \boxed{6.3\times10^5\ \text{J}}$$

(*b*) Relate the kinetic friction force to the coefficient of kinetic friction and the weight of the car:

$$f_{\text{k}} = \mu_{\text{k}}mg \Rightarrow \mu_{\text{k}} = \frac{f_{\text{k}}}{mg} \qquad (1)$$

Express the relationship between the energy dissipated by friction and the kinetic friction force:

$$\Delta E_{\text{therm}} = f_{\text{k}}\Delta s \Rightarrow f_{\text{k}} = \frac{\Delta E_{\text{therm}}}{\Delta s}$$

Substitute for f_{k} in equation (1) to obtain:

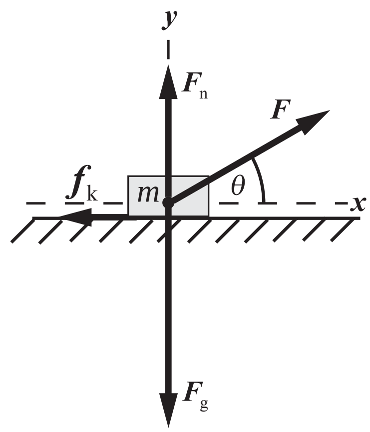
$$\mu_{\text{k}} = \frac{\Delta E_{\text{therm}}}{mg\Delta s}$$

Substitute numerical values and evaluate μ_{k}:

$$\mu_{\text{k}} = \frac{6.25\times10^5\ \text{J}}{(2000\,\text{kg})(9.81\,\text{m/s}^2)(60\,\text{m})} = \boxed{0.53}$$

63 • An 8.0-kg sled is initially at rest on a horizontal road. The coefficient of kinetic friction between the sled and the road is 0.40. The sled is pulled a distance of 3.0 m by a force of 40 N applied to the sled at an angle of 30° above the horizontal. (*a*) Find the work done by the applied force. (*b*) Find the energy dissipated by friction. (*c*) Find the change in the kinetic energy of the sled. (*d*) Find the speed of the sled after it has traveled 3.0 m.

Picture the Problem Let the system consist of the sled and Earth. Then the 40-N force is external to the system. The free-body diagram shows the forces acting on the sled as it is pulled along a horizontal road. The work done by the applied force can be found using the definition of work. To find the energy dissipated by friction, we'll use Newton's second law to determine f_k and then use it in the definition of work. The change in the kinetic energy of the sled is equal to the net work done on it. Finally, knowing the kinetic energy of the sled after it has traveled 3.0 m will allow us to solve for its speed at that location.



(*a*) The work done by the applied force is given by:

$$W_{ext} = \vec{F}\cdot\vec{s} = Fs\cos\theta$$

Substitute numerical values and evaluate W_{ext}:

$$W_{ext} = (40\,\text{N})(3.0\,\text{m})\cos 30° = 103.9\,\text{J} = \boxed{0.10\,\text{kJ}}$$

(*b*) The energy dissipated by friction as the sled is dragged along the surface is given by:

$$\Delta E_{therm} = f\Delta x = \mu_k F_n \Delta x \qquad (1)$$

Apply $\sum F_y = ma_y$ to the sled:

$$F_n + F\sin\theta - mg = 0$$

Solving for F_n yields:

$$F_n = mg - F\sin\theta$$

Substitute for F_n in equation (1) to obtain:

$$\Delta E_{therm} = \mu_k \Delta x(mg - F\sin\theta)$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{therm} = (0.40)(3.0\,\text{m})\left[(8.0\,\text{kg})(9.81\,\text{m/s}^2) - (40\,\text{N})\sin 30°\right] = 70.2\,\text{J} = \boxed{70\,\text{J}}$$

(*c*) Apply the work-energy theorem for systems with kinetic friction:

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm} = \Delta E_{mech} + f\Delta s$$

or, because $\Delta E_{mech} = \Delta K + \Delta U$ and $\Delta U = 0$,

$$W_{ext} = \Delta K + \Delta E_{therm}$$

Solving for ΔK yields:

$$\Delta K = W_{ext} - \Delta E_{therm}$$

Substitute numerical values and evaluate ΔK:

$$\Delta K = 103.9\,\text{J} - 70.2\,\text{J} = 33.7\,\text{J} = \boxed{34\,\text{J}}$$

(*d*) Because $K_i = 0$:

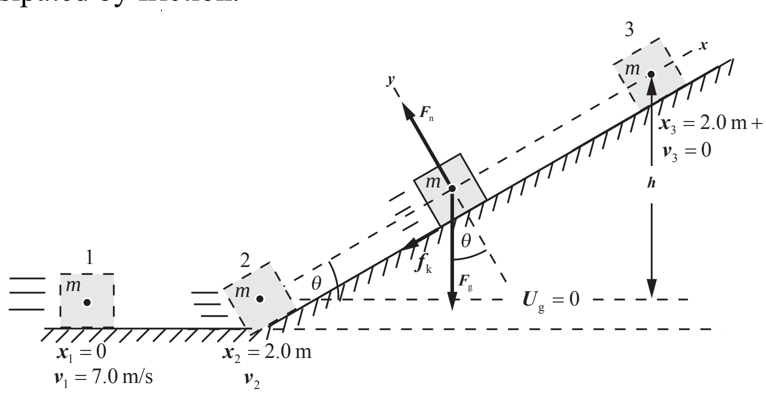
$$K_f = \Delta K = \tfrac{1}{2}mv_f^2 \Rightarrow v_f = \sqrt{\frac{2\Delta K}{m}}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{\frac{2(33.7\,\text{J})}{8.0\,\text{kg}}} = \boxed{2.9\,\text{m/s}}$$

64 •• Using Figure 7-41, suppose that the surfaces described are not frictionless and that the coefficient of kinetic friction between the block and the surfaces is 0.30. The block has an initial speed of 7.0 m/s and slides 2.0 m before reaching the ramp. Find (*a*) the speed of the block when it reaches the ramp, and (*b*) the distance that the block slides along the inclined surface before coming momentarily to rest. (Neglect any energy dissipated along the transition curve.)

Picture the Problem The pictorial representation shows the block in its initial, intermediate, and final states. It also shows a choice for $U_g = 0$. Let the system consist of the block, ramp, and Earth. Then the kinetic energy of the block at the foot of the ramp is equal to its initial kinetic energy less the energy dissipated by friction. The block's kinetic energy at the foot of the incline is partially converted to gravitational potential energy and partially converted to thermal energy (dissipated by friction) as the block slides up the incline. The free-body diagram shows the forces acting on the block as it slides up the incline. Applying Newton's second law to the block will allow us to determine f_k and express the energy dissipated by friction.



(a) Apply conservation of energy to the system while the block is moving horizontally:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} = \Delta K + \Delta U + f\Delta s$$

or, because $\Delta U = W_{\text{ext}} = 0$,

$$0 = \Delta K + f\Delta s = K_2 - K_1 + f\Delta s$$

Solving for K_2 yields:

$$K_2 = K_1 - f\Delta s$$

Substitute for K_2, K_1, and $f\Delta s$ to obtain:

$$\tfrac{1}{2}mv_2^2 = \tfrac{1}{2}mv_1^2 - \mu_k mg\Delta x$$

Solving for v_2 yields:

$$v_2 = \sqrt{v_1^2 - 2\mu_k g\Delta x}$$

Substitute numerical values and evaluate v_2:

$$v_2 = \sqrt{(7.0\,\text{m/s})^2 - 2(0.30)(9.81\,\text{m/s}^2)(2.0\,\text{m})} = 6.10\,\text{m/s} = \boxed{6.1\,\text{m/s}}$$

(b) Apply conservation of energy to the system while the block is on the incline:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} = \Delta K + \Delta U + f\Delta s$$

or, because $K_3 = U_2 = W_{\text{ext}} = 0$,

$$0 = -K_2 + U_3 + f\Delta s \qquad (1)$$

Apply $\sum F_y = ma_y$ to the block when it is on the incline:

$$F_n - mg\cos\theta = 0 \Rightarrow F_n = mg\cos\theta$$

Express $f\Delta s$:

$$f\Delta s = f_k\ell = \mu_k F_n\ell = \mu_k mg\ell\cos\theta$$

The final potential energy of the block is:

$$U_3 = mg\ell\sin\theta$$

Substitute for U_3, K_2, and $f\Delta s$ in equation (1) to obtain:

$$0 = -\tfrac{1}{2}mv_2^2 + mg\ell\sin\theta + \mu_k mg\ell\cos\theta$$

Solving for ℓ yields:

$$\ell = \frac{\tfrac{1}{2}v_2^2}{g(\sin\theta + \mu_k\cos\theta)}$$

Substitute numerical values and evaluate ℓ:

$$\ell = \frac{\tfrac{1}{2}(6.10\,\text{m/s})^2}{(9.81\,\text{m/s}^2)(\sin 40° + (0.30)\cos 40°)} = \boxed{2.2\,\text{m}}$$

65 •• [SSM] The 2.0-kg block in Figure 7-49 slides down a frictionless curved ramp, starting from rest at a height of 3.0 m. The block then slides 9.0 m on a rough horizontal surface before coming to rest. (*a*) What is the speed of the block at the bottom of the ramp? (*b*) What is the energy dissipated by friction? (*c*) What is the coefficient of kinetic friction between the block and the horizontal surface?

Picture the Problem Let the system include the block, the ramp and horizontal surface, and Earth. Given this choice, there are no external forces acting that will change the energy of the system. Because the curved ramp is frictionless, mechanical energy is conserved as the block slides down it. We can calculate its speed at the bottom of the ramp by using conservation of energy. The potential energy of the block at the top of the ramp or, equivalently, its kinetic energy at the bottom of the ramp is converted into thermal energy during its slide along the horizontal surface.

(*a*) Let the numeral 1 designate the initial position of the block and the numeral 2 its position at the foot of the ramp. Choose $U_g = 0$ at point 2 and use conservation of energy to relate the block's potential energy at the top of the ramp to its kinetic energy at the bottom:

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm}$$

or, because $W_{ext} = K_i = U_f = \Delta E_{therm} = 0$,

$$0 = \tfrac{1}{2}mv_2^2 - mg\Delta h = 0 \Rightarrow v_2 = \sqrt{2g\Delta h}$$

Substitute numerical values and evaluate v_2:

$$v_2 = \sqrt{2(9.81\,\text{m/s}^2)(3.0\,\text{m})} = 7.67\,\text{m/s}$$
$$= \boxed{7.7\,\text{m/s}}$$

(b) The energy dissipated by friction is responsible for changing the thermal energy of the system:

$$W_f + \Delta K + \Delta U = \Delta E_{therm} + \Delta K + \Delta U$$
$$= 0$$

Because $\Delta K = 0$ for the entire slide; beginning at the top and ending when the block is at rest again:

$$W_f = -\Delta U = -(U_2 - U_1) = U_1$$

Substituting for U_1 yields:

$$W_f = mg\Delta h$$

Substitute numerical values and evaluate U_1:

$$W_f = (2.0\,\text{kg})(9.81\,\text{m/s}^2)(3.0\,\text{m}) = 58.9\,\text{J}$$
$$= \boxed{59\,\text{J}}$$

(c) The energy dissipated by friction is given by:

$$\Delta E_{\text{therm}} = f\Delta s = \mu_k mg\Delta x$$

Solving for μ_k yields:

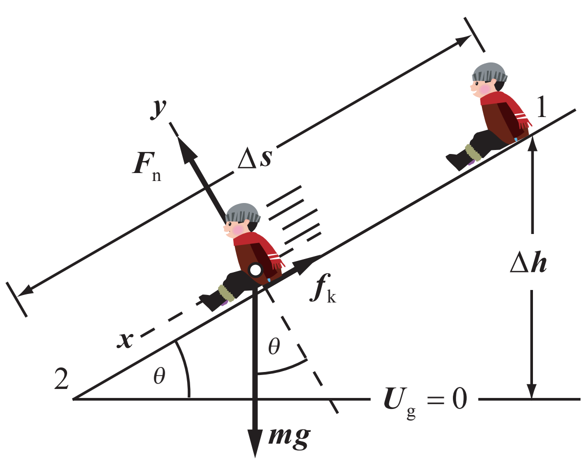
$$\mu_k = \frac{\Delta E_{\text{therm}}}{mg\Delta x}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{58.9\,\text{J}}{(2.0\,\text{kg})(9.81\,\text{m/s}^2)(9.0\,\text{m})}$$
$$= \boxed{0.33}$$

66 •• A 20-kg girl slides down a playground slide with a vertical drop of 3.2 m. When she reaches the bottom of the slide, her speed is 1.3 m/s. (*a*) How much energy was dissipated by friction? (*b*) If the slide is inclined at 20° with the horizontal, what is the coefficient of kinetic friction between the girl and the slide?

Picture the Problem Let the system consist of Earth, the girl, and the slide. Given this choice, there are no external forces doing work to change the energy of the system**.** By the time she reaches the bottom of the slide, her potential energy at the top of the slide has been converted into kinetic and thermal energy. Choose $U_g = 0$ at the bottom of the slide and denote the top and bottom of the slide as shown in the figure. We'll use the work-energy theorem with friction to relate these quantities and the forces acting on her during her slide to determine the friction force that transforms some of her initial potential energy into thermal energy.



(*a*) Express the work-energy theorem:

$$W_{ext} = \Delta K + \Delta U + \Delta E_{therm} = 0$$

Because $U_2 = K_1 = W_{ext} = 0$:

$$0 = K_2 - U_1 + \Delta E_{therm} = 0$$

or

$$\Delta E_{therm} = U_1 - K_2 = mg\Delta h - \tfrac{1}{2}mv_2^2$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{therm} = (20\,\text{kg})(9.81\,\text{m/s}^2)(3.2\,\text{m}) - \tfrac{1}{2}(20\,\text{kg})(1.3\,\text{m/s})^2 = 611\,\text{J} = \boxed{0.61\,\text{kJ}}$$

(*b*) Relate the energy dissipated by friction to the kinetic friction force and the distance over which this force acts:

$$\Delta E_{therm} = f\Delta s = \mu_k F_n \Delta s$$

Solve for μ_k to obtain:

$$\mu_k = \frac{\Delta E_{therm}}{F_n \Delta s} \qquad (1)$$

Apply $\sum F_y = ma_y$ to the girl and solve for F_n:

$$F_n - mg\cos\theta = 0 \Rightarrow F_n = mg\cos\theta$$

Referring to the figure, relate Δh to Δs and θ:

$$\Delta s = \frac{\Delta h}{\sin\theta}$$

Substitute for Δs and F_n in equation (1) and simplify to obtain:

$$\mu_k = \frac{\Delta E_{therm}}{mg\dfrac{\Delta h}{\sin\theta}\cos\theta} = \frac{\Delta E_{therm}\tan\theta}{mg\Delta h}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{(611\,\text{J})\tan 20°}{(20\,\text{kg})(9.81\,\text{m/s}^2)(3.2\,\text{m})} = \boxed{0.35}$$

67 •• In Figure 7-50, the coefficient of kinetic friction between the 4.0-kg block and the shelf is 0.35. (*a*) Find the energy dissipated by friction when the 2.0-kg block falls a distance *y*. (*b*) Find the change in mechanical energy E_{mech} of the two-block–Earth system during the time it takes the 2.0-kg block to fall a distance *y*. (*c*) Use your result for Part (*b*) to find the speed of either block after the 2.0-kg block falls 2.0 m.

Picture the Problem Let the system consist of the two blocks, the shelf, and Earth. Given this choice, there are no external forces doing work to change the energy of the system. Due to the friction between the 4.0-kg block and the surface on which it slides, not all of the energy transformed during the fall of the 2.0-kg block is realized in the form of kinetic energy. We can find the energy dissipated by friction and then use the work-energy theorem with kinetic friction to find the speed of either block when they have moved the given distance.

(*a*) The energy dissipated by friction when the 2.0-kg block falls a distance *y* is given by:

$$\Delta E_{\text{therm}} = f\Delta s = \mu_k m_1 g y$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{\text{therm}} = (0.35)(4.0\,\text{kg})(9.81\,\text{m/s}^2)y = (13.7\,\text{N})y = \boxed{(14\,\text{N})y}$$

(*b*) From the work-energy theorem with kinetic friction we have:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}}$$

or, because $W_{\text{ext}} = 0$ and $E_{\text{mech,i}} = 0$,

$$E_{\text{mech}} = -\Delta E_{\text{therm}} = \boxed{-(14\,\text{N})y}$$

(*c*) The total energy of the system is given by:

$$\tfrac{1}{2}(m_1 + m_2)v^2 - m_2 g y + \Delta E_{\text{therm}} = 0$$

Solving for *v* yields:

$$v = \sqrt{\frac{2(m_2 g y - \Delta E_{\text{therm}})}{m_1 + m_2}}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{2[(2.0\,\text{kg})(9.81\,\text{m/s}^2)(2.0\,\text{m}) - (13.7\,\text{N})(2.0\,\text{m})]}{4.0\,\text{kg} + 2.0\,\text{kg}}} = \boxed{2.0\,\text{m/s}}$$

68 •• A small object of mass *m* moves in a horizontal circle of radius *r* on a rough table. It is attached to a horizontal string fixed at the center of the circle. The speed of the object is initially v_0. After completing one full trip around the circle, the speed of the object is $0.5v_0$. (*a*) Find the energy dissipated by friction during that one revolution in terms of *m*, v_0, and *r*. (*b*) What is the coefficient of kinetic friction? (*c*) How many more revolutions will the object make before coming to rest?

Picture the Problem Let the system consist of the particle, the table, and Earth. Then $W_{\text{ext}} = 0$ and the energy dissipated by friction during one revolution is the change in the thermal energy of the system.

(*a*) Apply the work-energy theorem with kinetic friction to obtain:

$$W_{ext} = \Delta K + \Delta U + \Delta E_{therm}$$

or, because $\Delta U = W_{ext} = 0$,

$$0 = \Delta K + \Delta E_{therm}$$

Substitute for ΔK_f and simplify to obtain:

$$\begin{aligned}\Delta E_{therm} &= -\left(\tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_i^2\right)\\ &= -\left[\tfrac{1}{2}m\left(\tfrac{1}{2}v_0\right)^2 - \tfrac{1}{2}m\left(v_0\right)^2\right]\\ &= \boxed{\tfrac{3}{8}mv_0^2}\end{aligned}$$

(*b*) Relate the energy dissipated by friction to the distance traveled and the coefficient of kinetic friction:

$$\Delta E_{therm} = f\Delta s = \mu_k mg\Delta s = \mu_k mg(2\pi r)$$

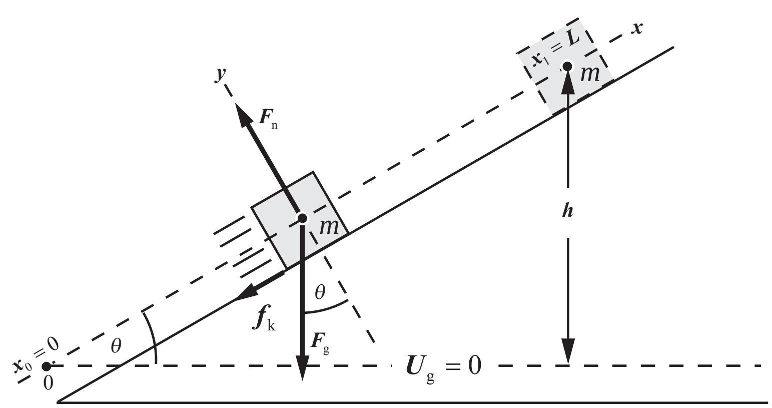
Substitute for ΔE and solve for μ_k to obtain:

$$\mu_k = \frac{\Delta E_{therm}}{2\pi mgr} = \frac{\frac{3}{8}mv_0^2}{2\pi mgr} = \boxed{\frac{3v_0^2}{16\pi gr}}$$

(*c*) Because the object lost $\frac{3}{4}K_i$ in one revolution, it will only require another 1/3 revolution to lose the remaining $\frac{1}{4}K_i$

69 •• [SSM] The initial speed of a 2.4-kg box traveling up a plane inclined 37° to the horizontal is 3.8 m/s. The coefficient of kinetic friction between the box and the plane is 0.30. (*a*) How far along the incline does the box travel before coming to a stop? (*b*) What is its speed when it has traveled half the distance found in Part (*a*)?

Picture the Problem The box will slow down and stop due to the dissipation of thermal energy. Let the system be Earth, the box, and the inclined plane and apply the work-energy theorem with friction. With this choice of the system, there are no external forces doing work to change the energy of the system. The pictorial representation shows the forces acting on the box when it is moving up the incline.



(*a*) Apply the work-energy theorem with friction to the system:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} = \Delta K + \Delta U + \Delta E_{\text{therm}}$$

Substitute for ΔK, ΔU, and ΔE_{therm} to obtain:

$$0 = \tfrac{1}{2}mv_1^2 - \tfrac{1}{2}mv_0^2 + mgh + \mu_k F_n L \quad (1)$$

Referring to the free-body diagram, relate the normal force to the weight of the box and the angle of the incline:

$$F_n = mg\cos\theta$$

Relate h to the distance L along the incline:

$$h = L\sin\theta$$

Substitute in equation (1) to obtain:

$$\mu_k mgL\cos\theta + \tfrac{1}{2}mv_1^2 - \tfrac{1}{2}mv_0^2 + mgL\sin\theta = 0 \qquad (2)$$

Setting $v_1 = 0$ and solving equation (2) for L yields:

$$L = \frac{v_0^2}{2g(\mu_k\cos\theta + \sin\theta)}$$

Substitute numerical values and evaluate L:

$$L = \frac{(3.8\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)[(0.30)\cos 37° + \sin 37°]} = 0.8747\,\text{m} = \boxed{0.87\,\text{m}}$$

(*b*) Let $v_{\frac{1}{2}L}$ represent the box's speed when it is halfway up the incline. Then equation (2) becomes:

$$\mu_k mg\left(\tfrac{1}{2}L\right)\cos\theta + \tfrac{1}{2}mv_{\frac{1}{2}L}^2 - \tfrac{1}{2}mv_0^2 + mg\left(\tfrac{1}{2}L\right)\sin\theta = 0$$

Solving for $v_{\frac{1}{2}L}$ yields :

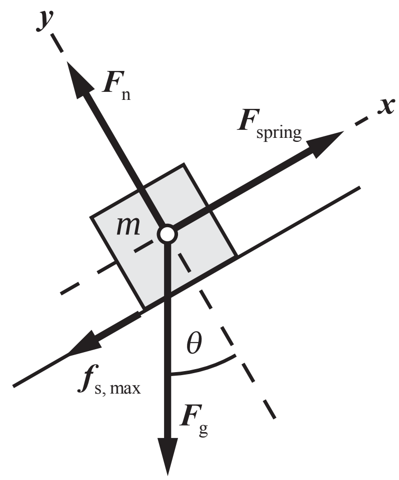
$$v_{\frac{1}{2}L} = \sqrt{v_0^2 - gL(\sin\theta + \mu_k\cos\theta)}$$

Substitute numerical values and evaluate $v_{\frac{1}{2}L}$:

$$v_f = \sqrt{(3.8\,\text{m/s})^2 - (9.81\,\text{m/s}^2)(0.8747\,\text{m})[\sin 37° + (0.30)\cos 37°]} = \boxed{2.7\,\text{m/s}}$$

70 ••• A block of mass m rests on a plane inclined an angle θ with the horizontal (Figure 7-51). A spring with force constant k is attached to the block. The coefficient of static friction between the block and plane is μ_s. The spring is pulled upward along the plane very slowly. (*a*) What is the extension of the spring the instant the block begins to move? (*b*) The block stops moving just as the extension of the contracting spring reaches zero. Express μ_k (the kinetic coefficient of friction) in terms of μ_s and θ.

Picture the Problem Let the system consist of Earth, the block, the incline, and the spring. With this choice of the system, there are no external forces doing work to change the energy of the system. The free-body diagram shows the forces acting on the block just before it begins to move. We can apply Newton's second law to the block to obtain an expression for the extension of the spring at this instant. We'll apply the work-energy theorem with friction to the second part of the problem.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the block when it is on the verge of sliding:

$$\sum F_x = F_{spring} - f_{s,max} - mg\sin\theta = 0$$

and

$$\sum F_y = F_n - mg\cos\theta = 0$$

Eliminate F_n, $f_{s,max}$, and F_{spring} between the two equations to obtain:

$$kd - \mu_s mg\cos\theta - mg\sin\theta = 0$$

Solving for d yields:

$$d = \boxed{\frac{mg}{k}\left(\sin\theta + \mu_s\cos\theta\right)}$$

(*b*) Begin with the work-energy theorem with friction and no work being done by an external force:

$$\begin{aligned} W_{ext} &= \Delta E_{mech} + \Delta E_{therm} \\ &= \Delta K + \Delta U_g + \Delta U_s + \Delta E_{therm} \end{aligned}$$

Because the block is at rest in both its initial and final states, $\Delta K = 0$ and:

$$\Delta U_g + \Delta U_s + \Delta E_{therm} = 0 \qquad (1)$$

Let $U_g = 0$ at the initial position of the block. Then:

$$\Delta U_g = U_{g,\text{final}} - U_{g,\text{initial}} = mgh - 0 = mgd\sin\theta$$

Express the change in the energy stored in the spring as it relaxes to its unstretched length:

$$\Delta U_s = U_{s,\text{final}} - U_{s,\text{initial}} = 0 - \tfrac{1}{2}kd^2 = -\tfrac{1}{2}kd^2$$

The energy dissipated by friction is:

$$\Delta E_{\text{therm}} = f\Delta s = f_k d = \mu_k F_n d = \mu_k mgd\cos\theta$$

Substitute in equation (1) to obtain:

$$mgd\sin\theta - \tfrac{1}{2}kd^2 + \mu_k mgd\cos\theta = 0$$

or

$$mg\sin\theta - \tfrac{1}{2}kd + \mu_k mg\cos\theta = 0$$

Substituting for d (from Part (a)) yields:

$$mg\sin\theta - \tfrac{1}{2}k\left[\frac{mg}{k}\left(\sin\theta + \mu_s\cos\theta\right)\right] + \mu_k mg\cos\theta = 0$$

Finally, solve for μ_k to obtain:

$$\mu_k = \boxed{\tfrac{1}{2}\left(\mu_s - \tan\theta\right)}$$

Mass and Energy

71 • (a) Calculate the rest energy of 1.0 g of dirt. (b) If you could convert this energy completely into electrical energy and sell it for \$0.10/kW·h, how much money would you take in? (c) If you could power a 100-W light bulb with this energy, for how long could you keep the bulb lit?

Picture the Problem The intrinsic rest energy in matter is related to the mass of matter through Einstein's equation $E_0 = mc^2$.

(a) The rest energy of the dirt is given by:

$$E_0 = mc^2$$

Substitute numerical values and evaluate E_0:

$$E_0 = \left(1.0\times10^{-3}\text{ kg}\right)\left(2.998\times10^{8}\text{ m/s}\right)^2 = 8.988\times10^{13}\text{ J} = \boxed{9.0\times10^{13}\text{ J}}$$

(*b*) Express kW·h in joules:

$$1\,\text{kW}\cdot\text{h} = \left(1\times10^{3}\ \text{J/s}\right)\left(1\,\text{h}\times\frac{3600\ \text{s}}{\text{h}}\right)$$
$$= 3.60\times10^{6}\ \text{J}$$

Convert 8.988 × 10^13 J to kW·h:

$$8.988\times10^{13}\ \text{J} = \left(8.988\times10^{13}\ \text{J}\right)\times\left(\frac{1\,\text{kW}\cdot\text{h}}{3.60\times10^{6}\ \text{J}}\right)$$
$$= 2.50\times10^{7}\ \text{kW}\cdot\text{h}$$

Determine the price of the electrical energy:

$$\text{Price} = \left(2.50\times10^{7}\ \text{kW}\cdot\text{h}\right)\left(\frac{\$0.10}{\text{kW}\cdot\text{h}}\right)$$
$$= \boxed{\$2.5\times10^{6}}$$

(*c*) Relate the energy consumed to its rate of consumption and the time:

$$\Delta E = P\Delta t \Rightarrow \Delta t = \frac{\Delta E}{P}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{8.988\times10^{13}\ \text{J}}{100\ \text{W}} = 8.988\times10^{11}\ \text{s}$$
$$= \boxed{9.0\times10^{11}\ \text{s}}$$
$$= 8.988\times10^{11}\ \text{s}\times\frac{1\ \text{y}}{3.156\times10^{7}\ \text{s}}$$
$$= \boxed{2.8\times10^{4}\ \text{y}}$$

72 • One kiloton of TNT, when detonated, yields an explosive energy of roughly 4 × 10^12 J. How much less is the total mass of the bomb remnants after the explosion than before? If you could find and reassemble the pieces, would this loss of mass be noticeable?

Picture the Problem We can use the equation expressing the equivalence of energy and matter, $E = \Delta mc^2$, to find the reduction in the mass of the bomb due to the explosion.

Solve $E = \Delta mc^2$ for Δm:

$$\Delta m = \frac{E}{c^2}$$

Substitute numerical values and evaluate Δm:

$$\Delta m = \frac{4\times10^{12}\ \text{J}}{\left(2.998\times10^{8}\ \text{m/s}\right)^2}$$
$$= 4.45\times10^{-5}\ \text{kg} \approx \boxed{4\times10^{-5}\ \text{kg}}$$

Express the ratio of Δm to the mass of the bomb before its explosion:

$$\frac{\Delta m}{m_{\text{bomb}}}=\frac{4.45\times10^{-5}\text{ kg}}{1\text{ kton}\times\frac{2000\text{ lb}}{\text{ton}}\times\frac{1\text{ kg}}{2.2046\text{ lb}}}\approx 5\times10^{-11}$$

No, not noticeable! The mass change, compared to the mass of the bomb, is negligible.

73 • Calculate your rest energy in both mega electron-volts and joules. If that energy could be converted completely to the kinetic energy of your car, estimate its speed. Use the nonrelativistic expression for kinetic energy and comment on whether or not your answer justifies using the nonrelativistic expression for kinetic energy.

Picture the Problem Your rest energy is given by $E_0 = mc^2$.

Your rest energy if given by:

$$E_0 = mc^2$$

Assuming that your mass is 70 kg, substitute numerical values and evaluate E_0:

$$E_0=(70\text{ kg})(2.998\times10^8\text{ m/s})^2 = 6.292\times10^{18}\text{ J} = \boxed{6.3\times10^{18}\text{ J}}$$

Convert E_0 to MeV to obtain:

$$E_0 = 6.292\times10^{18}\text{ J}\times\frac{1\text{ eV}}{1.602\times10^{-19}\text{ J}} = \boxed{3.9\times10^{31}\text{ MeV}}$$

The nonrelativistic expression for the kinetic energy of your car is:

$$K=\tfrac{1}{2}mv^2 \Rightarrow v=\sqrt{\frac{2K}{m}}$$

Assuming the mass of your car to be 1.4×10^3 kg (approximately 3000 lb), substitute numerical values and evaluate v:

$$v=\sqrt{\frac{2(6.292\times10^{18}\text{ J})}{1.4\times10^3\text{ kg}}}\approx\boxed{9.5\times10^7\text{ m/s}}$$

As expected, this result (4.2×10^8 m/s) is greater than the speed of light (and thus incorrect). Use of the nonrelativistic expression for kinetic energy is not justified.

74 • If a black hole and a "normal" star orbit each other, gases from the normal star falling into the black hole can have their temperature increased by millions of degrees due to frictional heating. When the gases are heated that much, they begin to radiate light in the X-ray region of the electromagnetic spectrum (high-energy light photons). Cygnus X-1, the second strongest known X-ray source in the sky, is thought to be one such binary system; it radiates at an

estimated power of 4×10^{31} W. If we assume that 1.0 percent of the in-falling mass escapes as X ray energy, at what rate is the black hole gaining mass?

Picture the Problem We can differentiate the mass-energy equation to obtain an expression for the rate at which the black hole gains energy.

Using the mass-energy relationship, express the energy radiated by the black hole:

$$E = (0.010)mc^2$$

Differentiate this expression to obtain an expression for the rate at which the black hole is radiating energy:

$$\frac{dE}{dt} = \frac{d}{dt}\left[(0.010)mc^2\right] = (0.010)c^2\,\frac{dm}{dt}$$

Solving for dm/dt yields:

$$\frac{dm}{dt} = \frac{dE/dt}{(0.010)c^2}$$

Substitute numerical values and evaluate dm/dt:

$$\frac{dm}{dt} = \frac{4\times10^{31}\ \text{watt}}{(0.010)\left(2.998\times10^{8}\ \text{m/s}\right)^2} \approx \boxed{4\times10^{16}\ \text{kg/s}}$$

75 • [SSM] You are designing the fuel requirements for a small fusion electric-generating plant. Assume 33% conversion to electric energy. For the deuterium–tritium (D–T) fusion reaction in Example 7-18, calculate the number of reactions per second that are necessary to generate 1.00 kW of electric power.

Picture the Problem The number of reactions per second is given by the ratio of the power generated to the energy released per reaction. The number of reactions that must take place to produce a given amount of energy is the ratio of the energy per second (power) to the energy released per second.

In Example 7-18 it is shown that the energy per reaction is 17.59 MeV. Convert this energy to joules:

$$17.59\,\text{MeV} = (17.59\,\text{MeV})\left(1.602\times10^{-19}\ \text{J/eV}\right) = 28.18\times10^{-13}\ \text{J}$$

Assuming 33% conversion to electric energy, the number of reactions per second is:

$$\frac{1000\,\text{J/s}}{(0.33)\left(28.18\times10^{-13}\ \text{J/reaction}\right)} \approx \boxed{1.1\times10^{15}\ \text{reactions/s}}$$

76 • Use Table 7-1 to calculate the energy needed to remove one neutron from a stationary alpha particle, leaving a stationary helion plus a neutron with a kinetic energy of 1.5 MeV.

Picture the Problem The energy required for this reaction is the sum of 1.5 MeV and the difference between the rest energy of ^{4}He and the sum of the rest energies of a helion (^{3}He) and a neutron.

The required energy is the sum of the energy required to remove the neutron and the kinetic energy of the neutron:

$$E_{\text{total}} = E + K_{\text{n}} \quad (1)$$

Express the reaction:

$$^4\text{He} \rightarrow {}^3\text{He} + \text{n}$$

From Table 7-1, the rest energy of a neutron is: 939.565 MeV

From Table 7-1, the rest energy of ^{4}He is: 3727.379 MeV

From Table 7-1, the rest energy of ^{3}He is: 2808.391 MeV

The energy required to remove the neutron is the difference between the sum of the rest energies of ^{3}He and the neutron and the rest energy of the alpha particle:

$$E = [(2808.391 + 939.565) - 3727.379]\ \text{MeV} = 20.577\ \text{MeV}$$

Substitute numerical values in equation (1) and evaluate E_{total}:

$$E_{\text{total}} = 20.577\ \text{MeV} + 1.5\ \text{MeV} = \boxed{22.1\ \text{MeV}}$$

77 • A free neutron can decay into a proton plus an electron and an electron antineutrino [an electron antineutrino (symbol $\overline{\nu}_{\text{e}}$) is a nearly massless elementary particle]: $\text{n} \rightarrow \text{p} + \text{e}^- + \overline{\nu}_{\text{e}}$. Use Table 7-1 to calculate the energy released during this reaction.

Picture the Problem The energy released during this reaction is the difference between the rest energy of a neutron and the sum of the rest energies of a proton and an electron.

The rest energy of a proton is: 938.272 MeV

The rest energy of an electron (Table 7-1) is: 0.511 MeV

The rest energy of a neutron (Table 7-1) is: 939.565 MeV

Substitute numerical values to find the difference in the rest energy of a neutron and the sum of the rest energies of a positron and an electron:

$$E = [939.565 - (938.272 + 0.511)]\text{ MeV} = \boxed{0.782\text{ MeV}}$$

78 •• During one type of nuclear fusion reaction, two deuterons combine to produce an alpha particle. (*a*) How much energy is released during this reaction? (*b*) How many such reactions must take place per second to produce 1 kW of power?

Picture the Problem The reaction is $^2\text{H} + ^2\text{H} \rightarrow ^4\text{He} + E$. The energy released in this reaction is the difference between twice the rest energy of ^{2}H and the rest energy of ^{4}He. The number of reactions that must take place to produce a given amount of energy is the ratio of the energy per second (power) to the energy released per reaction. See Table 7-1 for the rest energies of the particles.

(*a*) The rest energy of ^{4}He is: 3727.379 MeV

The rest energy of a deuteron, ^{2}H, is: 1875.613 MeV

The energy released in the reaction is:

$$E = [2(1875.613) - 3727.379]\text{ MeV} = 23.847\text{ MeV} \times \frac{1.6022\times10^{-19}\text{ J}}{\text{eV}} = 3.821\times10^{-12}\text{ J} = \boxed{3.82\times10^{-12}\text{ J}}$$

(*b*) The number of reactions per second is:

$$\frac{1.00\times10^{3}\text{ J/s}}{3.820\times10^{-12}\text{ J/reaction}} = \boxed{2.62\times10^{14}\text{ reactions/s}}$$

79 •• A large nuclear power plant produces 1000 MW of electrical power by nuclear fission. (*a*) By how many kilograms does the mass of the nuclear fuel decrease by in one year? (Assume an efficiency of 33 percent for a nuclear power plant.) (*b*) In a coal-burning power plant, each kilogram of coal releases 31 MJ of

thermal energy when burned. How many kilograms of coal are needed each year for a 1000-MW coal-burning power plant? (Assume an efficiency of 38 percent for a coal-burning power plant.)

Picture the Problem The annual consumption of matter by the fission plant is the ratio of its annual energy output to the square of the speed of light. The annual consumption of coal in a coal-burning power plant is the ratio of its annual energy output to energy per unit mass of the coal.

(*a*) The yearly consumption of matter is given by:

$$\Delta m = \frac{E}{\varepsilon c^2}$$

where E is the energy to be generated and ε is the efficiency of the plant.

Because the energy to be generated is the product of the power output of the plant and the elapsed time:

$$\Delta m = \frac{P\Delta t}{\varepsilon c^2} \qquad (1)$$

Substitute numerical values and evaluate Δm:

$$\Delta m = \frac{(1000\text{ MW})\left(1\text{ y}\times\dfrac{3.156\times10^7\text{ s}}{\text{y}}\right)}{(0.33)(2.998\times10^8\text{ m/s})^2} = \boxed{1.1\text{ kg}}$$

(*b*) For a coal-burning power plant, equation (1) becomes:

$$\Delta m_{\text{coal}} = \frac{P\Delta t}{\varepsilon\left(\dfrac{\text{energy released}}{\text{unit mass}}\right)}$$

Substitute numerical values and evaluate Δm_{coal}:

$$\Delta m_{\text{coal}} = \frac{(1000\text{ MW})\left(1\text{ y}\times\dfrac{3.156\times10^7\text{ s}}{\text{y}}\right)}{(0.38)(31\text{ MJ/kg})} = \boxed{2.7\times10^9\text{ kg}}$$

Remarks: 2.7×10^9 kg is approximately 3 million tons!

Quantization of Energy

80 •• A mass on the end of a spring with a force constant of 1000 N/kg oscillates at a frequency of 2.5 oscillations per second. (*a*) Determine the quantum number, *n*, of the state it is in if it has a total energy of 10 J. (*b*) What is its ground state energy?

Picture the Problem The energy number n of a state whose energy is E is given by $E = \left(n + \tfrac{1}{2}\right)hf$ where h is Planck's constant and f is the frequency of the state.

(*a*) The energy of the vibrational state is given by:

$$E = \left(n + \tfrac{1}{2}\right)hf$$

or, because we expect n to be very large,

$$E \approx nhf \Rightarrow n = \frac{E}{hf}$$

Substitute numerical values and evaluate n:

$$n = \frac{10\ \text{J}}{\left(6.63 \times 10^{-34}\ \text{J}\cdot\text{s}\right)\left(2.5\ \text{s}^{-1}\right)} = \boxed{6.0 \times 10^{33}}$$

(*b*) The ground state energy of the oscillator is the energy of the system when $n = 0$:

$$E_0 = \tfrac{1}{2}hf$$

Substitute numerical values and evaluate E_0:

$$E_0 = \tfrac{1}{2}\left(6.63 \times 10^{-34}\ \text{J}\cdot\text{s}\right)\left(2.5\ \text{s}^{-1}\right) = \boxed{8.3 \times 10^{-34}\ \text{J}}$$

81 •• Repeat Problem 80, but consider instead an atom in a solid vibrating at a frequency of 1.00×10^{14} oscillations per second and having a total energy of 2.7 eV.

Picture the Problem The energy number n of a state whose energy is E is given by $E = \left(n + \tfrac{1}{2}\right)hf$ where h is Planck's constant and f is the frequency of the state.

(*a*) The energy of the vibrational state is given by:

$$E = \left(n + \tfrac{1}{2}\right)hf \Rightarrow n = \frac{E}{hf} - \frac{1}{2}$$

Substitute numerical values and evaluate n:

$$n = \frac{2.7\ \text{eV} \times \dfrac{1.602 \times 10^{-19}\ \text{J}}{\text{eV}}}{\left(6.63 \times 10^{-34}\ \text{J}\cdot\text{s}\right)\left(10^{14}\ \text{s}^{-1}\right)} - \frac{1}{2} = \boxed{6}$$

(*b*) The ground state energy of the oscillator is the energy of the system when $n = 0$:

$$E_0 = \tfrac{1}{2}hf$$

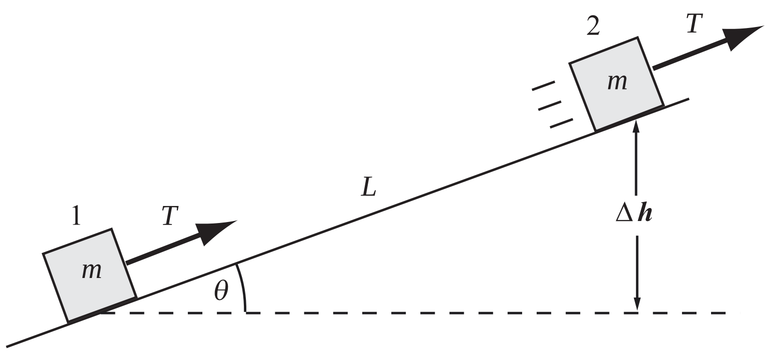
Substitute numerical values and evaluate E_0:

$$E_0 = \tfrac{1}{2}\left(6.63\times10^{-34}\ \text{J}\cdot\text{s}\right)\left(10^{14}\ \text{s}^{-1}\right)$$
$$= 3.315\times10^{-20}\ \text{J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}}$$
$$= \boxed{0.21\,\text{eV}}$$

General Problems

82 • A block of mass *m*, starting from rest, is pulled up a frictionless inclined plane that makes an angle θ with the horizontal by a string parallel to the plane. The tension in the string is *T*. After traveling a distance *L*, the speed of the block is v_f. Derive an expression for work done by the tension force.

Picture the Problem Let the system consist of the block, Earth, and the incline. Then the tension in the string is an external force that will do work to change the energy of the system. Because the incline is frictionless; the work done by the tension in the string as it displaces the block on the incline is equal to the sum of the changes in the kinetic and gravitational potential energies.



Relate the work done on the block by the tension force to the changes in the kinetic and gravitational potential energies of the block:

$$W_{\substack{\text{tension}\\\text{force}}} = W_{\text{ext}} = \Delta U + \Delta K \qquad (1)$$

Referring to the figure, express the change in the potential energy of the block as it moves from position 1 to position 2:

$$\Delta U = mg\Delta h = mgL\sin\theta$$

Because the block starts from rest:

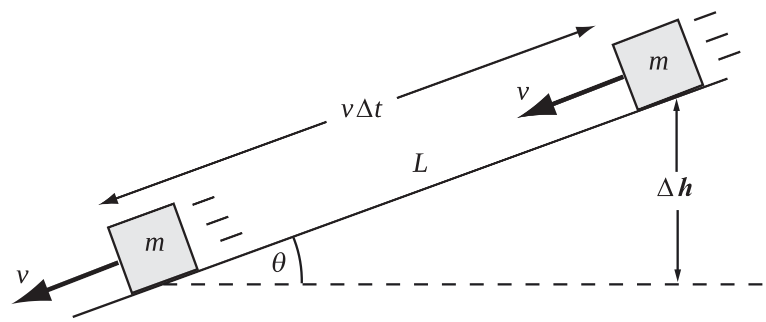
$$\Delta K = K_2 = \tfrac{1}{2}mv_f^2$$

Substitute for ΔU and ΔK in equation (1) to obtain:

$$W_{\substack{\text{tension}\\\text{force}}} = \boxed{mgL\sin\theta + \tfrac{1}{2}mv_f^2}$$

83 • A block of mass *m* slides with constant speed *v* down a plane inclined at angle θ with the horizontal. Derive an expression for the energy dissipated by friction during the time interval Δt.

Picture the Problem Let the system include Earth, the block, and the inclined plane. Then there are no external forces to do work on the system and $W_{\text{ext}} = 0$. Apply the work-energy theorem with friction to find an expression for the energy dissipated by friction.



Apply the work-energy theorem with friction to the block:

$$W_{\text{ext}} = \Delta K + \Delta U + \Delta E_{\text{therm}} = 0$$

Because the velocity of the block is constant, $\Delta K = 0$ and:

$$\Delta E_{\text{therm}} = -\Delta U = -mg\Delta h$$

In time Δt the block slides a distance $v\Delta t$. From the figure:

$$\Delta h = -v\Delta t \sin\theta$$

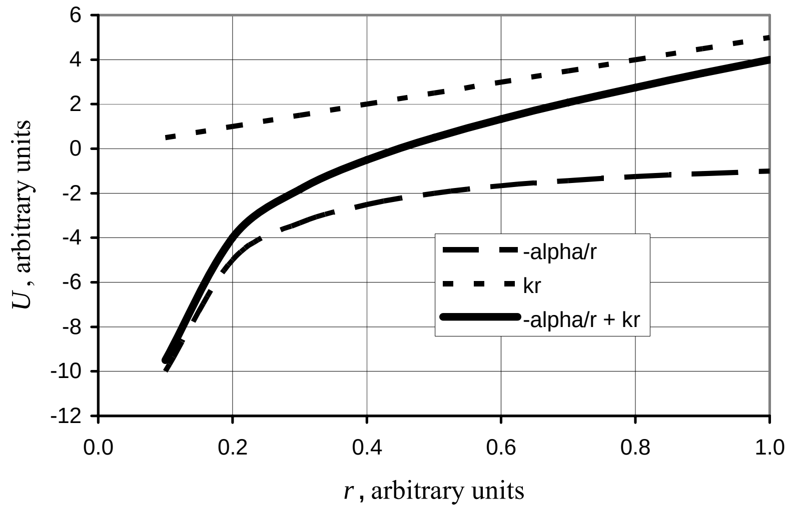
Substitute for Δh to obtain:

$$\Delta E_{\text{therm}} = \boxed{mgv\Delta t \sin\theta}$$

84 • In particle physics, the potential energy associated with a pair of quarks bound together by the strong nuclear force is in one particular theoretical model written as the following function: $U(r) = -(\alpha/r) + kr$, where k and α are positive constants, and r is the distance of separation between the two quarks. (*a*) Sketch the general shape of the potential-energy function. (*b*) What is a general form for the force each quark exerts on the other? (*c*) At the two extremes of very small and very large values of *r*, what does the force simplify to?

Picture the Problem The force between the two quarks is given by $F = -\dfrac{dU(r)}{dr}$.

(*a*) The following graph was plotted using a spreadsheet program. α was set equal to 1 and k was set equal to 5.



(*b*) F is given by:

$$F = -\frac{dU(r)}{dr}$$

Substitute for $U(r)$ and evaluate F to obtain:

$$F = -\frac{d}{dr}\left(-\frac{\alpha}{r} + kr\right) = \boxed{-\frac{\alpha}{r^2} + k}$$

(*c*) For $r >> 1$:

$$F_{r>>1} \to \boxed{k}$$

For $r << 1$:

$$F_{r<<1} \to \boxed{-\frac{\alpha}{r^2}}$$

85 • **[SSM]** You are in charge of ″solar-energizing″ your grandfather's farm. At the farm's location, an average of 1.0 kW/m^2 reaches the surface during the daylight hours on a clear day. If this could be converted at 25% efficiency to electric energy, how large a collection area would you need to run a 4.0-hp irrigation water pump during the daylight hours?

Picture the Problem The solar constant is the average energy per unit area and per unit time reaching the upper atmosphere. This physical quantity can be thought of as the power per unit area and is known as *intensity*.

Letting I_{surface} represent the intensity of the solar radiation at the surface of Earth, express I_{surface} as a function of power and the area on which this energy is incident:

$$\varepsilon I_{\text{surface}} = \frac{P}{A} \Rightarrow A = \frac{P}{\varepsilon I_{\text{surface}}}$$

where ε is the efficiency of conversion to electric energy.

Substitute numerical values and evaluate A:

$$A = \frac{4.0\ \text{hp} \times \dfrac{746\ \text{W}}{\text{hp}}}{(0.25)\left(1.0\ \text{kW/m}^2\right)} = \boxed{12\ \text{m}^2}$$

86 •• The radiant energy from the Sun that reaches Earth's orbit is $1.35\ \text{kW/m}^2$. (*a*) Even when the Sun is directly overhead and under dry desert conditions, 25% of this energy is absorbed and/or reflected by the atmosphere before it reaches Earth's surface. If the average frequency of the electromagnetic radiation from the Sun is $5.5 \times 10^{14}\ \text{Hz}$, how many photons per second would be incident upon a 1.0-m^2 solar panel? (*b*) Suppose the efficiency of the panels for converting the radiant energy to electrical energy and delivering it is a highly efficient 10.0%. How large a solar panel is needed to supply the needs of a 5.0-hp solar-powered car (assuming the car runs directly off the solar panel and not batteries) during a race in Cairo at noon on March 21? (*c*) Assuming a more-realistic efficiency of 3.3% and panels capable of rotating to be always perpendicular to the sunlight, how large an array of solar panels is needed to supply the power needs of the International Space Station (ISS)? The ISS requires about 110 kW of continuous electric power.

Picture the Problem The number of photons n incident on a solar panel is related to the energy E of the incident radiation ($E = nhf$) and the intensity of the solar radiation is the rate at which it delivers energy per unit area.

(*a*) The number of photons n incident on the solar panel is related to the energy E of the radiation:

$$E = nhf \Rightarrow n = \frac{E}{hf} \qquad (1)$$

The intensity I of the radiation is given by:

$$I = \frac{P}{A} = \frac{E}{A\Delta t} \Rightarrow E = IA\Delta t$$

Substituting for E in equation (1) yields:

$$n = \frac{IA\Delta t}{hf}$$

The number of photons arriving per unit time is given by:

$$\frac{n}{\Delta t} = \frac{IA}{hf} \text{ or } \frac{n}{\Delta t} = \frac{\varepsilon I'A}{hf}$$

where I' is the unreduced solar constant and ε is the percentage of the energy absorbed.

Substitute numerical values and evaluate the number of photons arriving per unit time:

$$\frac{n}{\Delta t} = \frac{(0.75)\left(1.35\ \text{kW/m}^2\right)\left(1.0\ \text{m}^2\right)}{\left(6.63 \times 10^{-34}\ \text{J}\cdot\text{s}\right)\left(5.5 \times 10^{14}\ \text{s}^{-1}\right)} = \boxed{2.8 \times 10^{21}\ \text{s}^{-1}}$$

(*b*) The effective intensity of the radiation is given by:

$$I=\frac{P}{\varepsilon A}\Rightarrow A=\frac{P}{\varepsilon I} \qquad (2)$$

where ε is the efficiency of energy conversion.

Substitute numerical values and evaluate *A*:

$$A=\frac{5.0\,\text{hp}\times\dfrac{746\,\text{W}}{\text{hp}}}{(0.10)(1.35\,\text{kW/m}^2)}=\boxed{28\,\text{m}^2}$$

(*c*) Substitute numerical values in equation (2) to obtain:

$$A=\frac{110\,\text{kW}}{(0.033)(1.35\,\text{kW/m}^2)}=\boxed{2.5\times10^3\,\text{m}^2}$$

87 •• In 1964, after the 1250-kg jet-powered car *Spirit of America* lost its parachute and went out of control during a run at Bonneville Salt Flats, Utah, it left skid marks about 8.00 km long. (This earned a place in the Guinness Book of World Records for longest skid marks.) (*a*) If the car was moving initially at a speed of about 800 km/h, and was still going at about 300 km/h when it crashed into a brine pond, estimate the coefficient of kinetic friction μ_k. (*b*) What was the kinetic energy of the car 60 s after the skid began?

Picture the Problem Let the system include Earth and the *Spirit of America*. Then there are no external forces to do work on the car and $W_{ext}=0$. We can use the work-energy theorem for problems with kinetic friction to relate the coefficient of kinetic friction to the given information. A constant-acceleration equation will yield the car's velocity when 60 s have elapsed.

(*a*) Apply the work-energy theorem with friction to relate the coefficient of kinetic friction μ_k to the initial and final kinetic energies of the car:

$$W_{\text{ext}}=\Delta K+\Delta U+\Delta E_{\text{therm}}=0$$

or

$$\tfrac{1}{2}mv_f^2-\tfrac{1}{2}mv_i^2+\mu_k mg\Delta s=0$$

Solving for μ_k yields:

$$\mu_k=\frac{v_i^2-v_f^2}{2g\Delta s}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k=\frac{\left[\left(800\dfrac{\text{km}}{\text{h}}\right)^2-\left(300\dfrac{\text{km}}{\text{h}}\right)^2\right]\times\left(\dfrac{1\,\text{h}}{3600\,\text{s}}\right)^2}{2(9.81\,\text{m/s}^2)(8.00\,\text{km})}=\boxed{0.270}$$

(*b*) The kinetic energy of the car as a function of its speed is:

$$K = \tfrac{1}{2}mv^2 \quad (1)$$

Using a constant-acceleration equation, relate the speed of the car to its acceleration, initial speed, and the elapsed time:

$$v = v_0 + at \quad (2)$$

Express the braking force acting on the car:

$$F_{\text{net}} = -f_{\text{k}} = -\mu_{\text{k}}mg = ma$$

Solving for *a* yields:

$$a = -\mu_{\text{k}}g$$

Substitute for *a* in equation (2) to obtain:

$$v = v_0 - \mu_{\text{k}}gt$$

Substituting for *v* in equation (1) yields an expression for the kinetic energy of car as a function of the time it has been skidding:

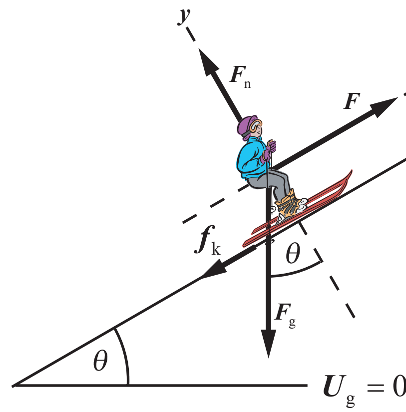
$$K(t) = \tfrac{1}{2}m(v_0 - \mu_{\text{k}}gt)^2$$

Substitute numerical values and evaluate $K(60\text{ s})$:

$$K(60\,\text{s}) = \tfrac{1}{2}(1250\,\text{kg})\left[800\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}} - (0.270)(9.81\,\text{m/s}^2)(60\,\text{s})\right]^2 = \boxed{2.5\,\text{MJ}}$$

88 •• A T-bar tow is planned in a new ski area. At any one time, it will be required, to pull a maximum of 80 skiers up a 600-m slope inclined at 15° above the horizontal at a speed of 2.50 m/s. The coefficient of kinetic friction between the skiers skis and the snow is typically 0.060. As the manager of the facility, what motor power should you request of the construction contractor if the mass of the average skier is 75.0 kg. Assume you want to be ready for any emergency and will order a motor whose power rating is 50% larger than the bare minimum.

Picture the Problem The free-body diagram shows the forces acting on a skier as he/she is towed up the slope at constant speed. We can apply the work-energy theorem to find the minimum rate at which the motor will have to supply energy to tow the skiers up an incline whose length is ℓ.



Apply the work-energy theorem to the skiers:

$$W_\text{ext} = \Delta E_\text{mech} + \Delta E_\text{therm} = \Delta K + \Delta U_\text{g} + \Delta E_\text{therm}$$

Because $\Delta K = 0$, $\Delta E_\text{therm} = f_\text{k}\ell$, and $\Delta U_\text{g} = m_\text{tot} g\ell\sin\theta$:

$$W_\text{ext} = m_\text{tot} g\ell\sin\theta + f_\text{k}\ell \qquad (1)$$

The external work done by the electric motor is given by:

$$W_\text{ext} = P_\text{min}\Delta t = P_\text{min}\frac{\ell}{v}$$

where v is the speed with which the skiers are towed up the incline.

The kinetic friction force is given by:

$$f_\text{k} = \mu_\text{k} F_\text{n} = \mu_\text{k} m_\text{tot} g\cos\theta$$

Substituting for W_ext and f_k in equation (1) yields:

$$P_\text{min}\frac{\ell}{v} = m_\text{tot} g\ell\sin\theta + \mu_\text{k} m_\text{tot} g\cos\theta$$

Solve for P_min to obtain:

$$P_\text{min} = m_\text{tot} gv(\sin\theta + \mu_\text{k}\cos\theta)$$

Because you want a safety factor of 50%, the power output of the motor you should order should be 150% of P_min:

$$P = 1.5 m_\text{tot} gv(\sin\theta + \mu_\text{k}\cos\theta)$$

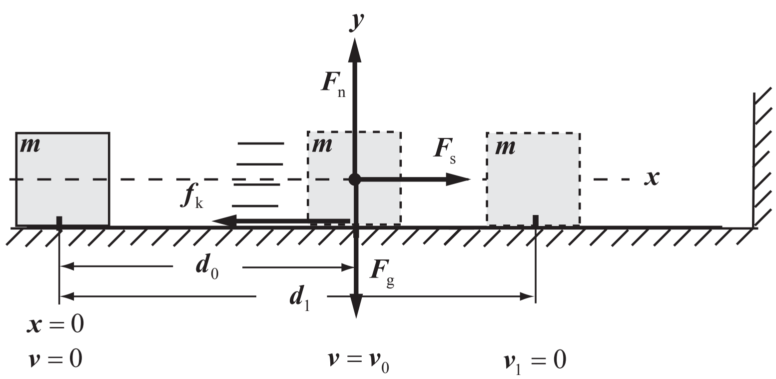
Substitute numerical values and evaluate P:

$$P = (1.5)(80)(75.0\,\text{kg})(9.81\,\text{m/s}^2)(2.50\,\text{m/s})[\sin 15.0° + (0.060)\cos 15.0°]$$
$$= \boxed{70\,\text{kW}}$$

Remarks: We could have solved this problem using Newton's second law.

89 •• A box of mass m on the floor is connected to a horizontal spring of force constant k (Figure 7-52). The coefficient of kinetic friction between the box and the floor is μ_k. The other end of the spring is connected to a wall. The spring is initially unstressed. If the box is pulled away from the wall a distance d_0 and released, the box slides toward the wall. Assume the box does not slide so far that the coils of the spring touch. (*a*) Obtain an expression for the distance d_1 the box slides before it first comes to a stop, (*b*) Assuming $d_1 > d_0$, obtain an expression for the speed of the box when it has slid a distance d_0 following the release. (*c*) Obtain the special value of μ_k such that $d_1 = d_0$.

Picture the Problem Let the system include Earth, the box, and the surface on which the box slides and apply the work-energy theorem for problems with kinetic friction to the box to derive the expressions for distance the box slides and the speed of the box when it first reaches its equilibrium position. The pictorial representation summarizes the salient features of this problem.



(*a*) Apply the work-energy theorem for problems with kinetic friction to the box as it moves from $x = 0$ to $x = d_1$ to obtain:

$$W_{\text{ext}} = \Delta E_{\text{sys}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}}$$

or, because $W_{\text{ext}} = \Delta K = \Delta U_g = 0$, $\Delta E_{\text{therm}} = f_k \Delta x$, and $\Delta E_{\text{mech}} = \Delta U_s$,

$$\Delta U_s + f_k \Delta x = 0$$

Substitute for ΔU_s and Δx to obtain:

$$\tfrac{1}{2}k(d_1 - d_0)^2 - \tfrac{1}{2}kd_0^2 + f_k d_1 = 0 \qquad (1)$$

Apply $\sum F_y = 0$ to the box to obtain: $F_n - F_g = 0 \Rightarrow F_n = F_g = mg$

f_k is given by: $f_k = \mu_k F_n = \mu_k mg$

Substituting for f_k in equation (1) yields: $\frac{1}{2}k(d_1 - d_0)^2 - \frac{1}{2}kd_0^2 + \mu_k mgd_1 = 0$

Solve for d_1 to obtain: $d_1 = \boxed{2d_0 - \frac{2\mu_k mg}{k}}$

(*b*) Apply the work-energy theorem to the box as it moves from $x = 0$ to $x = d_0$ to obtain: $W_{ext} = \Delta E_{sys} = \Delta E_{mech} + \Delta E_{therm}$
or, because $W_{ext} = \Delta U_g = 0$,
$\Delta K + \Delta U_s + \Delta E_{therm} = 0$

Noting that $K_0 = U_{s,f} = 0$, substitute for ΔK, ΔU_s, and ΔE_{therm} to obtain: $\frac{1}{2}mv_0^2 - \frac{1}{2}kd_0^2 + f_k d_0 = 0$

Substituting the expression for f_k obtained in (*a*) yields: $\frac{1}{2}mv_0^2 - \frac{1}{2}kd_0^2 + \mu_k mgd_0 = 0$

Solving for $\boldsymbol{v}_0$ yields: $v_0 = \boxed{\sqrt{\frac{k}{m}d_0^2 - 2\mu_k gd_0}}$

(*c*) Let $d_1 = d_0$ in the expression for d_1 derived in (*a*) to obtain: $d_0 = 2d_0 - \frac{2\mu_k mg}{k} \Rightarrow \mu_k = \boxed{\frac{kd_0}{2mg}}$

Remarks: You can obtain the same Part (*c*) result by setting $\boldsymbol{v}_0 = 0$ in the expression derived in Part (*b*).

90 •• You operate a small grain elevator near Champaign, Illinois. One of your silos uses a bucket elevator that carries a full load of 800 kg through a vertical distance of 40 m. (A bucket elevator works with a continuous belt, like a conveyor belt.) (*a*) What is the power provided by the electric motor powering the bucket elevator when the bucket elevator ascends with a full load at a speed of 2.3 m/s? (*b*) Assuming the motor is 85% efficient, how much does it cost you to run this elevator, per day, assuming it runs 60 percent of the time between 7:00 A.M. and 7:00 P.M. with and average load of 85 percent of a full load? Assume the cost of electric energy in your location is 15 cents per kilowatt hour.

Picture the Problem The power provided by a motor that is delivering sufficient energy to exert a force $\vec{F}$ on a load which it is moving at a speed $\vec{v}$ is $\vec{F} \cdot \vec{v}$.

(*a*) The power provided by the motor is given by:

$P = \vec{F} \cdot \vec{v} = Fv\cos\theta$

or, because $\vec{F}$ and $\vec{v}$ are in the same direction, $P = Fv$ (1)

Because the elevator is ascending with constant speed, the required force is:

$F = m_{\text{load}}g$

Substitute for F in equation (1) to obtain:

$P = m_{\text{load}}gv$

Substitute numerical values and evaluate P:

$$P = (800\,\text{kg})(9.81\,\text{m/s}^2)(2.3\,\text{m/s}) = 18.05\,\text{kW} = \boxed{18\,\text{kW}}$$

(*b*) The daily cost of operating the elevator is given by:

$C_{\text{daily}} = E_{\text{used}}c$ (2)

where c is the per unit cost of the energy.

The energy used by the motor is:

$$E_{\text{used}} = \frac{P_{\text{motor}}}{\varepsilon}\Delta t$$

where ε is the efficiency of the motor and Δt is the number of hours the elevator operates daily.

Substituting for E_{used} in equation (2) yields:

$$C_{\text{daily}} = \frac{P_{\text{motor}}\Delta tc}{\varepsilon}$$

Substitute numerical values and evaluate C_{daily}:

$$C_{\text{daily}} = \frac{(18.05\,\text{kW})(12\,\text{h} \times 0.60)\left(\frac{\$0.15}{\text{kWh}}\right)}{0.85} = \boxed{\$22.93}$$

91 •• To reduce the power requirement of elevator motors, elevators are counterbalanced with weights connected to the elevator by a cable that runs over a pulley at the top of the elevator shaft. Neglect any effects of friction in the pulley. If a 1200-kg elevator that carries a maximum load of 800 kg is counterbalanced with a mass of 1500 kg, (*a*) what is the power provided by the motor when the elevator ascends fully loaded at a speed of 2.3 m/s? (*b*) How

much power is provided by the motor when the elevator ascends at 2.3 m/s without a load?

Picture the Problem The power provided by a motor that is delivering sufficient energy to exert a force $\vec{F}$ on a load which it is moving at a speed $\vec{v}$ is $\vec{F}\cdot\vec{v}$.The counterweight does negative work and the power of the motor is reduced from that required with no counterbalance.

(*a*) The power provided by the motor is given by:

$$P = \vec{F}\cdot\vec{v} = Fv\cos\theta$$

or, because $\vec{F}$ and $\vec{v}$ are in the same direction,

$$P = Fv \qquad (1)$$

Because the elevator is counterbalanced and ascending with constant speed, the tension in the support cable(s) is:

$$F = (m_{\text{elev}} + m_{\text{load}} - m_{\text{cw}})g$$

Substitute for F in equation (1) to obtain:

$$P = (m_{\text{elev}} + m_{\text{load}} - m_{\text{cw}})gv$$

Substitute numerical values and evaluate P:

$$P = (1200\,\text{kg} + 800\,\text{kg} - 1500\,\text{kg})(9.81\,\text{m/s}^2)(2.3\,\text{m/s}) = 11.28\,\text{kW} = \boxed{11\,\text{kW}}$$

(*b*) Without a load:

$$F = (m_{\text{elev}} - m_{\text{cw}})g$$

and

$$P = Fv = (m_{\text{elev}} - m_{\text{cw}})gv$$

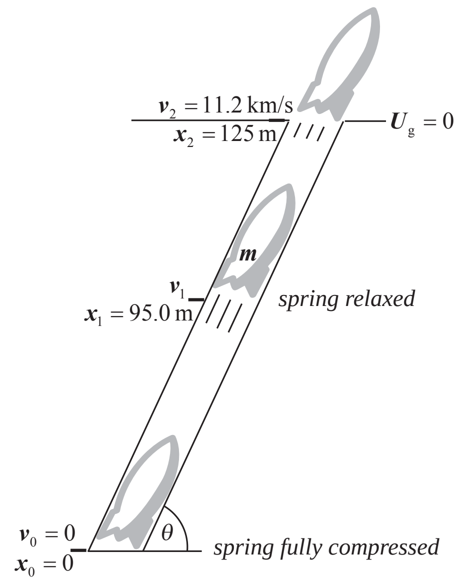
Substitute numerical values and evaluate P:

$$P = (1200\,\text{kg} - 1500\,\text{kg})(9.81\,\text{m/s}^2)(2.3\,\text{m/s}) = -6.77\,\text{kW} = \boxed{-6.8\,\text{kW}}$$

92 •• In old science fiction movies, writers attempted to come up with novel ways of launching spacecraft toward the moon. In one hypothetical case, a screenwriter envisioned launching a moon probe from a deep, smooth tunnel, inclined at 65.0° above the horizontal. At the bottom of the tunnel a very stiff spring designed to launch the craft was anchored. The top of the spring, when the spring is unstressed, is 30.0 m from the upper end of the table. The screenwriter knew from his research that to reach the moon, the 318-kg probe should have a speed of at least 11.2 km/s when it exits the tunnel. If the spring is compressed by

95.0 m just before launch, what is the minimum value for its force constant to achieve a successful launch? Neglect friction with the tunnel walls and floor.

Picture the Problem Let the system consist of Earth, the spring, the tunnel, and the spacecraft and the zero of gravitational potential energy be at the surface of Earth. Then there are no external forces to do work on the system and $W_{ext} = 0$. We can use conservation of mechanical energy to find the minimum value of the force constant that will result in a successful launch. The pictorial representation summarizes the details of the launch. Note that the spacecraft slows somewhat over the last 30 m of its launch.



(*a*) Apply conservation of mechanical energy to the spacecraft as it moves from $x = x_0$ to $x = x_2$ to obtain:

$$W_{ext} = \Delta E_{mech}$$

or, because $W_{ext} = 0$,

$$\Delta E_{mech} = 0 \qquad (1)$$

The change in the mechanical energy of the system is:

$$\begin{aligned}\Delta E_{mech} &= \Delta K + \Delta U_g + \Delta U_s \\ &= K_2 - K_0 + U_{g,2} - U_{g,0} \\ &\quad + U_{s,2} - U_{s,0}\end{aligned}$$

Because $K_0 = U_{g,2} = U_{s,2} = 0$:

$$\Delta E_{mech} = K_2 - U_{g,0} - U_{s,0}$$

Substituting for K_2, $U_{g,0}$, and $U_{s,0}$ yields:

$$\begin{aligned}\Delta E_{mech} &= \tfrac{1}{2}mv_2^2 - (-mgx_2 \sin\theta) - \tfrac{1}{2}kx_1^2 \\ &= \tfrac{1}{2}mv_2^2 + mgx_2 \sin\theta - \tfrac{1}{2}kx_1^2\end{aligned}$$

Substituting for ΔE_{mech} in equation (1) yields:

$$\tfrac{1}{2}mv_2^2 + mgx_2 \sin\theta - \tfrac{1}{2}kx_1^2 = 0$$

Solving for k yields:

$$k = \frac{mv_2^2 + 2mgx_2 \sin\theta}{x_1^2}$$

Substitute numerical values and evaluate k:

$$k = \frac{(318\,\text{kg})(11.2\,\text{km/s})^2 + 2(318\,\text{kg})(9.81\,\text{m/s}^2)(125\,\text{m})\sin 65.0°}{(95.0\,\text{m})^2}$$

$$= \boxed{4.42\times10^3\ \text{kN/m}}$$

93 •• **[SSM]** In a volcanic eruption, a 2-kg piece of porous volcanic rock is thrown straight upward with an initial speed of 40 m/s. It travels upward a distance of 50 m before it begins to fall back to Earth. (*a*) What is the initial kinetic energy of the rock? (*b*) What is the increase in thermal energy due to air resistance during ascent? (*c*) If the increase in thermal energy due to air resistance on the way down is 70% of that on the way up, what is the speed of the rock when it returns to its initial position?

Picture the Problem Let the system consist of Earth, the rock and the air. Given this choice, there are no external forces to do work on the system and $W_{\text{ext}} = 0$. Choose $U_g = 0$ to be where the rock begins its upward motion. The initial kinetic energy of the rock is partially transformed into potential energy and partially dissipated by air resistance as the rock ascends. During its descent, its potential energy is partially transformed into kinetic energy and partially dissipated by air resistance.

(*a*) The initial kinetic energy of the rock is given by:

$$K_i = \tfrac{1}{2}mv_i^2$$

Substitute numerical values and evaluate K_i:

$$K_i = \tfrac{1}{2}(2.0\,\text{kg})(40\,\text{m/s})^2 = \boxed{1.6\,\text{kJ}}$$

(*b*) Apply the work-energy theorem with friction to relate the energies of the system as the rock ascends:

$$\Delta K + \Delta U + \Delta E_{\text{therm}} = 0$$

or, because $K_f = 0$,

$$-K_i + \Delta U + \Delta E_{\text{therm}} = 0$$

Solving for ΔE_{therm} yields:

$$\Delta E_{\text{therm}} = K_i - \Delta U$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{\text{therm}} = 1.6\,\text{kJ} - (2.0\,\text{kg})(9.81\,\text{m/s}^2)(50\,\text{m}) = 0.619\,\text{kJ} = \boxed{0.6\,\text{kJ}}$$

(*c*) Apply the work-energy theorem with friction to relate the energies of the system as the rock descends:

$$\Delta K + \Delta U + 0.70\Delta E_{\text{therm}} = 0$$

Because $K_i = U_f = 0$:

$$K_f - U_i + 0.70\Delta E_{\text{therm}} = 0$$

Substitute for the energies to obtain:

$$\tfrac{1}{2}mv_f^2 - mgh + 0.70\Delta E_{\text{therm}} = 0$$

Solve for v_f to obtain:

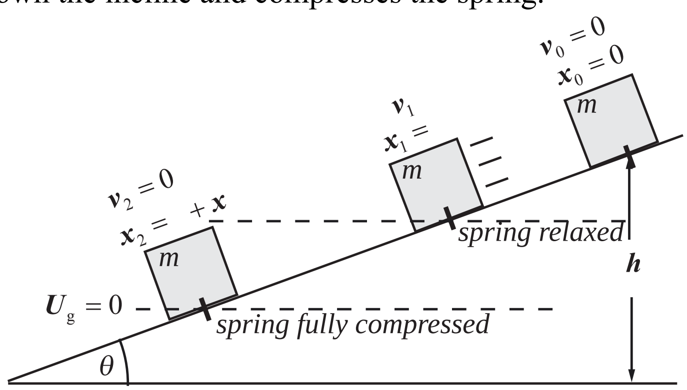
$$v_f = \sqrt{2gh - \frac{1.40\Delta E_{\text{therm}}}{m}}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{2\left(9.81\,\text{m/s}^2\right)\left(50\,\text{m}\right) - \frac{1.40\left(0.619\,\text{kJ}\right)}{2.0\,\text{kg}}} = \boxed{23\,\text{m/s}}$$

94 •• A block of mass *m* starts from rest at a height *h* and slides down a frictionless plane inclined at angle θ with the horizontal, as shown in Figure 7-53. The block strikes a spring of force constant *k*. Find the distance the spring is compressed when the block momentarily stops.

Picture the Problem Let the distance the block slides before striking the spring be ℓ. The pictorial representation shows the block at the top of the incline ($x_0 = 0$), just as it strikes the spring ($x_1 = \ell$), and the block against the fully compressed spring ($x_2 = \ell + x$). Let the block, spring, and Earth comprise the system. Then $W_{\text{ext}} = 0$. Let $U_g = 0$ where the spring is at maximum compression. We can apply the work-energy theorem to the block to relate the energies of the system as the block slides down the incline and compresses the spring.



Apply the work-energy theorem to the block from x_0 to x_2:

$$\Delta K + \Delta U_g + \Delta U_s = 0$$

or

$$\Delta K + U_{g,2} - U_{g,0} + U_{s,2} - U_{s,0} = 0$$

Because $\Delta K = U_{g,2} = U_{s,0} = 0$:

$$-U_{g,0} + U_{s,2} = 0$$

Substitute for each of these energy terms to obtain:

$$-mgh_0 + \tfrac{1}{2}kx^2 = 0 \qquad (1)$$

where x is the distance the spring compresses.

h_0 is given by:

$$h_0 = x_2 \sin\theta = (\ell + x)\sin\theta$$

Substitute for h_0 in equation (1) to obtain:

$$-mg(\ell + x)\sin\theta + \tfrac{1}{2}kx^2 = 0$$

Rewrite this equation explicitly as a quadratic equation to obtain:

$$x^2 - \frac{2mg\sin\theta}{k}x - \frac{2mg\ell\sin\theta}{k} = 0$$

Solving for x yields:

$$x = \boxed{\frac{mg}{k}\sin\theta + \sqrt{\left(\frac{mg}{k}\right)^2 \sin^2\theta + \frac{2mg\ell}{k}\sin\theta}}$$

Note that the negative sign between the two terms leads to a non-physical solution and has been ignored.

95 •• **[SSM]** A block of mass m is suspended from a wall bracket by a spring and is free to move vertically (Figure 7-54). The $+y$ direction is downward and the origin is at the position of the block when the spring is unstressed. (a) Show that the potential energy as a function of position may be expressed as $U = \tfrac{1}{2}ky^2 - mgy$, ($b$) Using a **spreadsheet** program or graphing calculator, make a graph of U as a function of y with k = 2 N/m and mg = 1 N. (c) Explain how this graph shows that there is a position of stable equilibrium for a positive value of y. Using the Part (a) expression for U, determine (symbolically) the value of y when the block is at its equilibrium position. (d) From the expression for U, find the net force acting on m at any position y. (e) The block is released from rest with the spring unstressed; if there is no friction, what is the maximum value of y that will be reached by the mass? Indicate y_{max} on your graph/spreadsheet.

Picture the Problem Let the system include Earth, the block and the spring. Given the potential energy function as a function of y, we can find the net force acting on the given system using $F = -dU/dy$. The maximum extension of the

spring; that is, the lowest position of the mass on its end, can be found by applying the work-energy theorem. The equilibrium position of the system can be found by applying the work-energy theorem with friction … as can the amount of thermal energy produced as the system oscillates to its equilibrium position. In Part (*c*), setting dU/dy equal to zero and solving the resulting equation for y will yield the value of y when the block is in its equilibrium position

(*a*) The potential energy of the oscillator is the sum of the gravitational potential energy of block and the energy stored in the stretched spring:

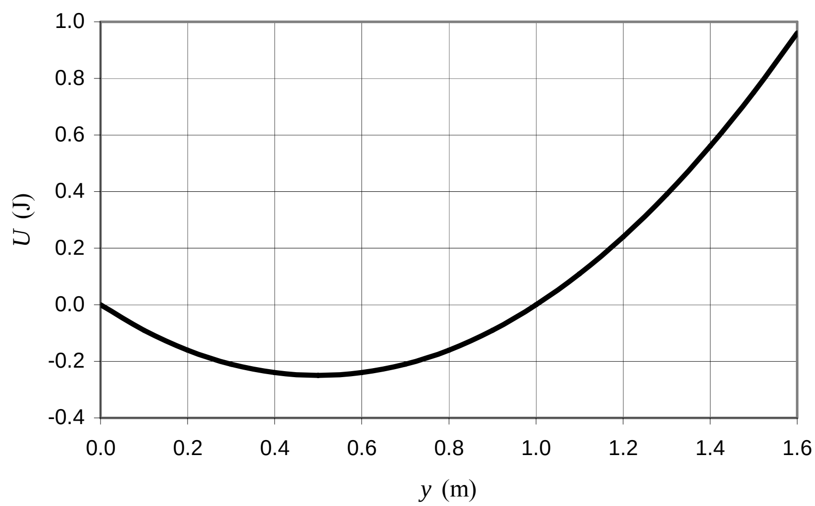
$$U = U_g + U_s$$

Letting the zero of gravitational potential energy be at the oscillator's equilibrium position yields:

$$U = \boxed{\tfrac{1}{2}ky^2 - mgy}$$

where y is the distance the spring is stretched.

(*b*) A graph of U as a function of y follows. Because k and m are not specified, k has been set equal to 2 and mg to 1.



(*c*) The fact that U is a minimum near $y = 0.5$ m tells us that this is a position of stable equilibrium.

Differentiate U with respect to y to obtain:

$$\frac{dU}{dy} = \frac{d}{dy}\left(\tfrac{1}{2}ky^2 - mgy\right) = ky - mg$$

Setting this expression equal to zero for extrema yields:

$$ky - mg = 0 \Rightarrow y = \boxed{\frac{mg}{k}}$$

(*d*) Evaluate the negative of the derivative of *U* with respect to *y*:

$$F = -\frac{dU}{dy} = -\frac{d}{dy}\left(\tfrac{1}{2}ky^2 - mgy\right)$$

$$= \boxed{-ky + mg}$$

(*e*) Apply conservation of energy to the movement of the mass from $y = 0$ to $y = y_{max}$:

$$\Delta K + \Delta U + \Delta E_{therm} = 0$$

Because $\Delta K = 0$ (the object starts from rest and is momentarily at rest at $y = y_{max}$) and (no friction), it follows that:

$$\Delta U = U(y_{max}) - U(0) = 0$$

Because $U(0) = 0$:

$$U(y_{max}) = 0 \Rightarrow \tfrac{1}{2}ky_{max}^2 - mgy_{max} = 0$$

Solve for y_{max} to obtain:

$$y_{max} = \boxed{\frac{2mg}{k}}$$

On the graph, y_{max} is at (1.0, 0.0).

96 •• A spring-loaded gun is cocked by compressing a short, strong spring by a distance *d*. It fires a signal flare of mass *m* directly upward. The flare has speed v_0 as it leaves the spring and is observed to rise to a maximum height *h* above the point where it leaves the spring. After it leaves the spring, effects of drag force by the air on the flare are significant. (Express answers in terms of *m*, v_0, *d*, *h*, and *g*.) (*a*) How much work is done on the spring during the compression? (*b*) What is the value of the force constant *k*? (*c*) Between the time of firing and the time at which maximum elevation is reached, how much mechanical energy is dissipated into thermal energy?

Picture the Problem The energy stored in the compressed spring is initially transformed into the kinetic energy of the signal flare and then into gravitational potential energy and thermal energy as the flare climbs to its maximum height. Let the system contain Earth, the air, and the flare so that $W_{ext} = 0$. We can use the work-energy theorem with friction in the analysis of the energy transformations during the motion of the flare.

(*a*) The work done on the spring in compressing it is equal to the kinetic energy of the flare at launch:

$$W_s = K_{i,\,flare} = \boxed{\tfrac{1}{2}mv_0^2}$$

(*b*) Ignoring changes in gravitational potential energy (that is, assume that the compression of the spring is small compared to the maximum elevation of the flare), apply the conservation of mechanical energy to the transformation that takes place as the spring decompresses and gives the flare its launch speed:

$$\Delta K + \Delta U_s = 0$$

or

$$K_f - K_i + U_{s,f} - U_{s,i} = 0$$

Because $K_i = U_{s,f} = 0$:

$$K_f - U_{s,i} = 0$$

Substitute for K_f and $U_{s,i}$ to obtain:

$$\tfrac{1}{2}mv_0^2 - \tfrac{1}{2}kd^2 = 0 \Rightarrow k = \boxed{\frac{mv_0^2}{d^2}}$$

(c) Apply the work-energy theorem with friction to the upward trajectory of the flare:

$$\Delta K + \Delta U_g + \Delta E_{therm} = 0$$

Solve for ΔE_{therm}:

$$\Delta E_{therm} = -\Delta K - \Delta U_g$$
$$= K_i - K_f + U_i - U_f$$

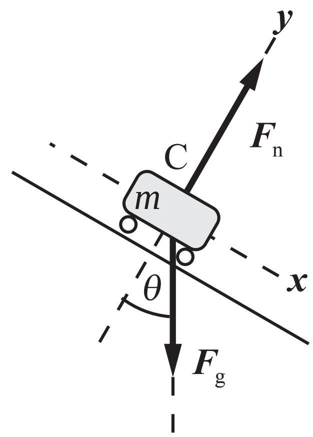
Because $K_f = U_i = 0$:

$$\Delta E_{therm} = \boxed{\tfrac{1}{2}mv_0^2 - mgh}$$

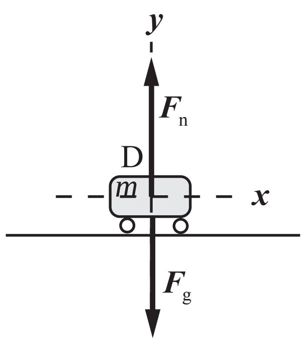
97 •• Your firm is designing a new roller-coaster ride. The permit process requires the calculation of forces and accelerations at various important locations on the ride. Each roller-coaster car will have a total mass (including passengers) of 500 kg and will travel freely along the winding frictionless track shown in Figure 7-55. Points A, E, and G are on horizontal straight sections, all at the same height of 10 m above the ground. Point C is at a height of 10 m above the ground on an inclined section of slope angle 30°. Point B is at the crest of a hill, while point D is at ground level at the bottom of a valley; the radius of curvature at both of these points is 20 m. Point F is at the middle of a banked horizontal curve with a radius of curvature of 30 m, and at the same height as points A, E, and G. At point A the speed of the car is 12 m/s. (*a*) If the car is just barely to make it over the hill at point B, what must be the height of point B above the ground? (*b*) If the car is to just barely make it over the hill at point B, what should be the magnitude of the force exerted by the track on the car at that point? (*c*) What will be the acceleration of the car at point C? (*d*) What will be the magnitude and direction of the force exerted by the track on the car at point D? (*e*) What will be the magnitude and direction of the force exerted by the track on the car at point F? (*f*) At point G a constant braking force is to be applied to the

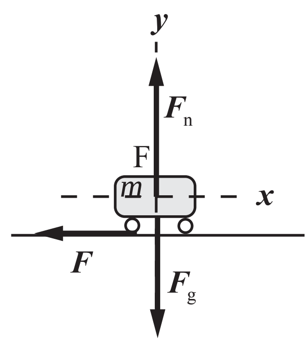
car, bringing it to a halt in a distance of 25 m. What is the magnitude of this required braking force?

Picture the Problem Let $U_D = 0$. Choose the system to include Earth, the track and the car. Then there are no external forces to do work on the system and change its energy and we can use Newton's second law and the work-energy theorem to describe the system's energy transformations to point G … and then the work-energy theorem with friction to determine the braking force that brings the car to a stop. The free-body diagram for point C is shown above.



The free-body diagrams for the rollercoaster cars at points D and F are shown below.





(*a*) Apply the work-energy theorem to the system's energy transformations between A and B:

$$\Delta K + \Delta U = 0$$

or

$$K_B - K_A + U_B - U_A = 0$$

If we assume that the car arrives at point B with $v_B = 0$, then:

$$-\tfrac{1}{2}mv_A^2 + mg\Delta h = 0 \Rightarrow \Delta h = \frac{v_A^2}{2g}$$

where Δh is the difference in elevation between A and B.

The height above the ground is given by:

$$h + \Delta h = h + \frac{v_A^2}{2g}$$

Substitute numerical values and evaluate $h + \Delta h$:

$$h+\Delta h = 10\,\text{m} + \frac{(12\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)} = 17.3\,\text{m}$$
$$= \boxed{17\,\text{m}}$$

(*b*) If the car just makes it to point B; i.e., if it gets there with $v_B = 0$, then the force exerted by the track on the car will be the normal force:

$$F_{\substack{\text{track}\\ \text{on car}}} = F_n = mg$$

Substitute numerical values and evaluate $F_{\substack{\text{track}\\ \text{on car}}}$:

$$F_{\substack{\text{track}\\ \text{on car}}} = (500\,\text{kg})(9.81\,\text{m/s}^2)$$
$$= \boxed{4.91\,\text{kN}}$$

(*c*) Apply $\sum F_x = ma_x$ to the car at point C (see the FBD) and solve for a:

$$mg\sin\theta = ma \Rightarrow a = g\sin\theta$$

Substitute numerical values and evaluate a:

$$a = (9.81\,\text{m/s}^2)\sin 30° = \boxed{4.9\,\text{m/s}^2}$$

(*d*) Apply $\sum F_y = ma_y$ to the car at point D (see the FBD) and solve for F_n:

$$F_n - mg = m\frac{v_D^2}{R} \Rightarrow F_n = mg + m\frac{v_D^2}{\text{R}}$$

Apply the work-energy theorem to the system's energy transformations between B and D:

$$\Delta K + \Delta U = 0$$
or
$$K_D - K_B + U_D - U_B = 0$$

Because $K_B = U_D = 0$:

$$K_D - U_B = 0$$

Substitute to obtain:

$$\tfrac{1}{2}mv_D^2 - mg(h+\Delta h) = 0$$

Solving for v_D^2 yields:

$$v_D^2 = 2g(h+\Delta h)$$

Substitute for v_D^2 in the expression for F_n and simplify to obtain:

$$F_n = mg + m\frac{v_D^2}{R} = mg + m\frac{2g(h+\Delta h)}{R}$$
$$= mg\left[1 + \frac{2(h+\Delta h)}{R}\right]$$

Substitute numerical values and evaluate F_n:

$$F_n = (500\,\text{kg})(9.81\,\text{m/s}^2)\left[1 + \frac{2(17.3\,\text{m})}{20\,\text{m}}\right] = \boxed{13\,\text{kN, directed upward.}}$$

(*e*) $\vec{F}$ has two components at point F; one horizontal (the inward force that the track exerts) and the other vertical (the normal force). Apply $\sum \vec{F} = m\vec{a}$ to the car at point F:

$$\sum F_y = F_n - mg = 0 \Rightarrow F_n = mg$$

and

$$\sum F_x = F_c = m\frac{v_F^2}{R}$$

Express the resultant of these two forces:

$$F = \sqrt{F_c^2 + F_n^2} = \sqrt{\left(m\frac{v_F^2}{R}\right)^2 + (mg)^2} = m\sqrt{\frac{v_F^4}{R^2} + g^2}$$

Substitute numerical values and evaluate F:

$$F = (500\,\text{kg})\sqrt{\frac{(12\,\text{m/s})^4}{(30\,\text{m})^2} + (9.81\,\text{m/s}^2)^2} = \boxed{5.5\,\text{kN}}$$

The angle the resultant makes with the x axis is given by:

$$\theta = \tan^{-1}\left(\frac{F_n}{F_c}\right) = \tan^{-1}\left(\frac{gR}{v_F^2}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left[\frac{(9.81\,\text{m/s}^2)(30\,\text{m})}{(12\,\text{m/s})^2}\right] = 63.9° = \boxed{64°}$$

(*f*) Apply the work-energy theorem with friction to the system's energy transformations between F and the car's stopping position:

$$-K_G + \Delta E_{\text{therm}} = 0$$

and

$$\Delta E_{\text{therm}} = K_G = \tfrac{1}{2}mv_G^2$$

The work done by friction is also given by:

$$\Delta E_{\text{therm}} = f\Delta s = F_{\text{brake}}d$$

where d is the stopping distance.

Equate the two expressions for ΔE_{therm} and solve for F_{brake}:

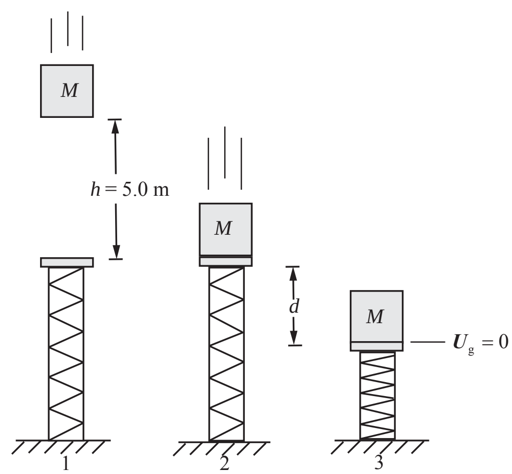
$$F_{\text{brake}} = \frac{mv_F^2}{2d}$$

Substitute numerical values and evaluate F_{brake}:

$$F_{\text{brake}} = \frac{(500\,\text{kg})(12\,\text{m/s})^2}{2(25\,\text{m})} = \boxed{1.4\,\text{kN}}$$

98 •• The cable of a 2000-kg elevator has broken, and the elevator is moving downward at a steady speed of 1.5 m/s. A safety braking system that works on friction prevents the downward speed from increasing. (*a*) At what rate is the braking system converting mechanical energy to thermal energy? (*b*) While the elevator is moving downward at 1.5 m/s, the braking system fails and the elevator is in free-fall for a distance of 5.0 m before hitting the top of a large safety spring with force constant of 1.5×10^4 N/m. After the elevator hits the top of the spring, find the distance *d* that the spring is compressed before the elevator is brought to rest.

Picture the Problem The rate of conversion of mechanical energy can be determined from $P = \vec{F} \cdot \vec{v}$. The pictorial representation shows the elevator moving downward just as it goes into freefall as state 1. In state 2 the elevator is moving faster and is about to strike the relaxed spring. The momentarily at rest elevator on the compressed spring is shown as state 3. Let $U_g = 0$ where the spring has its maximum compression and the system consist of Earth, the elevator and the spring. Then $W_{\text{ext}} = 0$ and we can apply conservation of mechanical energy to the analysis of the falling elevator and compressing spring.



(*a*) Express the rate of conversion of mechanical energy to thermal energy as a function of the speed of the elevator and braking force acting on it:

$$P = F_{\text{braking}} v_0$$

Because the elevator is moving with constant speed, the net force acting on it is zero and:

$$F_{\text{braking}} = Mg$$

Substitute for F_{braking} to obtain:

$$P = Mgv_0$$

Substitute numerical values and evaluate P:

$$P = (2000\,\text{kg})(9.81\,\text{m/s}^2)(1.5\,\text{m/s}) = \boxed{29\,\text{kW}}$$

(b) Apply the conservation of mechanical energy to the falling elevator and compressing spring:

$$\Delta K + \Delta U_{\text{g}} + \Delta U_{\text{s}} = 0$$

or

$$K_3 - K_1 + U_{\text{g},3} - U_{\text{g},1} + U_{\text{s},3} - U_{\text{s},1} = 0$$

Because $K_3 = U_{\text{g},3} = U_{\text{s},1} = 0$:

$$-\tfrac{1}{2}Mv_0^2 - Mg(h+d) + \tfrac{1}{2}kd^2 = 0$$

Rewrite this equation as a quadratic equation in d, the maximum compression of the spring:

$$d^2 - \left(\frac{2Mg}{k}\right)d - \frac{M}{k}\left(2gh + v_0^2\right) = 0$$

Solve for d to obtain:

$$d = \frac{Mg}{k} \pm \sqrt{\frac{M^2g^2}{k^2} + \frac{M}{k}\left(2gh + v_0^2\right)}$$

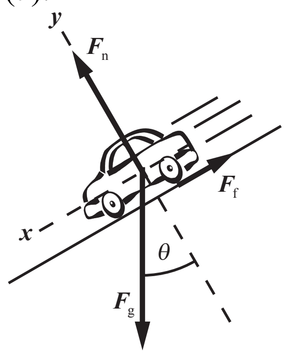
Substitute numerical values and evaluate d:

$$d = \frac{(2000\,\text{kg})(9.81\,\text{m/s}^2)}{1.5\times10^4\ \text{N/m}} + \sqrt{\frac{(2000\,\text{kg})^2(9.81\,\text{m/s}^2)^2}{(1.5\times10^4\ \text{N/m})^2} + \frac{2000\,\text{kg}}{1.5\times10^4\ \text{N/m}}\left[2(9.81\,\text{m/s}^2)(5.0\,\text{m}) + (1.5\,\text{m/s})^2\right]} = \boxed{5.2\,\text{m}}$$

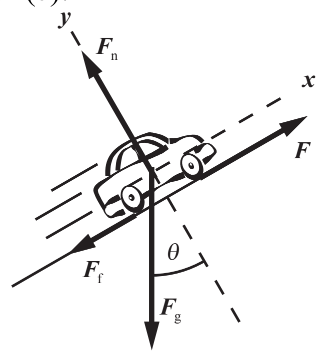
99 ••• [SSM] To measure the combined force of friction (rolling friction plus air drag) on a moving car, an automotive engineering team you are on turns off the engine and allows the car to coast down hills of known steepness. The team collects the following data: (1) On a 2.87° hill, the car can coast at a steady 20 m/s. (2) On a 5.74° hill, the steady coasting speed is 30 m/s. The total mass of the car is 1000 kg. (a) What is the magnitude of the combined force of friction at 20 m/s (F_{20}) and at 30 m/s (F_{30})? (b) How much power must the engine deliver to drive the car on a level road at steady speeds of 20 m/s (P_{20}) and 30 m/s (P_{30})? (c) The maximum power the engine can deliver is 40 kW. What is the angle of the steepest incline up which the car can maintain a steady 20 m/s? (d) Assume that the engine delivers the same total useful work from each liter of gas, no matter what the speed. At 20 m/s on a level road, the car gets 12.7 km/L. How many kilometers per liter does it get if it goes 30 m/s instead?

Picture the Problem We can use Newton's second law to determine the force of friction as a function of the angle of the hill for a given constant speed. The power output of the engine is given by $P = \vec{F}_f \cdot \vec{v}$.

FBD for (*a*):



FBD for (*c*):



(*a*) Apply $\sum F_x = ma_x$ to the car:

$$mg\sin\theta - F = 0 \Rightarrow F = mg\sin\theta$$

Evaluate F for the two speeds:

$$F_{20} = (1000\,\text{kg})(9.81\,\text{m/s}^2)\sin(2.87°) = \boxed{491\,\text{N}}$$

and

$$F_{30} = (1000\,\text{kg})(9.81\,\text{m/s}^2)\sin(5.74°) = \boxed{981\,\text{N}}$$

(*b*) The power an engine must deliver on a level road in order to overcome friction loss is given by:

$$P = F_f v$$

Evaluate this expression for v = 20 m/s and 30 m/s:

$$P_{20} = (491\,\text{N})(20\,\text{m/s}) = \boxed{9.8\,\text{kW}}$$

and

$$P_{30} = (981\,\text{N})(30\,\text{m/s}) = \boxed{29\,\text{kW}}$$

(*c*) Apply $\sum F_x = ma_x$ to the car:

$$\sum F_x = F - mg\sin\theta - F_f = 0$$

Solving for F yields:

$$F = mg\sin\theta + F_f$$

Relate F to the power output of the engine and the speed of the car:

$$F = \frac{P}{v}$$

Equate these expressions for F to obtain:

$$\frac{P}{v} = mg\sin\theta + F_{\text{f}}$$

Solving for θ yields:

$$\theta = \sin^{-1}\left[\frac{\frac{P}{v} - F_{\text{f}}}{mg}\right]$$

Substitute numerical values and evaluate θ for $F_{\text{f}} = F_{20}$:

$$\theta = \sin^{-1}\left[\frac{\frac{40\,\text{kW}}{20\,\text{m/s}} - 491\,\text{N}}{(1000\,\text{kg})(9.81\,\text{m/s}^2)}\right] = \boxed{8.8°}$$

(*d*) Express the equivalence of the work done by the engine in driving the car at the two speeds:

$$W_{\text{engine}} = F_{20}(\Delta s)_{20} = F_{30}(\Delta s)_{30}$$

Let ΔV represent the volume of fuel consumed by the engine driving the car on a level road and divide both sides of the work equation by ΔV to obtain:

$$F_{20}\frac{(\Delta s)_{20}}{\Delta V} = F_{30}\frac{(\Delta s)_{30}}{\Delta V}$$

Solve for $\frac{(\Delta s)_{30}}{\Delta V}$:

$$\frac{(\Delta s)_{30}}{\Delta V} = \frac{F_{20}}{F_{30}}\frac{(\Delta s)_{20}}{\Delta V}$$

Substitute numerical values and evaluate $\frac{(\Delta s)_{30}}{\Delta V}$:

$$\frac{(\Delta s)_{30}}{\Delta V} = \frac{491\,\text{N}}{981\,\text{N}}(12.7\,\text{km/L}) = \boxed{6.36\,\text{km/L}}$$

100 •• (*a*) Calculate the kinetic energy of a 1200-kg car moving at 50 km/h. (*b*) If friction (rolling friction and air drag) results in a retarding force of 300 N at a speed of 50 km/h, what is the minimum energy needed to move the car a distance of 300 m at a constant speed of 50 km/h?

Picture the Problem While on a horizontal surface, the work done by an automobile engine changes the kinetic energy of the car and does work against friction. These energy transformations are described by the work-energy theorem with friction. Let the system include Earth, the roadway, and the car *but not the car's engine*.

(*a*) The kinetic energy of the car is:

$$K = \tfrac{1}{2}(1200\,\text{kg})\left(50\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\right)^2 = \boxed{0.12\,\text{MJ}}$$

(*b*) The required energy equals the energy dissipated by friction:

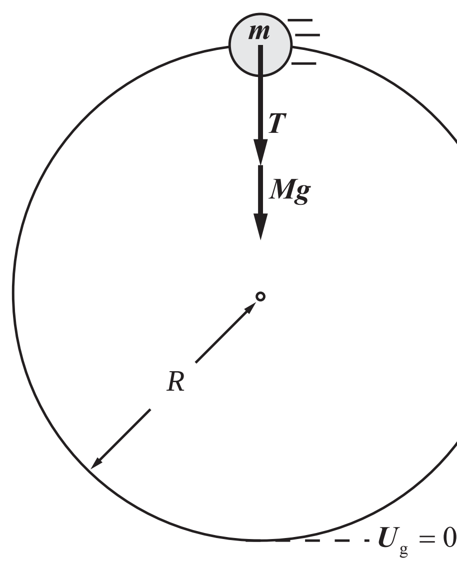
$$\Delta E_{\text{therm}} = f\Delta s$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{\text{therm}} = (300\,\text{N})(300\,\text{m}) = \boxed{90.0\,\text{kJ}}$$

101 ••• A pendulum consists of a string of length *L* with a small bob of mass *m*. The bob is held to the side with the string horizontal (see Figure 7-56). Then the bob is released from rest. At the lowest point of the swing, the string catches on a thin peg a distance *R* above the lowest point. Show that *R* must be smaller than 2*L*/5 if the string is to remain taut as the bob swings around the peg in a full circle.

Picture the Problem Assume that the bob is moving with speed *v* as it passes the top vertical point when looping around the peg. There are two forces acting on the bob: the tension in the string (if any) and the force of gravity, *Mg*; both point downward when the ball is in the topmost position. The minimum possible speed for the bob to pass the vertical occurs when the tension is 0; from this, gravity must supply the centripetal force required to keep the ball moving in a circle. We can use conservation of mechanical energy to relate *v* to *L* and *R*.



Express the condition that the bob swings around the peg in a full circle:

$$M\frac{v^2}{R} > Mg \Rightarrow \frac{v^2}{R} > g \qquad (1)$$

Use conservation of mechanical energy to relate the kinetic energy of the bob at the bottom of the loop to its potential energy at the top of its swing:

$$\tfrac{1}{2}Mv^2 = Mg(L-2R)$$

Solving for v^2 yields:

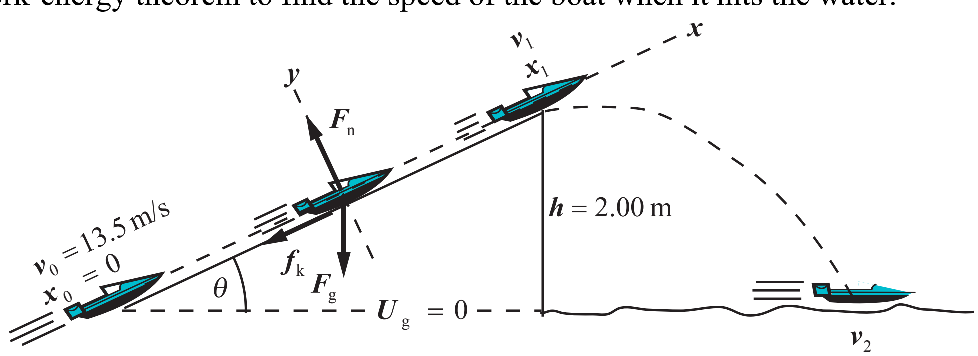
$$v^2 = 2g(L-2R)$$

Substitute for v^2 in equation (1) to obtain:

$$\frac{2g(L-2R)}{R} > g \Rightarrow R < \boxed{\frac{2}{5}L}$$

102 •• A 285-kg stunt boat is driven on the surface of a lake at a constant speed of 13.5 m/s toward a ramp, which is angled at 25.0° above the horizontal. The coefficient of friction between the boat bottom and the ramp's surface is 0.150, and the raised end of the ramp is 2.00 m above the water surface. (*a*) Assuming the engines are cut off when the boat hits the ramp, what is the speed of the boat as it leaves the ramp? (*b*) What is the speed of the boat when it strikes the water again? Neglect any effects due to air resistance.

Picture the Problem The pictorial representation summarizes the details of the problem. Let the system consist of Earth, the boat, and the ramp. Then no external forces do work on the system. We can use the work-energy theorem for problems with kinetic friction to find the speed of the boat at the top of the ramp and the work-energy theorem to find the speed of the boat when it hits the water.



(*a*) Apply the work-energy theorem to the boat as it slides up the ramp to obtain:

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm}$$

or, because $W_{ext} = 0$,

$$\Delta E_{mech} + \Delta E_{therm} = 0 \qquad (1)$$

ΔE_{mech} is given by:

$$\Delta E_{mech} = \Delta K + \Delta U_g = K_1 - K_0 + U_{g,1} - U_{g,0}$$

or, because $U_{g,0} = 0$,

$$\Delta E_{mech} = K_1 - K_0 + U_{g,1}$$

Substituting for K_1, K_0, and $U_{g,1}$ yields:

$$\Delta E_{\text{mech}} = \tfrac{1}{2}mv_1^2 - \tfrac{1}{2}mv_0^2 + mgh$$

ΔE_{therm} is given by:

$$\Delta E_{\text{therm}} = f_k x_1 = \mu_k F_n x_1$$

Because $F_n = mg\cos\theta$:

$$\Delta E_{\text{therm}} = \mu_k mgx_1\cos\theta$$

Substituting for ΔE_{mech} and ΔE_{therm} in equation (1) yields:

$$\tfrac{1}{2}mv_1^2 - \tfrac{1}{2}mv_0^2 + mgh + \mu_k mgx_1\cos\theta = 0$$

Referring to the pictorial representation, express x_1 in terms of h to obtain:

$$x_1 = \frac{h}{\sin\theta}$$

Substituting for x_1 yields:

$$\tfrac{1}{2}mv_1^2 - \tfrac{1}{2}mv_0^2 + mgh + \frac{\mu_k mgh\cos\theta}{\sin\theta} = 0$$

Solve for v_1 to obtain:

$$v_1 = \sqrt{v_0^2 - 2gh(1+\mu_k\cot\theta)}$$

Substitute numerical values and evaluate v_1:

$$\begin{aligned} v_1 &= \sqrt{(13.5\text{ m/s})^2 - 2(9.81\text{ m/s}^2)(2.00\text{ m})[1+(0.150)\cot(25.0°)]} \\ &= 11.42\text{ m/s} = \boxed{11.4\text{ m/s}} \end{aligned}$$

(*b*) Apply the work-kinetic energy theorem to the boat while it is airborne:

$$W_{\text{ext}} = \Delta K + \Delta U_g$$

or, because $W_{\text{ext}} = 0$,

$$\Delta K + \Delta U_g = 0$$

Substitute for ΔK and ΔU_g to obtain:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 - mgh = 0$$

Solving for v_2 yields:

$$v_2 = \sqrt{v_1^2 + 2gh}$$

Substitute numerical values and evaluate v_2:

$$v_2 = \sqrt{(11.42\text{ m/s})^2 + 2(9.81\text{ m/s}^2)(2.00\text{ m})} = \boxed{13.0\text{ m/s}}$$

103 •• A standard introductory-physics lab-experiment to examine the conservation of energy and Newton's laws is shown in Figure 7-57. A glider is set up on a linear air track and is attached by a string over a massless-frictionless pulley to a hanging weight. The mass of the glider is *M*, while the mass of the hanging weight is *m*. When the air supply to the air track is turned on, the track

becomes essentially frictionless. You then release the hanging weight and measure the speed of the glider after the weight has fallen a given distance (y). To show that the measured speed is the speed predicted by theory; (a) apply conservation of mechanical energy and calculate the speed as a function of y. To verify this calculation; (b) apply Newton's second and third laws directly by sketching a free-body diagram for each of the two masses and applying Newton's laws to find their accelerations. Then use kinematics to calculate the speed of the glider as a function of y.

Picture the Problem For Part (a), we'll let the system include the glider, track, weight, and Earth. The speeds of the glider and the falling weight will be the same while they are in motion. Let their common speed when they have moved a distance Y be v and let the zero of potential energy be at the elevation of the weight when it has fallen the distance Y. We can use conservation of mechanical energy to relate the speed of the glider (and the weight) to the distance the weight has fallen. In Part (b), we'll let the direction of motion be the x direction, the tension in the connecting string be T, and apply Newton's second law to the glider and the weight to find their common acceleration. Because this acceleration is constant, we can use a constant-acceleration equation to find their common speed when they have moved a distance Y.

(a) Apply the work-energy theorem to the system to obtain:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

or, because $W_{\text{ext}} = 0$,

$$K_{\text{f}} - K_{\text{i}} + U_{\text{f}} - U_{\text{i}} = 0$$

Because the system starts from rest and $U_{\text{f}} = 0$:

$$K_{\text{f}} - U_{\text{i}} = 0$$

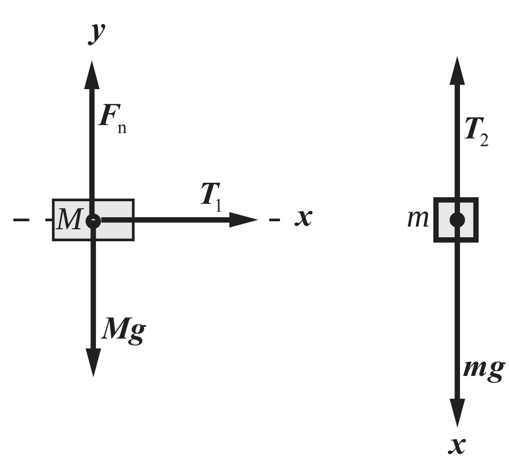
Substitute for K_{f} and U_{i} to obtain:

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}Mv^2 - mgY = 0$$

Solving for v yields:

$$v = \boxed{\sqrt{\frac{2mgY}{M+m}}}$$

(b) The free-body diagrams for the glider and the weight are shown to the right:



Apply Newton's 3rd law to obtain: $\left|\vec{T}_1\right| = \left|\vec{T}_2\right| = T$

Apply $\sum F_x = ma$ to the glider: $T = Ma$

Apply $\sum F_x = ma$ to the hanging weight: $mg - T = ma$

Add these equations to eliminate T and obtain: $mg = Ma + ma \Rightarrow a = g\dfrac{m}{m+M}$

Using a constant-acceleration equation, relate the speed of the glider to its initial speed and to the distance that the weight has fallen: $v^2 = v_0^2 + 2aY$
or, because $v_0 = 0$,
$v^2 = 2aY$

Substitute for a and solve for v to obtain: $v = \boxed{\sqrt{\dfrac{2mgY}{M+m}}}$, the same result we obtained in Part (a).

104 •• In one model of a person jogging, the energy expended is assumed to go into accelerating and decelerating the feet and the lower portions of the legs. If the jogging speed is v then the maximum speed of the foot and lower leg is about $2v$. (From the moment a foot leaves the ground, to the moment it next contacts the ground, the foot travels nearly twice as far as the torso, so it must be going, on average, nearly twice as fast as the torso.) If the mass of the foot and lower portion of a leg is m, the energy needed to accelerate the foot and lower portion of a leg from rest to speed $2v$ is $\frac{1}{2}m(2v)^2 = 2mv^2$, and the same energy is needed to decelerate this mass back to rest for the next stride. Assume that the mass of the foot and lower portion of a man's leg is 5.0 kg and that he jogs at a speed of 3.0 m/s with 1.0 m between one footfall and the next. The energy he must provide to each leg in each 2.0 m of travel is $2mv^2$, so the energy he must provide to both legs during each second of jogging is $6mv^2$. Calculate the rate of the man's energy expenditure using this model, assuming that his muscles have an efficiency of 20 percent.

Picture the Problem We're given $P = dW/dt$ and are asked to evaluate it under the assumed conditions.

We're given that the rate of energy expenditure by the man is: $P = 6mv^2$

Substitute numerical values and evaluate P: $P = 6(10\,\text{kg})(3.0\,\text{m/s})^2 = 540\,\text{W}$

Express the rate of energy expenditure P' assuming that his muscles have an efficiency of 20%:

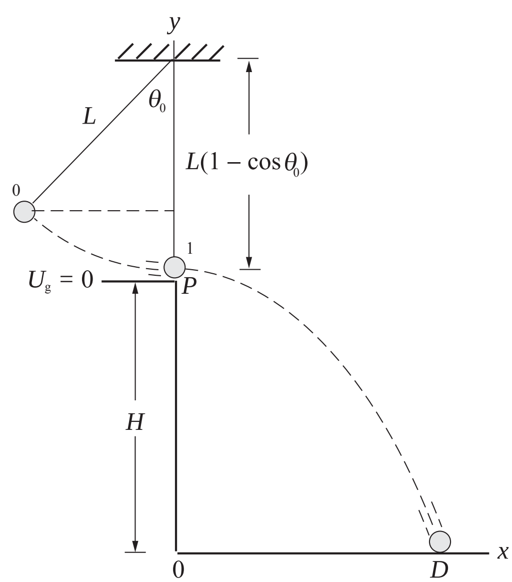
$$P = \tfrac{1}{5}P' \Rightarrow P' = 5P$$

Substitute numerical values and evaluate P':

$$P' = 5(540\ \text{W}) = \boxed{2.7\ \text{kW}}$$

105 •• **[SSM]** A high school teacher once suggested measuring the magnitude of free-fall acceleration by the following method: Hang a mass on a very fine thread (length L) to make a pendulum with the mass a height H above the floor when at its lowest point P. Pull the pendulum back so that the thread makes an angle θ_0 with the vertical. Just above point P, place a razor blade that is positioned to cut through the thread as the mass swings through point P. Once the thread is cut, the mass is projected horizontally, and hits the floor a horizontal distance D from point P. The idea was that the measurement of D as a function of θ_0 should somehow determine g. Apart from some obvious experimental difficulties, the experiment had one fatal flaw: D does not depend on g! Show that this is true, and that D depends only on the angle θ_0.

Picture the Problem The pictorial representation shows the bob swinging through an angle θ_0 before the thread is cut and the ball is launched horizontally. Let its speed at position 1 be v_1. We can use conservation of mechanical energy to relate v_1 to the change in the potential energy of the bob as it swings through the angle θ_0. We can find its flight time Δt from a constant-acceleration equation and then express D as the product of v_1 and Δt.



Relate the distance D traveled horizontally by the bob to its launch speed v_1 and time of flight Δt:

$$D = v_1\Delta t \qquad (1)$$

Use conservation of mechanical energy to relate its energies at positions 0 and 1:

$$K_1 - K_0 + U_1 - U_0 = 0$$

or, because $U_1 = K_0 = 0$,

$$K_1 - U_0 = 0$$

Substitute for K_1 and U_0 to obtain:

$$\tfrac{1}{2}mv_1^2 - mgL(1-\cos\theta_0) = 0$$

Solving for v_1 yields:

$$v_1 = \sqrt{2gL(1-\cos\theta_0)}$$

In the absence of air resistance, the horizontal and vertical motions of the bob are independent of each other and we can use a constant-acceleration equation to express the time of flight (the time to fall a distance H):

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $\Delta y = -H$, $a_y = -g$, and $v_{0y} = 0$,

$$-H = -\tfrac{1}{2}g(\Delta t)^2 \Rightarrow \Delta t = \sqrt{\frac{2H}{g}}$$

Substitute in equation (1) and simplify to obtain:

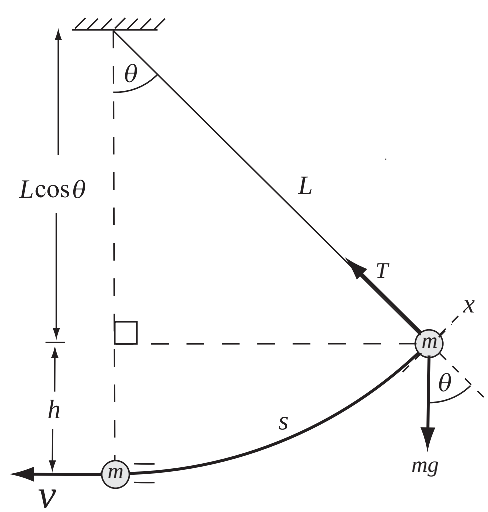
$$D = \sqrt{2gL(1-\cos\theta_0)}\sqrt{\frac{2H}{g}}$$

$$= \boxed{2\sqrt{HL(1-\cos\theta_0)}}$$

which shows that, while D depends on θ_0, it is independent of g.

106 ••• The bob of a pendulum of length L is pulled aside so that the string makes an angle θ_0 with the vertical, and the bob is then released. In Example 7-5, the conservation of energy was used to obtain the speed of the bob at the bottom of its swing. In this problem, you are to obtain the same result using Newton's second law. (*a*) Show that the tangential component of Newton's second law gives $dv/dt = -g \sin\theta$, where v is the speed and θ is the angle between the string and the vertical. (*b*) Show that v can be written $v = L\, d\theta/dt$. (*c*) Use this result and the chain rule for derivatives to obtain $\frac{dv}{dt} = \frac{dv}{d\theta}\frac{v}{L}$. (*d*) Combine the results of Parts (*a*) and (*c*) to obtain $v\, dv = -gL \sin\theta\, d\theta$. (*e*) Integrate the left side of the equation in Part (*d*) from $v = 0$ to the final speed v and the right side from $\theta = \theta_0$ to $\theta = 0$, and show that the result is equivalent to $v = \sqrt{2gh}$, where h is the original height of the bob above the bottom of its swing.

Picture the Problem The free-body diagram shows the forces acting on the pendulum bob. The application of Newton's second law leads directly to the required expression for the tangential acceleration. Recall that, provided θ is in radian measure, $s = L\theta$. Differentiation with respect to time produces the result called for in (*b*). The remaining parts of the problem simply require following



the directions for each part.

(a) Apply $\sum F_x = ma_x$ to the bob:

$$F_{\tan} = -mg\sin\theta = ma_{\tan}$$

Solving for $a_{\tan}$ yields:

$$a_{\tan} = dv/dt = \boxed{-g\sin\theta}$$

(b) Relate the arc distance s to the length of the pendulum L and the angle θ:

$$s = L\theta$$

Differentiate s with respect to time:

$$ds/dt = \boxed{v = Ld\theta/dt}$$

(c) Multiply $\dfrac{dv}{dt}$ by $\dfrac{d\theta}{d\theta}$ and substitute for $\dfrac{d\theta}{dt}$ from Part (b):

$$\frac{dv}{dt} = \frac{dv}{dt}\frac{d\theta}{d\theta} = \frac{dv}{d\theta}\frac{d\theta}{dt} = \boxed{\frac{dv}{d\theta}\left(\frac{v}{L}\right)}$$

(d) Equate the expressions for dv/dt from (a) and (c) to obtain:

$$\frac{dv}{d\theta}\left(\frac{v}{L}\right) = -g\sin\theta$$

Separating the variables yields:

$$vdv = \boxed{-gL\sin\theta\, d\theta}$$

(e) Integrate the left side of the equation in Part (d) from $v = 0$ to the final speed v and the right side from $\theta = \theta_0$ to $\theta = 0$:

$$\int_0^v vdv = \int_{\theta_0}^0 -gL\sin\theta\; d\theta$$

Integrate both sides of the equation to obtain:

$$\tfrac{1}{2}v^2 = gL(1-\cos\theta_0)$$

Note, from the figure, that $h = L(1-\cos\theta_0)$. Substitute to obtain:

$$\tfrac{1}{2}v^2 = gh \Rightarrow v = \boxed{\sqrt{2gh}}$$

107 ••• A rock climber is rappelling down the face of a cliff when his hold slips and he slides down over the rock face, supported only by the bungee cord he attached to the top of the cliff. The cliff face is in the form of a smooth quarter-cylinder with height (and radius) $H = 300$ m (Figure 7-58). Treat the bungee cord as a spring with force constant $k = 5.00$ N/m and unstressed length $L = 60.0$ m. The climber's mass is 85.0 kg. (a) Using a **spreadsheet** program, make a graph of the rock climber's potential energy as a function of s, his distance from the top of

the cliff *measured along the curved surface*. Use values of s between 60.0 m and 200 m. (*b*) His fall began when he was a distance s_i = 60.0 m from the top of the cliff, and ended when he was a distance s_f = 110 m from the top. Determine how much energy is dissipated by friction between the time he initially slipped and the time when he came to a stop.

Picture the Problem The potential energy of the climber is the sum of his gravitational potential energy and the potential energy stored in the spring-like bungee cord. Let θ be the angle which the position of the rock climber on the cliff face makes with a vertical axis and choose the zero of gravitational potential energy to be at the bottom of the cliff. We can use the definitions of U_g and U_{spring} to express the climber's total potential energy and the work-energy theorem for problems with friction to determine how energy is dissipated by friction between the time he initially slipped and finally came to a stop.

(*a*) The total potential energy of the climber is the sum of $U_{\substack{\text{bungee}\\\text{cord}}}$ and U_g:

$$U(s) = U_{\substack{\text{bungee}\\\text{cord}}} + U_g \qquad (1)$$

$U_{\substack{\text{bungee}\\\text{cord}}}$ is given by:

$$U_{\substack{\text{bungee}\\\text{cord}}} = \tfrac{1}{2}k(s-L)^2$$

U_g is given by:

$$U_g = Mgy = MgH\cos\theta = MgH\cos\left(\frac{s}{H}\right)$$

Substitute for $U_{\substack{\text{bungee}\\\text{cord}}}$ and U_g in equation (1) to obtain:

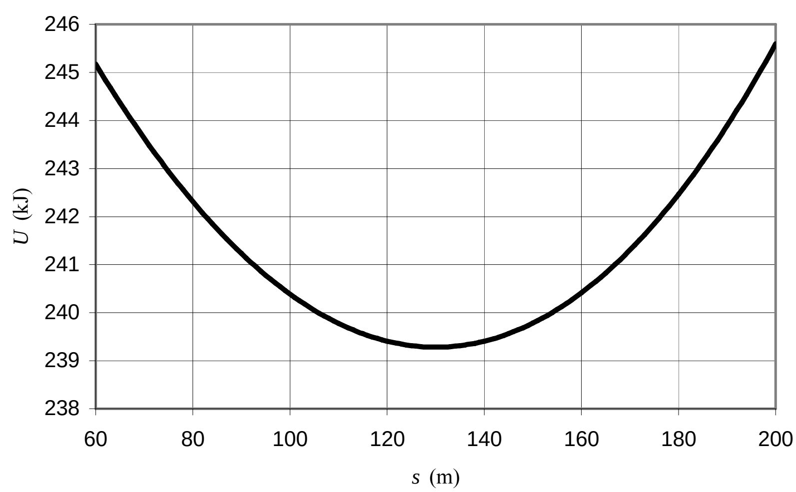
$$U(s) = \tfrac{1}{2}k(s-L)^2 + MgH\cos\left(\frac{s}{H}\right)$$

A spreadsheet solution is shown below. The constants used in the potential energy function and the formulas used to calculate the potential energy are as follows:

Cell	Content/Formula	Algebraic Form
B3	300	H
B4	5.00	k
B5	60.0	L
B6	85.0	M
B7	9.81	g
D11	60.0	s
D12	D11+1	$s+1$
E11	0.5*$B$4*(D11−$B$5)^2 +$B$6*$B$7*$B$3*(cos(D11/$B$3))	$\tfrac{1}{2}k(s-L)^2 + MgH\cos\left(\frac{s}{H}\right)$

	A	B	C	D	E
1					
2					
3	H =	300	m		
4	k =	5.00	N/m		
5	L =	60.0	m		
6	m =	85.0	kg		
7	g =	9.81	m/s^2		
8					
9				s	$U(s)$
10				(m)	(J)
11				60	2.452E+05
12				61	2.450E+05
13				62	2.448E+05
14				63	2.447E+05
15				64	2.445E+05
59				108	2.399E+05
60				109	2.398E+05
61				110	2.398E+05
62				111	2.397E+05
63				112	2.397E+05

The following graph was plotted using the data from columns D (s) and E ($U(s)$).



(b) Apply the work-kinetic energy theorem for problems with friction to the climber to obtain:

$$W_{\text{ext}} = \Delta K + \Delta U(s) + \Delta E_{\text{therm}}$$

or, because $W_{\text{ext}} = \Delta K = 0$,

$$\Delta U(s) + \Delta E_{\text{therm}} = 0$$

Solve for the energy dissipated by friction to obtain:

$$\Delta E_{\text{therm}} = -\Delta U(s) = -\left(U(110\text{ m}) - U(60.0\text{ m})\right) = -U(110\text{ m}) + U(60.0\text{ m})$$

Substituting for U(110 m) and U(60.0 m) and simplifying yields:

$$\begin{aligned}\Delta E_{\text{therm}} &= -\left[\tfrac{1}{2}k(110\text{ m} - L)^2 + MgH\cos\left(\frac{110\text{ m}}{H}\right)\right] \\ &\quad + \left[\tfrac{1}{2}k(60.0\text{ m} - L)^2 + MgH\cos\left(\frac{60.0\text{ m}}{H}\right)\right] \\ &= -\tfrac{1}{2}k(110\text{ m} - L)^2 - MgH\cos\left(\frac{110\text{ m}}{H}\right) + \tfrac{1}{2}k(60.0\text{ m} - L)^2 \\ &\quad + MgH\cos\left(\frac{60.0\text{ m}}{H}\right)\end{aligned}$$

Because L = 60.0 m, the third term is zero. Simplifying yields:

$$\begin{aligned}\Delta E_{\text{therm}} &= -\tfrac{1}{2}k(110\text{ m} - L)^2 - MgH\cos\left(\frac{110\text{ m}}{H}\right) + MgH\cos\left(\frac{60.0\text{ m}}{H}\right) \\ &= -\tfrac{1}{2}k(110\text{ m} - L)^2 - MgH\left[\cos\left(\frac{110\text{ m}}{H}\right) - \cos\left(\frac{60.0\text{ m}}{H}\right)\right]\end{aligned}$$

Substitute numerical values and evaluate ΔE_{therm}:

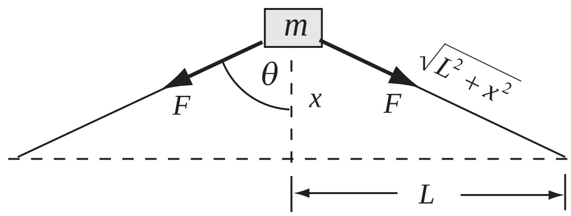
$$\begin{aligned}\Delta E_{\text{therm}} &= -\tfrac{1}{2}(5.00\text{ N/m})(110\text{ m} - 60.0\text{ m})^2 \\ &\quad - (85.0\text{ kg})(9.81\text{ m/s}^2)(300\text{ m})\left[\cos\left(\frac{110\text{ m}}{(300\text{ m})}\right) - \cos\left(\frac{60.0\text{ m}}{(300\text{ m})}\right)\right] \\ &\approx \boxed{5.4\text{ kJ}}\end{aligned}$$

Remarks: You can obtain this same result by examining the partial spreadsheet printout or the graph shown above.

108 ••• A block of wood (mass m) is connected to two massless springs, as shown in Figure 7-59. Each spring has unstressed length L and force constant k. (a) If the block is displaced a distance x, as shown, what is the change in the potential energy stored in the springs? (b) What is the magnitude of the force pulling the block back toward the equilibrium position? (c) Using a **spreadsheet** program or graphing calculator, make a graph of the potential energy U as a function of x for $0 \le x \le 0.20$ m. Assume k = 1.0 N/m, L = 0.10 m, and m = 1.0 kg. (d) If the block is displaced a distance x = 0.10 m and released, what is its speed as

it passes through the equilibrium point? Assume that the block is resting on a frictionless surface.

Picture the Problem The diagram shows the forces the springs exert on the block. Because the block is resting on a horizontal surface and they have no role in the motion of the block, the gravitational force and the normal force are not shown. The change in the potential energy stored in the springs is due to the elongation of both springs when the block is displaced a distance x from its equilibrium position and we can find ΔU using $\frac{1}{2}k(\Delta L)^2$. We can find the magnitude of the force pulling the block back toward its equilibrium position by finding the sum of the magnitudes of the y components of the forces exerted by the springs. In Part (d) we can use conservation of mechanical energy to find the speed of the block as it passes through its equilibrium position.



(a) Express the change in the potential energy stored in the springs when the block is displaced a distance x:

$$\Delta U = 2\left[\tfrac{1}{2}k(\Delta L)^2\right] = k(\Delta L)^2$$

where ΔL is the change in length of either spring.

Use the diagram to express ΔL:

$$\Delta L = \sqrt{L^2 + x^2} - L$$

Substitute for ΔL to obtain:

$$\Delta U = \boxed{k\left(\sqrt{L^2 + x^2} - L\right)^2}$$

(b) Sum the forces acting on the block to express $F_{\text{restoring}}$:

$$F_{\text{restoring}} = 2F\cos\theta = 2k\Delta L\cos\theta$$

$$= 2k\Delta L\frac{x}{\sqrt{L^2 + x^2}}$$

Substitute for ΔL to obtain:

$$F_{\text{restoring}} = 2k\left(\sqrt{L^2 + x^2} - L\right)\frac{x}{\sqrt{L^2 + x^2}}$$

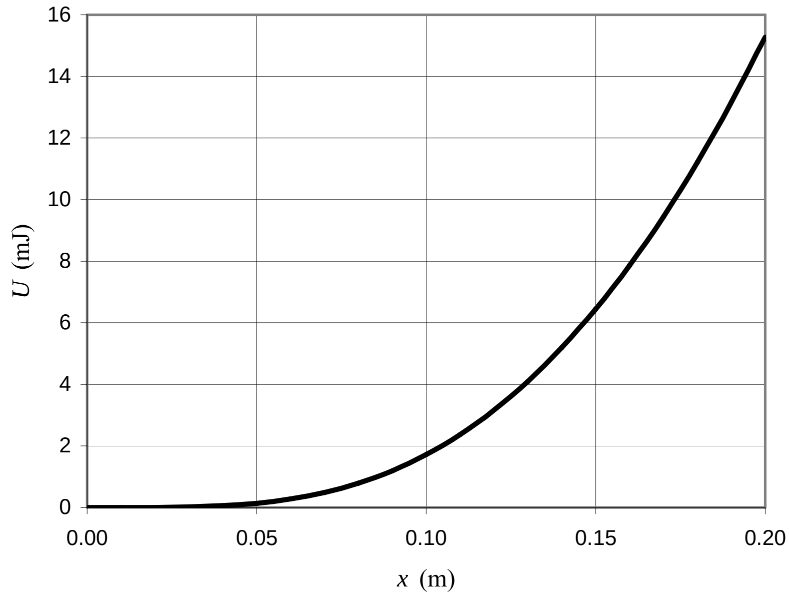
$$= \boxed{2kx\left(1 - \frac{L}{\sqrt{L^2 + x^2}}\right)}$$

(*c*) A spreadsheet program to calculate $U(x)$ is shown below. The constants used in the potential energy function and the formulas used to calculate the potential energy are as follows:

Cell	Content/Formula	Algebraic Form
B1	0.1	L
B2	1.0	k
B3	1.0	M
C8	C7+0.01	x
D7	\$B\$2*((C7^2+\$B\$1^2)^0.5−\$B\$1)^2	$U(x)$

	A	B	C	D
1	L =	0.1	m	
2	k =	1.0	N/m	
3	m =	1.0	kg	
4				
5			x	$U(x)$
6			(m)	(J)
7			0	0
8			0.01	2.49E−07
9			0.02	3.92E−06
10			0.03	1.94E−05
11			0.04	5.93E−05
12			0.05	1.39E−04
23			0.16	7.86E−03
24			0.17	9.45E−03
25			0.18	1.12E−02
26			0.19	1.32E−02
27			0.20	1.53E−02

The following graph was plotted using the data from columns C (x) and D ($U(x)$).



(d) Use conservation of mechanical energy to relate the kinetic energy of the block as it passes through the equilibrium position to the change in its potential energy as it returns to its equilibrium position:

$$K_{\text{equilibrium}} = \Delta U$$

or

$$\tfrac{1}{2}mv^2 = \Delta U \Rightarrow v = \sqrt{\frac{2\Delta U}{m}}$$

Substitute for ΔU and simplify to obtain:

$$v = \sqrt{\frac{2k\left(\sqrt{L^2 + x^2} - L\right)^2}{m}}$$

$$= \left(\sqrt{L^2 + x^2} - L\right)\sqrt{\frac{2k}{m}}$$

Substitute numerical values and evaluate v:

$$v = \left(\sqrt{(0.10\,\text{m})^2 + (0.10\,\text{m})^2} - 0.10\,\text{m}\right)\sqrt{\frac{2(1.0\,\text{N/m})}{1.0\,\text{kg}}} = \boxed{5.9\,\text{cm/s}}$$

Chapter 8
Conservation of Linear Momentum

Conceptual Problems

1 • **[SSM]** Show that if two particles have equal kinetic energies, the magnitudes of their momenta are equal only if they have the same mass.

Determine the Concept The kinetic energy of a particle, as a function of its momentum, is given by $K = p^2/2m$.

The kinetic energy of the particles is given by:

$$K_1 = \frac{p_1^2}{2m_1} \text{ and } K_2 = \frac{p_2^2}{2m_2}$$

Equate these kinetic energies to obtain:

$$\frac{p_1^2}{2m_1} = \frac{p_2^2}{2m_2}$$

Because the magnitudes of their momenta are equal:

$$\frac{1}{m_1} = \frac{1}{m_2} \text{ and } m_1 = \boxed{m_2}$$

2 • Particle A has twice the (magnitude) momentum and four times the kinetic energy of particle B. A also has four times the kinetic energy of B. What is the ratio of their masses (the mass of particle A to that of particle B)? Explain your reasoning.

Determine the Concept The kinetic energy of a particle, as a function of its momentum, is given by $K = p^2/2m$.

The kinetic energy of particle A is given by:

$$K_A = \frac{p_A^2}{2m_A} \Rightarrow m_A = \frac{p_A^2}{2K_A}$$

The kinetic energy of particle B is given by:

$$K_B = \frac{p_B^2}{2m_B} \Rightarrow m_B = \frac{p_B^2}{2K_B}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{m_A}{m_B} = \frac{\dfrac{p_A^2}{2K_A}}{\dfrac{p_B^2}{2K_B}} = \frac{K_B p_A^2}{K_A p_B^2} = \frac{K_B}{K_A}\left(\frac{p_A}{p_B}\right)^2$$

Because particle A has twice the (magnitude) momentum of particle B and four times as much kinetic energy:

$$\frac{m_A}{m_B} = \frac{K_B}{4K_B}\left(\frac{2p_B}{p_B}\right)^2 = \boxed{1}$$

3 • Using SI units, show that the units of momentum squared divided by those of mass is equivalent to the joule.

Determine the Concept The SI units of momentum are kg·m/s.

Express the ratio of the square of the units of momentum to the units of mass:

$$\frac{\left(\text{kg}\cdot\dfrac{\text{m}}{\text{s}}\right)^2}{\text{kg}}$$

Simplify to obtain:

$$\frac{\left(\text{kg}\cdot\dfrac{\text{m}}{\text{s}}\right)^2}{\text{kg}} = \frac{\text{kg}^2\cdot\dfrac{\text{m}^2}{\text{s}^2}}{\text{kg}} = \text{kg}\cdot\frac{\text{m}^2}{\text{s}^2} = \left(\text{kg}\cdot\frac{\text{m}}{\text{s}^2}\right)\cdot\text{m} = \text{N}\cdot\text{m} = \boxed{\text{J}}$$

4 • True or false:

(*a*) The total linear momentum of a system may be conserved even when the mechanical energy of the system is not.
(*b*) For the total linear momentum of a system to be conserved, there must be no external forces acting on the system.
(*c*) The velocity of the center of mass of a system changes only when there is a net external force on the system.

(*a*) True. Consider the collision of two objects of equal mass traveling in opposite directions with the same speed. Assume that they collide inelastically. The mechanical energy of the system is not conserved (it is transformed into other forms of energy), but the momentum of the system is the same after the collision as before the collision; that is, zero. Therefore, for any inelastic collision, the momentum of a system may be conserved even when mechanical energy is not.

(*b*) False. The *net* external force must be zero if the linear momentum of the system is to be conserved.

(*c*) True. This non-zero net force accelerates the center of mass. Hence its velocity changes.

5 • If a bullet is fired due west, explain how conservation of linear momentum enables you to predict that the recoil of the rifle be exactly due east. Is kinetic energy conserved here?

Determine the Concept The momentum of the bullet-gun system is initially zero. After firing, the bullet's momentum is directed west. Momentum conservation requires that the system's total momentum does not change, so the gun's momentum must be directed east. Kinetic energy is not conserved. Some of the initial chemical energy of the gun powder, for example, is transformed into thermal energy and sound energy.

6 • A child jumps from a small boat to a dock. Why does she have to jump with more effort than she would need if she were jumping through an identical displacement, but from a boulder to a tree stump?

Determine the Concept When she jumps from a boat to a dock, she must, in order for momentum to be conserved, give the boat a recoil momentum, that is, her forward momentum must be the same as the boat's backward momentum. When she jumps through an identical displacement from a boulder to a tree stump, the mass of the boulder plus Earth is so large that the momentum she imparts to them is essentially zero.

7 •• **[SSM]** Much early research in rocket motion was done by Robert Goddard, physics professor at Clark College in Worcester, Massachusetts. A quotation from a 1920 editorial in the *New York Times* illustrates the public opinion of his work: "That Professor Goddard with his 'chair' at Clark College and the countenance of the Smithsonian Institution does not know the relation between action and reaction, and the need to have something better than a vacuum against which to react—to say that would be absurd. Of course, he only seems to lack the knowledge ladled out daily in high schools." The belief that a rocket needs something to push against was a prevalent misconception before rockets in space were commonplace. Explain why that belief is wrong.

Determine the Concept In a way, the rocket does need something to push upon. It pushes the exhaust in one direction, and the exhaust pushes it in the opposite direction. However, the rocket does not push against the air. Another way to look at this is conservation of momentum. The momentum of the exhaust is equal and opposite to the momentum of the rocket, so momentum is conserved.

8 • Two identical bowling balls are moving with the same center-of-mass velocity, but one just slides down the alley without rotating, whereas the other rolls down the alley. Which ball has more kinetic energy?

Determine the Concept The kinetic energy of the sliding ball is $\frac{1}{2}mv_{\text{cm}}^2$. The kinetic energy of the rolling ball is $\frac{1}{2}mv_{\text{cm}}^2 + K_{\text{rel}}$, where K_{rel} is its kinetic energy

relative to its center of mass. Because the bowling balls are identical and have the same velocity, the rolling ball has more kinetic energy. There is no problem here because the relationship $K = p^2/2m$ is between the center of mass kinetic energy of the ball and its linear momentum.

9 • A philosopher tells you, ″Changing motion of objects is impossible. Forces always come in equal but opposite pairs. Therefore, all forces cancel out. Because forces cancel, the momenta of objects can never be changed.″ Answer his argument.

Determine the Concept Think of someone pushing a box across a floor. Her push on the box is equal but opposite to the push of the box on her, but the action and reaction forces act on *different objects*. Newton's second law is that the sum of the forces acting on the box equals the rate of change of momentum of the box. This sum does not include the force of the box on her.

10 • A moving object collides with a stationary object. Is it possible for both objects to be at rest immediately after the collision? (Assume any external forces acting on this two-object system are negligibly small.) Is it possible for one object to be at rest immediately after the collision? Explain.

Determine the Concept It's not possible for both to remain at rest after the collision, as that wouldn't satisfy the requirement that momentum is conserved. It is possible for one to remain at rest. This is what happens for a one-dimensional collision of two identical particles colliding elastically.

11 • Several researchers in physics education claim that part of the cause of physical misconceptions amongst students comes from special effects they observe in cartoons and movies. Using the conservation of linear momentum, how would you explain to a class of high school physics students what is conceptually wrong with a superhero hovering at rest in midair while tossing massive objects such as cars at villains? Does this action violate conservation of energy as well? Explain.

Determine the Concept Hovering in midair while tossing objects violates the conservation of linear momentum! To throw something forward requires being pushed backward. Superheroes are not depicted as experiencing this backward motion that is predicted by conservation of linear momentum. This action does not violate the conservation of energy.

12 •• A struggling physics student asks ″If only external forces can cause the center of mass of a system of particles to accelerate, how can a car move? Doesn't the car's engine supply the force needed to accelerate the car? ″ Explain what external agent produces the force that accelerates the car, and explain how the engine makes that agent do so.

Determine the Concept There is only one force which can cause the car to move forward–the friction of the road! The car's engine causes the tires to rotate, but if the road were frictionless (as is closely approximated by icy conditions) the wheels would simply spin without the car moving anywhere. Because of friction, the car's tire pushes backwards against the road and the frictional force acting on the tire pushes it forward. This may seem odd, as we tend to think of friction as being a retarding force only, but it is true.

13 •• When we push on the brake pedal to slow down a car, a brake pad is pressed against the rotor so that the friction of the pad slows the rotation of the rotor and thus the rotation of the wheel. However, the friction of the pad against the rotor can't be the force that slows the car down, because it is an internal force—both the rotor and the wheel are parts of the car, so any forces between them are internal, not external, forces. What external agent exerts the force that slows down the car? Give a detailed explanation of how this force operates.

Determine the Concept The frictional force by the road on the tire causes the car to slow. Normally the wheel is rotating at just the right speed so both the road and the tread in contact with the road are moving backward at the same speed relative to the car. By stepping on the brake pedal, you slow the rotation rate of the wheel. The tread in contact with the road is no longer moving as fast, relative to the car, as the road. To oppose the tendency to skid, the tread exerts a forward frictional force on the road and the road exerts an equal and opposite force on the tread.

14 • Explain why a circus performer falling into a safety net can survive unharmed, while a circus performer falling from the same height onto the hard concrete floor suffers serious injury or death. Base your explanation on the impulse-momentum theorem.

Determine the Concept Because $\Delta p = F\Delta t$ is constant, the safety net reduces the force acting on the performer by increasing the time Δt during which the slowing force acts.

15 •• **[SSM]** In Problem 14, estimate the ratio of the collision time with the safety net to the collision time with the concrete for the performer falling from a height of 25 m. *Hint: Use the procedure outlined in Step 4 of the Problem-Solving Strategy located in Section 8-3.*

Determine the Concept The stopping time for the performer is the ratio of the distance traveled during stopping to the average speed during stopping.

Letting d_{net} be the distance the net gives on impact, d_{concrete} the distance the concrete gives, and $v_{\text{av, with net}}$ and $v_{\text{av,without net}}$ the average speeds during stopping, express the ratio of the impact times:

$$r=\frac{\Delta t_{\text{net}}}{\Delta t_{\text{concrete}}}=\frac{\dfrac{d_{\text{net}}}{v_{\text{av, with net}}}}{\dfrac{d_{\text{concrete}}}{v_{\text{av, without net}}}} \qquad (1)$$

Assuming constant acceleration, the average speed of the performer during stopping is given by:

$$v_{\text{av}}=\frac{v_{\text{f}}+v}{2}$$

or, because $v_{\text{f}}=0$ in both cases,

$$v_{\text{av}}=\tfrac{1}{2}v$$

where v is the impact speed.

Substituting in equation (1) and simplifying yields:

$$r=\frac{\dfrac{d_{\text{net}}}{\frac{1}{2}v}}{\dfrac{d_{\text{concrete}}}{\frac{1}{2}v}}=\frac{d_{\text{net}}}{d_{\text{concrete}}}$$

Assuming that the net gives about 1 m and concrete about 0.1 mm yields:

$$r=\frac{1\,\text{m}}{0.1\,\text{mm}}\approx\boxed{10^{4}}$$

16 •• (*a*) Why does a drinking glass survive a fall onto a carpet but not onto a concrete floor? (*b*) On many race tracks, dangerous curves are surrounded by massive bails of hay. Explain how this setup reduces the chances of car damage and driver injury.

Determine the Concept In both (*a*) and (*b*), longer impulse times (Impulse = $F_{\text{av}}\Delta t$) are the result of collisions with a carpet and bails of hay. The average force on a drinking glass or a car is reduced (nothing can be done about the impulse, or change in linear momentum, during a collision but increasing the impulse time decreases the average force acting on an object) and the likelihood of breakage, damage or injury is reduced.

17 • True or false:

(*a*) Following any perfectly inelastic collision, the kinetic energy of the system is zero after the collision in all inertial reference frames.
(*b*) For a head-on elastic collision, the relative speed of recession equals the relative speed of approach.
(*c*) During a perfectly inelastic head-on collision with one object initially at rest, only some of the system's kinetic energy is dissipated.

(*d*) After a perfectly inelastic head-on collision along the east-west direction, the two objects are observed to be moving west. The initial total system momentum was, therefore, to the west.

(*a*) False. Following a perfectly inelastic collision, the colliding bodies stick together but may or may not continue moving, depending on the momentum each brings to the collision.

(*b*) True. For a head-on elastic collision both kinetic energy and momentum are conserved and the relative speeds of approach and recession are equal.

(*c*) True. This is the definition of an inelastic collision.

(*d*) True. The linear momentum of the system before the collision must be in the same direction as the linear momentum of the system after the collision.

18 •• Under what conditions can all the initial kinetic energy of an isolated system consisting of two colliding objects be lost in a collision? Explain how this result can be, and yet the momentum of the system can be conserved.

Determine the Concept If the collision is perfectly inelastic, the bodies stick together and neither will be moving after the collision. Therefore, the final kinetic energy will be zero and all of it will have been lost (that is, transformed into some other form of energy). Momentum is conserved because in an isolated system the net external force is zero.

19 •• Consider a perfectly inelastic collision of two objects of equal mass. (*a*) Is the loss of kinetic energy greater if the two objects are moving in opposite directions, each moving at speed $v/2$, or if one of the two objects is initially at rest and the other has an initial speed of v? (*b*) In which of these situations is the percentage loss in kinetic energy the greatest?

Determine the Concept We can find the loss of kinetic energy in these two collisions by finding the initial and final kinetic energies. We'll use conservation of momentum to find the final velocities of the two masses in each perfectly elastic collision.

(*a*) Letting V represent the velocity of the masses after their perfectly inelastic collision, use conservation of momentum to determine V:

$$p_{\text{before}} = p_{\text{after}}$$

or

$$mv - mv = 2mV \Rightarrow V = 0$$

Express the loss of kinetic energy for the case in which the two objects have oppositely directed velocities of magnitude $v/2$:

$$\Delta K = K_f - K_i = 0 - 2\left(\tfrac{1}{2}m\left(\frac{v}{2}\right)^2\right)$$
$$= -\tfrac{1}{4}mv^2$$

Letting V represent the velocity of the masses after their perfectly inelastic collision, use conservation of momentum to determine V:

$$p_{\text{before}} = p_{\text{after}}$$
or
$$mv = 2mV \Rightarrow V = \tfrac{1}{2}v$$

Express the loss of kinetic energy for the case in which the one object is initially at rest and the other has an initial velocity v:

$$\Delta K = K_f - K_i$$
$$= \tfrac{1}{2}(2m)\left(\frac{v}{2}\right)^2 - \tfrac{1}{2}mv^2 = -\tfrac{1}{4}mv^2$$

The loss of kinetic energy is the same in both cases.

(b) Express the percentage loss for the case in which the two objects have oppositely directed velocities of magnitude $v/2$:

$$\frac{\Delta K}{K_{\text{before}}} = \frac{\frac{1}{4}mv^2}{\frac{1}{4}mv^2} = 100\%$$

Express the percentage loss for the case in which the one object is initially at rest and the other has an initial velocity v:

$$\frac{\Delta K}{K_{\text{before}}} = \frac{\frac{1}{4}mv^2}{\frac{1}{2}mv^2} = 50\%$$

The percentage loss is greatest for the case in which the two objects have oppositely directed velocities of magnitude $v/2$.

20 •• A double-barreled pea shooter is shown in Figure 8-41. Air is blown into the left end of the pea shooter, and identical peas A and B are positioned inside each straw as shown. If the pea shooter is held horizontally while the peas are shot off, which pea, A or B, will travel farther after leaving the straw? Explain. Base your explanation on the impulse–momentum theorem.

Determine the Concept Pea A will travel farther. Both peas are acted on by the same force, but pea A is acted on by that force for a longer time. By the impulse-momentum theorem, its momentum (and, hence, speed) will be higher than pea B's speed on leaving the shooter.

21 •• A particle of mass m_1 traveling with a speed v makes a head-on elastic collision with a stationary particle of mass m_2. In which scenario will the largest amount of energy be imparted to the particle of mass m_2? (*a*) $m_2 < m_1$, (*b*) $m_2 = m_1$, (*c*) $m_2 > m_1$, (*d*) None of the above.

Determine the Concept Refer to the particles as particle 1 and particle 2. Let the direction particle 1 is moving before the collision be the positive x direction. We'll use both conservation of momentum and conservation of mechanical energy to obtain an expression for the velocity of particle 2 after the collision. Finally, we'll examine the ratio of the final kinetic energy of particle 2 to that of particle 1 to determine the condition under which there is maximum energy transfer from particle 1 to particle 2.

Use conservation of momentum to obtain one relation for the final velocities:

$$m_1 v_{1,\text{i}} = m_1 v_{1,\text{f}} + m_2 v_{2,\text{f}} \qquad (1)$$

Use conservation of mechanical energy to set the velocity of recession equal to the negative of the velocity of approach:

$$v_{2,\text{f}} - v_{1,\text{f}} = -\left(v_{2,\text{i}} - v_{1,\text{i}}\right) = v_{1,\text{i}} \qquad (2)$$

To eliminate $v_{1,\text{f}}$, solve equation (2) for $v_{1,\text{f}}$, and substitute the result in equation (1):

$$v_{1,\text{f}} = v_{2,\text{f}} + v_{1,\text{i}}$$

$$m_1 v_{1,\text{i}} = m_1\left(v_{2,\text{f}} - v_{1,\text{i}}\right) + m_2 v_{2,\text{f}}$$

Solve for $v_{2,\text{f}}$ to obtain:

$$v_{2,\text{f}} = \frac{2m_1}{m_1 + m_2} v_{1,\text{i}}$$

Express the ratio R of $K_{2,\text{f}}$ to $K_{1,\text{i}}$ in terms of m_1 and m_2:

$$R = \frac{K_{2,\text{f}}}{K_{1,\text{i}}} = \frac{\frac{1}{2} m_2 \left(\dfrac{2m_1}{m_1 + m_2}\right)^2 v_{1,\text{i}}^2}{\frac{1}{2} m_1 v_{1,\text{i}}^2}$$

$$= \frac{m_2}{m_1} \frac{4m_1^2}{\left(m_1 + m_2\right)^2}$$

Differentiate this ratio with respect to m_2, set the derivative equal to zero, and obtain the quadratic equation:

$$-\frac{m_2^2}{m_1^2} + 1 = 0$$

Solve this equation for m_2 to determine its value for maximum energy transfer:

$$m_2 = m_1$$

$\boxed{(b)}$ is correct because all of particle 1's kinetic energy is transferred to particle 2 when $m_2 = m_1$.

22 •• Suppose you are in charge of an accident-reconstruction team which has reconstructed an accident in which a car was ″rear-ended″ causing the two cars to lock bumpers and skid to a halt. During the trial, you are on the stand as an expert witness for the prosecution and the defense lawyer claims that you wrongly neglected friction and the force of gravity during the fraction of a second while the cars collided. Defend your report. Why were you correct in ignoring these forces? You did not ignore these two forces in your skid analysis both before and after the collision. Can you explain to the jury why you did not ignore these two forces during the pre- and post-collision skids?

Determine the Concept You only used conservation of linear momentum for a fraction of a second of actual contact between the cars. Over that short time, friction and other external forces can be neglected. In the long run, over the duration of the accident, they cannot.

23 •• Nozzles for a garden hose are often made with a right-angle shape as shown in Figure 8-42. If you open the nozzle and spray water out, you will find that the nozzle presses against your hand with a pretty strong force—much stronger than if you used a nozzle not bent into a right angle. Why is this situation true?

Determine the Concept The water is changing direction when it rounds the corner in the nozzle. Therefore, the nozzle must exert a force on the stream of water to change its momentum, and from Newton's third law, the water exerts an equal but opposite force on the nozzle. This requires a net force in the direction of the momentum change.

Conceptual Problems from Optional Sections

24 •• Describe a perfectly inelastic head-on collision between two stunt cars as viewed in the center-of-mass reference frame.

Determine the Concept In the center-of-mass reference frame the two objects approach with equal but opposite momenta and remain at rest after the collision.

25 •• One air-hockey puck is initially at rest. An identical air-hockey puck collides with it, striking it with a glancing blow. Assume the collision was elastic and neglect any rotational motion of the pucks. Describe the collision in the center-of-mass frame of the pucks.

Determine the Concept In the center-of-mass frame the two velocities are equal and opposite, both before and after the collision. In addition, the speed of each puck is the same before and after the collision. The direction of the velocity of each puck changes by some angle during the collision.

26 •• A baton with one end more massive than the other is tossed at an angle into the air. (*a*) Describe the trajectory of the center of mass of the baton in the reference frame of the ground. (*b*) Describe the motion of the two ends of the baton in the center-of-mass frame of the baton.

Determine the Concept
(*a*) In the center-of-mass frame of the ground, the center of mass moves in a parabolic arc.

(*b*) Relative to the center of mass, each end of the baton would describe a circular path. The more massive end of the baton would travel in the circle with the smaller radius because it is closer to the location of the center of mass.

27 •• Describe the forces acting on a descending Lunar lander as it fires its retrorockets to slow it down for a safe landing. (Assume the lander's mass loss during the rocket firing is not negligible.)

Determine the Concept The forces acting on a descending Lunar lander are the downward force of lunar gravity and the upward thrust provided by the rocket engines.

28 •• A railroad car rolling along by itself is passing by a grain elevator, which is dumping grain into it at a constant rate. (*a*) Does momentum conservation imply that the railroad car should be slowing down as it passes the grain elevator? Assume that the track is frictionless and perfectly level and that the grain is falling vertically. (*b*) If the car is slowing down, this situation implies that there is some external force acting on the car to slow it down. Where does this force come from? (*c*) After passing the elevator, the railroad car springs a leak, and grain starts leaking out of a vertical hole in its floor at a constant rate. Should the car speed up as it loses mass?

Determine the Concept We can apply conservation of linear momentum and Newton's laws of motion to each of these scenarios.

(*a*) Yes, the car should slow down. An easy way of seeing this is to imagine a "packet" of grain being dumped into the car all at once: This is a completely inelastic collision, with the packet having an initial horizontal velocity of 0. After

the collision, it is moving with the same horizontal velocity that the car does, so the car must slow down.

(*b*) When the packet of grain lands in the car, it initially has a horizontal velocity of 0, so it must be accelerated to come to the same speed as the car of the train. Therefore, the train must exert a force on it to accelerate it. By Newton's third law, the grain exerts an equal but opposite force on the car, slowing it down. In general, this is a frictional force which causes the grain to come to the same speed as the car.

(*c*) No it dos not speed up. Imagine a packet of grain being "dumped" out of the railroad car. This can be treated as a collision, too. It has the same horizontal speed as the railroad car when it leaks out, so the train car doesn't have to speed up or slow down to conserve momentum.

29 ••• [SSM] To show that even really intelligent people can make mistakes, consider the following problem which was asked of a freshman class at Caltech on an exam (paraphrased): *A sailboat is sitting in the water on a windless day. In order to make the boat move, a misguided sailor sets up a fan in the back of the boat to blow into the sails to make the boat move forward. Explain why the boat won't move.* The idea was that the net force of the wind pushing the sail forward would be counteracted by the force pushing the fan back (Newton's third law). However, as one of the students pointed out to his professor, the sailboat *could* in fact move forward. Why is that?

Determine the Concept Think of the sail facing the fan (like the sail on a square rigger might), and think of the stream of air molecules hitting the sail. Imagine that they bounce off the sail elastically−their net change in momentum is then roughly twice the change in momentum that they experienced going through the fan. Thus the change in momentum of the air is backward, so to conserve momentum of the air-fan-boat system, the change in momentum of the fan-boat system will be forward.

Estimation and Approximation

30 •• A 2000-kg car traveling at 90 km/h crashes into an immovable concrete wall. (*a*) Estimate the time of collision, assuming that the center of the car travels halfway to the wall with constant acceleration. (Use any plausible length for the car.) (*b*) Estimate the average force exerted by the wall on the car.

Picture the Problem We can estimate the time of collision from the average speed of the car and the distance traveled by the center of the car during the collision. We'll assume a car length of 6.0 m. We can calculate the average force exerted by the wall on the car from the car's change in momentum and its stopping time.

(*a*) Relate the stopping time to the assumption that the center of the car travels halfway to the wall with constant deceleration:

$$\Delta t=\frac{d_{\text{stopping}}}{v_{\text{av}}}=\frac{\frac{1}{2}\left(\frac{1}{2}L_{\text{car}}\right)}{v_{\text{av}}}=\frac{\frac{1}{4}L_{\text{car}}}{v_{\text{av}}}\quad(1)$$

Because a is constant, the average speed of the car is given by:

$$v_{\text{av}}=\frac{v_{\text{i}}+v_{\text{f}}}{2}$$

Substitute numerical values and evaluate v_{av}:

$$v_{\text{av}}=\frac{0+90\dfrac{\text{km}}{\text{h}}\times\dfrac{1\,\text{h}}{3600\,\text{s}}\times\dfrac{1000\,\text{m}}{\text{km}}}{2}$$
$$=12.5\,\text{m/s}$$

Substitute numerical values in equation (1) and evaluate Δt:

$$\Delta t=\frac{\frac{1}{4}(6.0\,\text{m})}{12.5\,\text{m/s}}=0.120\,\text{s}=\boxed{0.12\,\text{s}}$$

(*b*) Relate the average force exerted by the wall on the car to the car’s change in momentum:

$$F_{\text{av}}=\frac{\Delta p}{\Delta t}=\frac{(2000\,\text{kg})\left(90\dfrac{\text{km}}{\text{h}}\times\dfrac{1\,\text{h}}{3600\,\text{s}}\times\dfrac{1000\,\text{m}}{\text{km}}\right)}{0.120\,\text{s}}=\boxed{4.2\times10^{5}\,\text{N}}$$

31 •• In hand-pumped railcar races, a speed of 32.0 km/h has been achieved by teams of four people. A car that has a mass equal to 350 kg is moving at that speed toward a river when Carlos, the chief pumper, notices that the bridge ahead is out. All four people (each with a mass of 75.0 kg) simultaneously jump backward off the car with a velocity that has a horizontal component of 4.00 m/s relative to the car. The car proceeds off the bank and falls into the water a horizontal distance of 25.0 m from the bank. (*a*) Estimate the time of the fall of the railcar. (*b*) What is the horizontal component of the velocity of the pumpers when they hit the ground?

Picture the Problem Let the direction the railcar is moving be the +*x* direction and the system include Earth, the pumpers, and the railcar. We’ll also denote the railcar with the letter c and the pumpers with the letter p. We’ll use conservation of linear momentum to relate the center of mass frame velocities of the car and the pumpers and then transform to the Earth frame of reference to find the time of fall of the car.

(*a*) Relate the time of fall of the railcar to the horizontal distance it travels and its horizontal speed as it leaves the bank:

$$\Delta t = \frac{\Delta x}{v_c} \qquad (1)$$

Use conservation of momentum to find the speed of the car relative to the speed of its center of mass:

$$\vec{p}_i = \vec{p}_f$$

or

$$m_c u_c + m_p u_p = 0$$

Relate u_c to u_p and solve for u_c:

$$u_p - u_c = -4.00\text{ m/s}$$

and

$$u_p = u_c - 4.00\text{ m/s}$$

Substitute for u_p to obtain:

$$m_c u_c + m_p(u_c - 4.00\text{ m/s}) = 0$$

Solving for u_c yields:

$$u_c = \frac{4.00\text{ m/s}}{1 + \frac{m_c}{m_p}}$$

Substitute numerical values and evaluate u_c:

$$u_c = \frac{4.00\text{ m/s}}{1 + \frac{350\text{ kg}}{4(75.0\text{ kg})}} = 1.846\text{ m/s}$$

Relate the speed of the car to its speed relative to the center of mass of the system:

$$v_c = u_c + v_{cm}$$

Substitute numerical values and evaluate v_c:

$$v_c = 1.846\frac{\text{m}}{\text{s}} + \left(32.0\frac{\text{km}}{\text{h}}\right)\left(\frac{1\text{ h}}{3600\text{ s}}\right)\left(\frac{1000\text{ m}}{\text{km}}\right) = 10.73\text{ m/s}$$

Substitute numerical values in equation (1) and evaluate Δt:

$$\Delta t = \frac{25.0\text{ m}}{10.73\text{ m/s}} = \boxed{2.33\text{ s}}$$

(*b*) The horizontal velocity of the pumpers when they hit the ground is:

$$v_p = v_c - u_p = 10.73\text{ m/s} - 4.00\text{ m/s} = \boxed{6.7\text{ m/s}}$$

32 •• A wooden block and a gun are firmly fixed to opposite ends of a long glider mounted on a frictionless air track (Figure 8-43). The block and gun are a distance L apart. The system is initially at rest. The gun is fired and the bullet leaves the gun with a velocity v_b and impacts the block, becoming imbedded in it. The mass of the bullet is m_b and the mass of the gun–glider–block system is m_p. (*a*) What is the velocity of the glider immediately after the bullet leaves the gun? (*b*) What is the velocity of the glider immediately after the bullet comes to rest in the block? (*c*) How far does the glider move while the bullet is in transit between the gun and the block?

Picture the Problem Let the system include Earth, platform, gun, bullet, and block. Then $\vec{F}_{\text{net,ext}} = 0$ and momentum is conserved within the system. Choose a coordinate system in which the $+x$ direction is the direction of the bullet and let b and p denote the bullet and platform, respectively.

(*a*) Apply conservation of linear momentum to the system just before and just after the bullet leaves the gun:

$$\vec{p}_{\text{before}} = \vec{p}_{\text{after}}$$

or

$$0 = \vec{p}_{\text{bullet}} + \vec{p}_{\text{glider}}$$

Substitute for $\vec{p}_{\text{bullet}}$ and $\vec{p}_{\text{glider}}$ to obtain:

$$0 = m_b v_b \hat{\boldsymbol{i}} + m_p \vec{v}_p$$

Solving for $\vec{v}_p$ yields:

$$\vec{v}_p = \boxed{-\frac{m_b}{m_p} v_b \hat{\boldsymbol{i}}}$$

(*b*) Apply conservation of momentum to the system just before the bullet leaves the gun and just after it comes to rest in the block:

$$\vec{p}_{\text{before}} = \vec{p}_{\text{after}}$$

or

$$0 = \vec{p}_{\text{glider}} \Rightarrow \vec{v}_{\text{glider}} = \boxed{0}$$

(*c*) Express the distance Δs traveled by the glider:

$$\Delta s = v_p \Delta t$$

Express the velocity of the bullet relative to the glider:

$$v_{\text{rel}} = v_b - v_p = v_b + \frac{m_b}{m_p} v_b$$

$$= \left(1 + \frac{m_b}{m_p}\right) v_b = \frac{m_p + m_b}{m_p} v_b$$

Relate the time of flight Δt to L and v_{rel}:

$$\Delta t = \frac{L}{v_{rel}}$$

Substitute and simplify to find the distance Δs moved by the glider in time Δt:

$$\Delta s = v_p \Delta t = \left(\frac{m_b}{m_p} v_b\right)\left(\frac{L}{v_{rel}}\right) = \left(\frac{m_b}{m_p} v_b\right)\left(\frac{L}{\dfrac{m_p + m_b}{m_p} v_b}\right) = \boxed{\left(\frac{m_b}{m_p + m_b}\right)L}$$

Conservation of Linear Momentum

33 • **[SSM]** Tyrone, an 85-kg teenager, runs off the end of a horizontal pier and lands on a free-floating 150-kg raft that was initially at rest. After he lands on the raft, the raft, with him on it, moves away from the pier at 2.0 m/s. What was Tyrone's speed as he ran off the end of the pier?

Picture the Problem Let the system include Earth, the raft, and Tyrone and apply conservation of linear momentum to find Tyrone's speed when he ran off the end of the pier.

Apply conservation of linear momentum to the system consisting of the raft and Tyrone to obtain:

$$\Delta\vec{p}_{system} = \Delta\vec{p}_{Tyrone} + \Delta\vec{p}_{raft} = 0$$

or, because the motion is one-dimensional,

$$p_{f,Tyrone} - p_{i,\,Tyrone} + p_{f,raft} - p_{i,raft} = 0$$

Because the raft is initially at rest:

$$p_{f,Tyrone} - p_{i,\,Tyrone} + p_{f,raft} = 0$$

Use the definition of linear momentum to obtain:

$$m_{Tyrone} v_{f,Tyrone} - m_{Tyrone} v_{i,Tyrone} + m_{raft} v_{f,raft} = 0$$

Solve for $v_{i,Tyrone}$ to obtain:

$$v_{i,Tyrone} = \frac{m_{raft}}{m_{Tyrone}} v_{f,raft} + v_{f,Tyrone}$$

Letting v represent the common final speed of the raft and Tyrone yields:

$$v_{i,Tyrone} = \left(1 + \frac{m_{raft}}{m_{Tyrone}}\right)v$$

Substitute numerical values and evaluate $v_{\text{i,Tyrone}}$:

$$v_{\text{i, Tyrone}} = \left(1 + \frac{150\text{ kg}}{85\text{ kg}}\right)(2.0\text{ m/s}) = \boxed{5.5\text{ m/s}}$$

34 •• A 55-kg woman contestant on a reality television show is at rest at the south end of a horizontal 150-kg raft that is floating in crocodile-infested waters. She and the raft are initially at rest. She needs to jump from the raft to a platform that is several meters off the north end of the raft. She takes a running start. When she reaches the north end of the raft she is running at 5.0 m/s relative to the raft. At that instant, what is her velocity relative to the water?

Picture the Problem Let the system include the woman, the raft, and Earth. Then the *net* external force is zero and linear momentum is conserved as she jumps off the raft. Let the direction the woman is running be the +*x* direction.

Apply conservation of linear momentum to the system:

$$\sum m_i \vec{v}_i = m_{\text{woman}}\vec{v}_{\text{woman}} + m_{\text{raft}}\vec{v}_{\text{raft}} = 0$$

Solving for $\vec{v}_{\text{raft}}$ yields:

$$\vec{v}_{\text{raft}} = -\frac{m_{\text{woman}}\vec{v}_{\text{woman}}}{m_{\text{raft}}}$$

Substituting numerical values gives:

$$\vec{v}_{\text{raft}} = -\left(\frac{55\text{ kg}}{150\text{ kg}}\right)\vec{v}_{\text{woman}} = -\left(\frac{55}{150}\right)\vec{v}_{\text{woman}}$$

It is given that:

$$\vec{v}_{\text{woman}} - \vec{v}_{\text{raft}} = (5.0\text{ m/s})\hat{\boldsymbol{i}}$$

Substituting for $\vec{v}_{\text{raft}}$ yields:

$$\vec{v}_{\text{woman}} + \left(\frac{55}{150}\right)\vec{v}_{\text{woman}} = (5.0\text{ m/s})\hat{\boldsymbol{i}}$$

Solve for $\vec{v}_{\text{woman}}$ to obtain:

$$\vec{v}_{\text{woman}} = \left(\frac{5.0\text{ m/s}}{1 + \dfrac{55}{150}}\right)\hat{\boldsymbol{i}} = \boxed{(3.7\text{ m/s})\hat{\boldsymbol{i}}}$$

35 • A 5.0-kg object and a 10-kg object, both resting on a frictionless table, are connected by a massless compressed spring. The spring is released and the objects fly off in opposite directions. The 5.0-kg object has a velocity of 8.0 m/s to the left. What is the velocity of the 10-kg object?

Picture the Problem If we include Earth in our system, then the net external force is zero and linear momentum is conserved as the spring delivers its energy to the two objects. Choose a coordinate system in which the +*x* direction is to the right.

Apply conservation of linear momentum to the system:

$$\sum m_i\vec{v}_i = m_5\vec{v}_5 + m_{10}\vec{v}_{10} = 0$$

Solving for $\vec{v}_{10}$ yields:

$$\vec{v}_{10} = \left(-\frac{m_5}{m_{10}}\right)\vec{v}_5$$

Substitute numerical values and evaluate $\vec{v}_{10}$:

$$\vec{v}_{10} = \left[-\frac{(5.0\,\text{kg})(-8.0\,\text{m/s})}{10\,\text{kg}}\right]\hat{i}$$
$$= \boxed{(4.0\,\text{m/s})\hat{i}}$$

or 4.0 m/s to the right.

36 • Figure 8-44 shows the behavior of a projectile just after it has broken up into three pieces. What was the speed of the projectile the instant before it broke up? (*a*) v_3. (*b*) $v_3/3$. (*c*) $v_3/4$. (*d*) $4v_3$. (*e*) $(v_1 + v_2 + v_3)/4$.

Picture the Problem This is an explosion-like event in which linear momentum is conserved. Thus we can equate the initial and final momenta in the *x* direction and the initial and final momenta in the *y* direction. Choose a coordinate system in the +*x* direction is to the right and the +*y* direction is upward.

Equate the momenta in the *y* direction before and after the explosion:

$$\sum p_{y,i} = \sum p_{y,f} = mv_2 - 2mv_1$$
$$= m(2v_1) - 2mv_1 = 0$$

We can conclude that the momentum was entirely in the *x* direction before the particle exploded.

Equate the momenta in the *x* direction before and after the explosion:

$$\sum p_{x,i} = \sum p_{x,f}$$

or

$$4mv_{\text{projectile}} = mv_3$$

Solving for $v_{\text{projectile}}$ yields:

$v_{\text{projectile}} = \frac{1}{4}v_3$ and $\boxed{(c)}$ is correct.

37 • A shell of mass m and speed v explodes into two identical fragments. If the shell was moving horizontally with respect to Earth, and one of the fragments is subsequently moving vertically with speed v, find the velocity $\vec{v}'$ of the other fragment immediately following the explosion.

Picture the Problem Choose the direction the shell is moving just before the explosion to be the positive x direction and apply conservation of momentum.

Use conservation of momentum to relate the masses of the fragments to their velocities:

$$\vec{p}_{\text{i}} = \vec{p}_{\text{f}}$$

or

$$mv\hat{i} = \tfrac{1}{2}mv\hat{j} + \tfrac{1}{2}m\vec{v}' \Rightarrow \vec{v}' = \boxed{2v\hat{i} - v\hat{j}}$$

38 •• During this week's physics lab, the experimental setup consists of two gliders on a horizontal frictionless air track (see Figure 8-45). Each glider supports a strong magnet centered on top of it, and the magnets are oriented so they attract each other. The mass of glider 1 and its magnet is 0.100 kg and the mass of glider 2 and its magnet is 0.200 kg. You and your lab partners take the origin to be at the left end of the track and to center glider 1 at x_1 = 0.100 m and glider 2 at x_2 = 1.600 m. Glider 1 is 10.0 cm long, while glider 2 is 20.0 cm long and each glider has its center of mass at its geometric center. When the two are released from rest, they will move toward each other and stick. (*a*) Predict the position of the center of each glider when they first touch. (*b*) Predict the velocity the two gliders will continue to move with after they stick. Explain the reasoning behind this prediction for your lab partners.

Picture the Problem Because no external forces act on either glider, the center of mass of the two-glider system can't move. We can use the data concerning the masses and separation of the gliders initially to calculate its location and then apply the definition of the center of mass a second time to relate the positions x_1 and x_2 of the centers of the carts when they first touch. We can also use the separation of the centers of the gliders when they touch to obtain a second equation in x_1 and x_2 that we can solve simultaneously with the equation obtained from the location of the center of mass.

(*a*) The x coordinate of the center of mass of the 2-glider system is given by:

$$x_{\text{cm}} = \frac{m_1x_1 + m_2x_2}{m_1 + m_2}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{\text{cm}} = \frac{(0.100\,\text{kg})(0.100\,\text{m}) + (0.200\,\text{kg})(1.600\,\text{m})}{0.100\,\text{kg} + 0.200\,\text{kg}} = 1.10\,\text{m}$$

from the left end of the air track.

Because the location of the center of mass has not moved when two gliders first touch:

$$1.10\,\text{m} = \frac{m_1 X_1 + m_2 X_2}{m_1 + m_2}$$

Substitute numerical values and simplify to obtain:

$$1.10\,\text{m} = \tfrac{1}{3} X_1 + \tfrac{2}{3} X_2$$

Also, when they first touch, their centers are separated by half their combined lengths:

$$X_2 - X_1 = \tfrac{1}{2}(10.0\,\text{cm} + 20.0\,\text{cm}) = 0.150\,\text{m}$$

Thus we have:

$$\tfrac{1}{3} X_1 + \tfrac{2}{3} X_2 = 1.10\,\text{m}$$

and

$$X_2 - X_1 = 0.150\,\text{m}$$

Solving these equations simultaneously yields:

$$X_1 = \boxed{1.00\,\text{m}} \text{ and } X_2 = \boxed{1.15\,\text{m}}$$

(*b*) Because the momentum of the system was zero initially, it must be zero just before the collision and after the collision in which the gliders stick together. Hence their velocity after the collision must be $\boxed{0}$.

39 •• Bored, a boy shoots his pellet gun at a piece of cheese that sits on a massive block of ice. On one particular shot, his 1.2 g pellet gets stuck in the cheese, causing it to slide 25 cm before coming to a stop. If the muzzle velocity of the gun is known to be 65 m/s, and the cheese has a mass of 120 g, what is the coefficient of friction between the cheese and ice?

Picture the Problem Let the system consist of the pellet and the cheese. Then we can apply the conservation of linear momentum and the conservation of energy with friction to this inelastic collision to find the coefficient of friction between the cheese and the ice.

Apply conservation of linear momentum to the system to obtain:

$$\Delta\vec{\boldsymbol{p}}_{\text{system}} = \Delta\vec{\boldsymbol{p}}_{\text{pellet}} + \Delta\vec{\boldsymbol{p}}_{\text{cheese}} = 0$$

or, because the motion is one-dimensional,

$$p_{\text{f,pellet}} - p_{\text{i,pellet}} + p_{\text{f,cheese}} - p_{\text{i,cheese}} = 0$$

Because the cheese is initially at rest:

$$p_{\text{f,pellet}} - p_{\text{i,pellet}} + p_{\text{f,cheeset}} = 0$$

Letting m represent the mass of the pellet, M the mass of the cheese, and v the common final speed of the pellet and the cheese, use the definition of linear momentum to obtain:

$$mv - mv_{\text{i,pellet}} + Mv = 0$$

Solving for v yields:

$$v = \frac{m}{m+M} v_{\text{i,pellet}} \qquad (1)$$

Apply the conservation of energy with friction to the system to obtain:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}}$$

or, because $W_{\text{ext}} = 0$,

$$\Delta K + \Delta U_{\text{g}} + \Delta E_{\text{therm}} = 0$$

Because $\Delta U_{\text{g}} = K_{\text{f}} = 0$, and $\Delta E_{\text{therm}} = f\Delta s$ (where Δs is the distance the cheese slides on the ice):

$$-\tfrac{1}{2}(m+M)v^2 + f\Delta s = 0$$

f is given by:

$$f = \mu_{\text{k}}(m+M)g$$

Substituting for f yields:

$$-\tfrac{1}{2}(m+M)v^2 + \mu_{\text{k}}(m+M)g\Delta s = 0$$

Substitute for v from equation (1) to obtain:

$$-\tfrac{1}{2}(m+M)\left(\frac{m}{m+M} v_{\text{i,pellet}}\right)^2 + \mu_{\text{k}}(m+M)g\Delta s = 0$$

Solving for μ_{k} yields:

$$\mu_{\text{k}} = \frac{1}{2g\Delta s}\left(\frac{mv_{\text{i,pellet}}}{m+M}\right)^2$$

Substitute numerical values and evaluate μ_{k}:

$$\mu_{\text{k}} = \frac{1}{2(9.81\ \text{m/s}^2)(0.25\ \text{m})}\left(\frac{(0.0012\ \text{kg})(65\ \text{m/s})}{0.0012\ \text{kg} + 0.120\ \text{kg}}\right)^2 = \boxed{0.084}$$

40 ••• A wedge of mass M, as shown in Figure 8-46, is placed on a frictionless, horizontal surface, and a block of mass m is placed on the wedge, whose surface is also frictionless. The center of mass of the block moves

downward a distance h, as the block slides from its initial position to the horizontal floor. (*a*) What are the speeds of the block and of the wedge, as they separate from each other and each go their own way? (*b*) Check your calculation plausibility by considering the limiting case when $M >> m$.

Picture the Problem Let the system include Earth, the block, and the wedge and apply conservation of energy and conservation of linear momentum.

(*a*) Apply conservation of energy with no frictional forces to the system to obtain:

$$W_{\text{ext}} = \Delta K + \Delta U$$

or, because $W_{\text{ext}} = 0$,

$$\Delta K + \Delta U = 0$$

Substituting for ΔK and ΔU yields:

$$K_{\text{f}} - K_{\text{i}} + U_{\text{f}} - U_{\text{i}} = 0$$

Because $K_{\text{i}} = U_{\text{f}} = 0$:

$$K_{\text{f}} - U_{\text{i}} = 0$$

Letting "b" refer to the block and "w" to the wedge yields:

$$K_{\text{b,f}} + K_{\text{w,f}} - U_{\text{b,i}} = 0$$

Substitute for $K_{\text{b,f}}$, $K_{\text{w,f}}$, and $U_{\text{b,i}}$ to obtain:

$$\tfrac{1}{2}mv_{\text{b}}^2 + \tfrac{1}{2}Mv_{\text{w}}^2 - mgh = 0 \qquad (1)$$

Applying conservation of linear momentum to the system yields:

$$\Delta\vec{\boldsymbol{p}}_{\text{sys}} = \Delta\vec{\boldsymbol{p}}_{\text{b}} + \Delta\vec{\boldsymbol{p}}_{\text{w}} = 0$$

or

$$\vec{\boldsymbol{p}}_{\text{b,f}} - \vec{\boldsymbol{p}}_{\text{b,i}} + \vec{\boldsymbol{p}}_{\text{w,f}} - \vec{\boldsymbol{p}}_{\text{w,i}} = 0$$

Because $\vec{\boldsymbol{p}}_{\text{b,i}} = \vec{\boldsymbol{p}}_{\text{w,i}} = 0$:

$$\vec{\boldsymbol{p}}_{\text{b,f}} + \vec{\boldsymbol{p}}_{\text{w,f}} = 0$$

Substituting for $\vec{\boldsymbol{p}}_{\text{b,f}}$ and $\vec{\boldsymbol{p}}_{\text{w,f}}$ yields:

$$-mv_{\text{b}}\hat{\boldsymbol{i}} + Mv_{\text{w}}\hat{\boldsymbol{i}} = 0$$

or

$$-mv_{\text{b}} + Mv_{\text{w}} = 0$$

Solve for v_{w} to obtain:

$$v_{\text{w}} = \frac{m}{M}v_{\text{b}} \qquad (2)$$

Substituting for v_{w} in equation (1) yields:

$$\tfrac{1}{2}mv_{\text{b}}^2 + \tfrac{1}{2}M\left(\frac{m}{M}v_{\text{b}}\right)^2 - mgh = 0$$

Solve for v_{b} to obtain:

$$v_{\text{b}} = \boxed{\sqrt{\frac{2ghM}{M+m}}} \qquad (3)$$

Substitute for v_b in equation (2) and simplify to obtain:

$$v_w = \frac{m}{M}\sqrt{\frac{2ghM}{M+m}} = \boxed{\sqrt{\frac{2ghm^2}{M(M+m)}}} \quad (4)$$

(*b*) Rewriting equation (3) by dividing the numerator and denominator of the radicand by *M* yields:

$$v_b = \sqrt{\frac{2gh}{1+\frac{m}{M}}}$$

When $M >> m$:

$$v_b = \sqrt{2gh}$$

Rewriting equation (4) by dividing the numerator and denominator of the radicand by *M* yields:

$$v_w = \sqrt{\frac{2gh\left(\frac{m}{M}\right)^2}{1+\frac{m}{M}}}$$

When $M >> m$:

$$v_w = 0$$

These results are exactly what we would expect in this case: The physics is that of a block sliding down a fixed wedge incline with no movement of the incline.

Kinetic Energy of a System of Particles

41 •• [SSM] A 3.0-kg block is traveling to the right (the +*x* direction) at 5.0 m/s, and a second 3.0-kg block is traveling to the left at 2.0 m/s. (*a*) Find the total kinetic energy of the two blocks. (*b*) Find the velocity of the center of mass of the two-block system. (*c*) Find the velocity of each block relative to the center of mass. (*d*) Find the kinetic energy of the blocks relative to the center of mass. (*e*) Show that your answer for Part (*a*) is greater than your answer for Part (*d*) by an amount equal to the kinetic energy associated with the motion of the center of mass.

Picture the Problem Choose a coordinate system in which the +*x* direction is to the right. Use the expression for the total momentum of a system to find the velocity of the center of mass and the definition of relative velocity to express the sum of the kinetic energies relative to the center of mass.

(*a*) The total kinetic energy is the sum of the kinetic energies of the blocks:

$$K = K_1 + K_2 = \tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2$$

Substitute numerical values and evaluate K:

$$K = \tfrac{1}{2}(3.0\,\text{kg})(5.0\,\text{m/s})^2 + \tfrac{1}{2}(3.0\,\text{kg})(2.0\,\text{m/s})^2 = 43.5\,\text{J} = \boxed{44\,\text{J}}$$

(*b*) Relate the velocity of the center of mass of the system to its total momentum:

$$M\vec{\boldsymbol{v}}_{\text{cm}} = m_1\vec{\boldsymbol{v}}_1 + m_2\vec{\boldsymbol{v}}_2$$

Solving for $\vec{v}_{\text{cm}}$ yields:

$$\vec{\boldsymbol{v}}_{\text{cm}} = \frac{m_1\vec{\boldsymbol{v}}_1 + m_2\vec{\boldsymbol{v}}_2}{m_1 + m_2}$$

Substitute numerical values and evaluate $\vec{\boldsymbol{v}}_{\text{cm}}$:

$$\vec{\boldsymbol{v}}_{\text{cm}} = \frac{(3.0\,\text{kg})(5.0\,\text{m/s})\hat{\boldsymbol{i}} + (3.0\,\text{kg})(-2.0\,\text{m/s})\hat{\boldsymbol{i}}}{3.0\,\text{kg} + 3.0\,\text{kg}} = \boxed{(1.5\,\text{m/s})\hat{\boldsymbol{i}}}$$

(*c*) The velocity of an object relative to the center of mass is given by:

$$\vec{\boldsymbol{v}}_{\text{rel}} = \vec{\boldsymbol{v}} - \vec{\boldsymbol{v}}_{\text{cm}}$$

Substitute numerical values to obtain:

$$\vec{\boldsymbol{v}}_{1,\text{rel}} = (5.0\,\text{m/s})\hat{\boldsymbol{i}} - (1.5\,\text{m/s})\hat{\boldsymbol{i}} = \boxed{(3.5\,\text{m/s})\hat{\boldsymbol{i}}}$$

$$\vec{\boldsymbol{v}}_{2,\text{rel}} = (-2.0\,\text{m/s})\hat{\boldsymbol{i}} - (1.5\,\text{m/s})\hat{\boldsymbol{i}} = \boxed{(-3.5\,\text{m/s})\hat{\boldsymbol{i}}}$$

(*d*) Express the sum of the kinetic energies relative to the center of mass:

$$K_{\text{rel}} = K_{1,\text{rel}} + K_{2,\text{rel}} = \tfrac{1}{2}m_1v_{1,\text{rel}}^2 + \tfrac{1}{2}m_2v_{2,\text{rel}}^2$$

Substitute numerical values and evaluate K_{rel}:

$$K_{\text{rel}} = \tfrac{1}{2}(3.0\,\text{kg})(3.5\,\text{m/s})^2 + \tfrac{1}{2}(3.0\,\text{kg})(-3.5\,\text{m/s})^2 = \boxed{37\,\text{J}}$$

(*e*) K_{cm} is given by:

$$K_{\text{cm}} = \tfrac{1}{2}m_{\text{tot}}v_{\text{cm}}^2$$

Substitute numerical values and evaluate K_{cm}:

$$K_{cm} = \tfrac{1}{2}(6.0\,\text{kg})(1.5\,\text{m/s})^2 = 6.75\,\text{J} = 43.5\,\text{J} - 36.75\,\text{J} = \boxed{K - K_{rel}}$$

42 •• Repeat Problem 41 with the second 3.0-kg block replaced by a 5.0-kg block moving to the right at 3.0 m/s.

Picture the Problem Choose a coordinate system in which the +*x* direction is to the right. Use the expression for the total momentum of a system to find the velocity of the center of mass and the definition of relative velocity to express the sum of the kinetic energies relative to the center of mass.

(*a*) The total kinetic energy is the sum of the kinetic energies of the blocks:

$$K = K_1 + K_2 = \tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2$$

Substitute numerical values and evaluate *K*:

$$K = \tfrac{1}{2}(3.0\,\text{kg})(5.0\,\text{m/s})^2 + \tfrac{1}{2}(5.0\,\text{kg})(3.0\,\text{m/s})^2 = 60.0\,\text{J} = \boxed{60\,\text{J}}$$

(*b*) Relate the velocity of the center of mass of the system to its total momentum:

$$M\vec{\boldsymbol{v}}_{cm} = m_1\vec{\boldsymbol{v}}_1 + m_2\vec{\boldsymbol{v}}_2$$

Solving for $\vec{\boldsymbol{v}}_{cm}$ yields:

$$\vec{\boldsymbol{v}}_{cm} = \frac{m_1\vec{\boldsymbol{v}}_1 + m_2\vec{\boldsymbol{v}}_2}{m_1 + m_2}$$

Substitute numerical values and evaluate $\vec{\boldsymbol{v}}_{cm}$:

$$\vec{\boldsymbol{v}}_{cm} = \frac{(3.0\,\text{kg})(5.0\,\text{m/s})\hat{\boldsymbol{i}} + (5.0\,\text{kg})(3.0\,\text{m/s})\hat{\boldsymbol{i}}}{3.0\,\text{kg} + 5.0\,\text{kg}} = (3.75\,\text{m/s})\hat{\boldsymbol{i}} = \boxed{(3.8\,\text{m/s})\hat{\boldsymbol{i}}}$$

(*c*) The velocity of an object relative to the center of mass is given by:

$$\vec{\boldsymbol{v}}_{rel} = \vec{\boldsymbol{v}} - \vec{\boldsymbol{v}}_{cm}$$

Substitute numerical values to obtain:

$$\vec{v}_{1,\text{rel}} = (5.0\,\text{m/s})\hat{i} - (3.75\,\text{m/s})\hat{i} = \boxed{(1.3\,\text{m/s})\hat{i}}$$

$$\vec{v}_{2,\text{rel}} = (3.0\,\text{m/s})\hat{i} - (3.75\,\text{m/s})\hat{i} = (-0.75\,\text{m/s})\hat{i} = \boxed{(-0.8\,\text{m/s})\hat{i}}$$

(*d*) Express the sum of the kinetic energies relative to the center of mass:

$$K_{\text{rel}} = K_{1,\text{rel}} + K_{2,\text{rel}} = \tfrac{1}{2}m_1v_{1,\text{rel}}^2 + \tfrac{1}{2}m_2v_{2,\text{rel}}^2$$

Substitute numerical values and evaluate K_{rel}:

$$K_{\text{rel}} = \tfrac{1}{2}(3.0\,\text{kg})(1.25\,\text{m/s})^2 + \tfrac{1}{2}(5.0\,\text{kg})(-0.75\,\text{m/s})^2 = 3.75\text{ J} = \boxed{4\,\text{J}}$$

(*e*) K_{cm} is given by:

$$K_{\text{cm}} = \tfrac{1}{2}m_{\text{tot}}v_{\text{cm}}^2$$

Substitute numerical values and evaluate K_{cm}:

$$K_{\text{cm}} = \tfrac{1}{2}(8.0\,\text{kg})(3.75\,\text{m/s})^2 \approx 56.3\,\text{J} \approx \boxed{K - K_{\text{rel}}}$$

Impulse and Average Force

43 • [SSM] You kick a soccer ball whose mass is 0.43 kg. The ball leaves your foot with an initial speed of 25 m/s. (*a*) What is the magnitude of the impulse associated with the force of your foot on the ball? (*b*) If your foot is in contact with the ball for 8.0 ms, what is the magnitude of the average force exerted by your foot on the ball?

Picture the Problem The impulse imparted to the ball by the kicker equals the *change* in the ball's momentum. The impulse is also the product of the average force exerted on the ball by the kicker and the time during which the average force acts.

(*a*) Relate the magnitude of the impulse delivered to the ball to its change in momentum:

$$I = |\Delta\vec{p}| = p_{\text{f}} - p_{\text{i}}$$

or, because $v_{\text{i}} = 0$,

$$I = mv_{\text{f}}$$

Substitute numerical values and evaluate *I*:

$$I = (0.43\,\text{kg})(25\,\text{m/s}) = 10.8\,\text{N}\cdot\text{s} = \boxed{11\,\text{N}\cdot\text{s}}$$

(*b*) The impulse delivered to the ball as a function of the average force acting on it is given by:

$$I = F_{av}\Delta t \Rightarrow F_{av} = \frac{I}{\Delta t}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = \frac{10.8\,\text{N}\cdot\text{s}}{0.0080\,\text{s}} = \boxed{1.3\,\text{kN}}$$

44 • A 0.30-kg brick is dropped from a height of 8.0 m. It hits the ground and comes to rest. (*a*) What is the impulse exerted by the ground on the brick during the collision? (*b*) If it takes 0.0013 s from the time the brick first touches the ground until it comes to rest, what is the average force exerted by the ground on the brick during impact?

Picture the Problem The impulse exerted by the ground on the brick equals the *change* in momentum of the brick and is also the product of the average force exerted by the ground on the brick and the time during which the average force acts.

(*a*) Express the magnitude of the impulse exerted by the ground on the brick:

$$I = \left|\Delta p_{\text{brick}}\right| = \left|p_{\text{f,brick}} - p_{\text{i,brick}}\right|$$

Because $p_{\text{f,brick}} = 0$:

$$I = p_{\text{i,brick}} = m_{\text{brick}}v \qquad (1)$$

Use conservation of energy to determine the speed of the brick at impact:

$$\Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0$$

Because $U_f = K_i = 0$:

$$K_f - U_i = 0$$

and

$$\tfrac{1}{2}m_{\text{brick}}v^2 - m_{\text{brick}}gh = 0 \Rightarrow v = \sqrt{2gh}$$

Substitute in equation (1) to obtain:

$$I = m_{\text{brick}}\sqrt{2gh}$$

Substitute numerical values and evaluate *I*:

$$I = (0.30\,\text{kg})\sqrt{2(9.81\,\text{m/s}^2)(8.0\,\text{m})}$$
$$= 3.76\,\text{N}\cdot\text{s} = \boxed{3.8\,\text{N}\cdot\text{s}}$$

(*c*) The average force acting on the brick is:

$$F_{av} = \frac{I}{\Delta t}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = \frac{3.76\,\text{N}\cdot\text{s}}{0.0013\,\text{s}} = \boxed{2.9\,\text{kN}}$$

45 • A meteorite that has a mass equal to 30.8 tonne (1 tonne = 1000 kg) is exhibited in the American Museum of Natural History in New York City. Suppose that the kinetic energy of the meteorite as it hit the ground was 617 MJ. Find the magnitude of the impulse *I* experienced by the meteorite up to the time its kinetic energy was halved (which took about t = 3.0 s). Find also the average force *F* exerted on the meteorite during this time interval.

Picture the Problem The impulse exerted by the ground on the meteorite equals the *change* in momentum of the meteorite and is also the product of the average force exerted by the ground on the meteorite and the time during which the average force acts.

Express the magnitude of the impulse exerted by the ground on the meteorite:

$$I = \left|\Delta\vec{\boldsymbol{p}}_{\text{meteorite}}\right| = p_f - p_i$$

Relate the kinetic energy of the meteorite to its initial momentum and solve for its initial momentum:

$$K_i = \frac{p_i^2}{2m} \Rightarrow p_i = \sqrt{2mK_i}$$

Express the ratio of the initial and final kinetic energies of the meteorite:

$$\frac{K_i}{K_f} = \frac{\dfrac{p_i^2}{2m}}{\dfrac{p_f^2}{2\text{m}}} = \frac{p_i^2}{p_f^2} = 2 \Rightarrow p_f = \frac{p_i}{\sqrt{2}}$$

Substitute in our expression for *I* and simplify:

$$I = \frac{p_i}{\sqrt{2}} - p_i = p_i\left(\frac{1}{\sqrt{2}} - 1\right)$$

$$= \sqrt{2mK_i}\left(\frac{1}{\sqrt{2}} - 1\right)$$

Because our interest is in its magnitude, substitute numerical values and evaluate the absolute value of *I*:

$$I = \left|\sqrt{2\left(30.8\times10^3\text{ kg}\right)\left(617\times10^6\text{ J}\right)}\left(\frac{1}{\sqrt{2}} - 1\right)\right| = \boxed{1.81\,\text{MN}\cdot\text{s}}$$

The average force acting on the meteorite is:

$$F_{av} = \frac{I}{\Delta t}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = \frac{1.81\,\text{MN}\cdot\text{s}}{3.0\,\text{s}} = \boxed{0.60\,\text{MN}}$$

46 •• A 0.15-kg baseball traveling horizontally is hit by a bat and its direction exactly reversed. Its velocity changes from +20 m/s to –20 m/s. (*a*) What is the magnitude of the impulse delivered by the bat to the ball? (*b*) If the baseball is in contact with the bat for 1.3 ms, what is the average force exerted by the bat on the ball?

Picture the Problem The impulse exerted by the bat on the ball equals the *change* in momentum of the ball and is also the product of the average force exerted by the bat on the ball and the time during which the bat and ball were in contact.

(*a*) Express the impulse exerted by the bat on the ball in terms of the change in momentum of the ball:

$$\vec{I} = \Delta\vec{p}_{\text{ball}} = \vec{p}_{\text{f}} - \vec{p}_{\text{i}} = mv_{\text{f}}\hat{i} - \left(-mv_{\text{i}}\hat{i}\right) = 2mv\,\hat{i}$$

where $v = v_{\text{f}} = v_{\text{i}}$

Substitute for m and v and evaluate $|\vec{I}|$:

$$I = 2(0.15\,\text{kg})(20\,\text{m/s}) = 6.00\,\text{N}\cdot\text{s} = \boxed{6.0\,\text{N}\cdot\text{s}}$$

(*b*) The average force acting on the ball is:

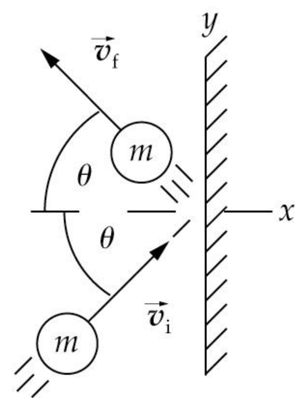
$$F_{av} = \frac{I}{\Delta t}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = \frac{6.00\,\text{N}\cdot\text{s}}{1.3\,\text{ms}} = \boxed{4.6\,\text{kN}}$$

47 •• A 60-g handball moving with a speed of 5.0 m/s strikes the wall at an angle of 40° with the normal, and then bounces off with the same speed at the same angle with the normal. It is in contact with the wall for 2.0 ms. What is the average force exerted by the ball on the wall?

Picture the Problem The figure shows the handball just before and immediately after its collision with the wall. Choose a coordinate system in which the +*x* direction is to the right. The wall changes the momentum of the ball by exerting a force on it during the ball's collision with it. The reaction to this force is the force the ball exerts on the wall. Because these action and reaction forces are equal in magnitude, we can find the average force exerted on the ball by finding the change in momentum of the ball.



Using Newton's 3rd law, relate the average force exerted by the ball on the wall to the average force exerted by the wall on the ball:

$$\vec{F}_{\text{av on wall}} = -\vec{F}_{\text{av on ball}}$$
and
$$F_{\text{av on wall}} = F_{\text{av on ball}} \quad (1)$$

Relate the average force exerted by the wall on the ball to its change in momentum:

$$\vec{F}_{\text{av on ball}} = \frac{\Delta\vec{p}}{\Delta t} = \frac{m\Delta\vec{v}}{\Delta t}$$

Express $\Delta\vec{v}$ in terms of its components:

$$\Delta\vec{v} = \Delta\vec{v}_x + \Delta\vec{v}_y$$
or, because $\Delta\vec{v}_y = v_{\text{f},y}\hat{j} - v_{\text{i},y}\hat{j}$ and $v_{\text{f},y} = v_{\text{i},y}$, $\Delta\vec{v} = \Delta\vec{v}_x$

Express $\Delta\vec{v}_x$ for the ball:

$$\Delta\vec{v}_x = v_{\text{f},x}\hat{i} - v_{\text{i},x}\hat{i}$$
or, because $v_{\text{i},x} = v\cos\theta$ and $v_{\text{f},x} = -v\cos\theta$,
$$\Delta\vec{v}_x = -v\cos\theta\,\hat{i} - v\cos\theta\,\hat{i} = -2v\cos\theta\,\hat{i}$$

Substituting in the expression for $\vec{F}_{\text{av on ball}}$ yields:

$$\vec{F}_{\text{av on ball}} = \frac{m\Delta\vec{v}}{\Delta t} = -\frac{2mv\cos\theta}{\Delta t}\hat{i}$$

The magnitude of $\vec{F}_{\text{av on ball}}$ is:

$$F_{\text{av on ball}} = \frac{2mv\cos\theta}{\Delta t}$$

Substitute numerical values and evaluate $F_{\text{av on ball}}$:

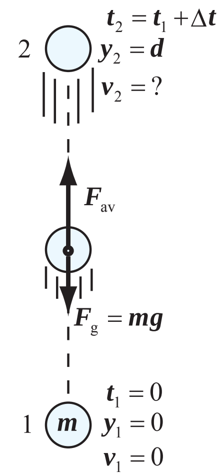
$$F_{\text{av on ball}} = \frac{2(0.060\,\text{kg})(5.0\,\text{m/s})\cos 40°}{2.0\,\text{ms}} = 0.23\,\text{kN}$$

Substitute in equation (1) to obtain:

$$F_{\text{av on wall}} = \boxed{0.23\,\text{kN}}$$

48 •• You throw a 150-g ball straight up to a height of 40.0 m. (*a*) Use a reasonable value for the displacement of the ball while it is in your hand to estimate the time the ball is in your hand while you are throwing it. (*b*) Calculate the average force exerted by your hand while you are throwing it. (Is it OK to neglect the gravitational force on the ball while it is being thrown?)

Picture the Problem The pictorial representation shows the ball during the interval of time during which you are exerting a force on it to accelerate it upward. The average force you exert can be determined from the change in momentum of the ball. The change in the velocity of the ball can be found by applying conservation of mechanical energy to the ball-Earth system once it has left your hand.



(*a*) Relate the time the ball is in your hand to its average speed while it is in your hand and the displacement of your hand:

$$\Delta t = \frac{\Delta y}{v_{\text{av, in your hand}}}$$

Letting $U_g = 0$ at the initial elevation of your hand, use conservation of mechanical energy to relate the initial kinetic energy of the ball to its potential energy when it is at its highest point:

$$\Delta K + \Delta U = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_f *and* U_i and solve for v_2:

$$-\tfrac{1}{2}mv_2^2 + mgh = 0 \Rightarrow v_2 = \sqrt{2gh}$$

Because $v_{\text{av, in your hand}} = \tfrac{1}{2}v_2$:

$$\Delta t = \frac{\Delta y}{\tfrac{1}{2}v_2} = \frac{2\Delta y}{\sqrt{2gh}}$$

Assuming the displacement of your hand is 0.70 m as you throw the ball straight up, substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2(0.70\text{ m})}{\sqrt{2(9.81\text{ m/s}^2)(40\text{ m})}} = 50.0\text{ ms}$$
$$= \boxed{50\text{ ms}}$$

(*b*) Relate the average force exerted by your hand on the ball to the change in momentum of the ball:

$$F_{\text{av}} = \frac{\Delta p}{\Delta t} = \frac{p_2 - p_1}{\Delta t}$$

or, because $v_1 = p_1 = 0$,

$$F_{\text{av}} = \frac{mv_2}{\Delta t}$$

Substitute for v_2 to obtain:

$$F_{\text{av}} = \frac{m\sqrt{2gh}}{\Delta t}$$

Substitute numerical values and evaluate F_{av}:

$$F_{\text{av}} = \frac{(0.15\text{ kg})\sqrt{2(9.81\text{ m/s}^2)(40\text{ m})}}{50.0\text{ ms}}$$
$$= 84.04\text{ N} = \boxed{84\text{ N}}$$

Express the ratio of the gravitational force on the ball to the average force acting on it:

$$\frac{F_{\text{g}}}{F_{\text{av}}} = \frac{mg}{F_{\text{av}}}$$

Substitute numerical values and evaluate $F_{\text{g}}/F_{\text{av}}$:

$$\frac{F_{\text{g}}}{F_{\text{av}}} = \frac{(0.15\text{ kg})(9.81\text{ m/s}^2)}{84.04\text{ N}} < 2\%$$

Because the gravitational force acting on the ball is less than 2% of the average force exerted by your hand on the ball, it is reasonable to have neglected the gravitational force.

49 •• A 0.060-kg handball is thrown straight toward a wall with a speed of 10 m/s. It rebounds straight backward at a speed of 8.0 m/s. (*a*) What impulse is exerted on the wall? (*b*) If the ball is in contact with the wall for 3.0 ms, what average force is exerted on the wall by the ball? (*c*) The rebounding ball is caught by a player who brings it to rest. During the process, her hand moves back 0.50 m. What is the impulse received by the player? (*d*) What average force was exerted on the player by the ball?

Picture the Problem Choose a coordinate system in which the direction the ball is moving *after* its collision with the wall is the +*x* direction. The impulse delivered to the wall or received by the player equals the change in the momentum of the ball during these two collisions. We can find the average forces from the rate of change in the momentum of the ball.

(*a*) The impulse delivered to the wall is the change in momentum of the handball:

$$\vec{I} = \Delta\vec{p} = m\vec{v}_f - m\vec{v}_i$$

Substitute numerical values and evaluate $\vec{I}$:

$$\begin{aligned}\vec{I} &= (0.060\,\text{kg})(8.0\,\text{m/s})\hat{i} \\ &\quad -\left[-(0.060\,\text{kg})(10\,\text{m/s})\hat{i}\right] \\ &= (1.08\,\text{N}\cdot\text{s})\hat{i} = \boxed{(1.1\,\text{N}\cdot\text{s})\hat{i}}\end{aligned}$$

or 1.1 N·s directed into the wall.

(*b*) F_{av} is the rate of change of the ball's momentum:

$$F_{av} = \frac{\Delta p}{\Delta t}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = \frac{1.08\,\text{N}\cdot\text{s}}{0.0030\,\text{s}} = 360\,\text{N}$$
$$= \boxed{0.36\,\text{kN, into the wall.}}$$

(*c*) The impulse received by the player from the change in momentum of the ball is given by:

$$I = \Delta p_{ball} = m\Delta v$$

Substitute numerical values and evaluate I:

$$I = (0.060\,\text{kg})(8.0\,\text{m/s}) = 0.480\,\text{N}\cdot\text{s}$$
$$= \boxed{0.48\,\text{N}\cdot\text{s, away from the wall.}}$$

(*d*) Relate F_{av} to the change in the ball's momentum:

$$F_{av} = \frac{\Delta p_{ball}}{\Delta t}$$

Express the stopping time in terms of the average speed v_{av} of the ball and its stopping distance d:

$$\Delta t = \frac{d}{v_{av}}$$

Substitute for Δt and simplify to obtain:

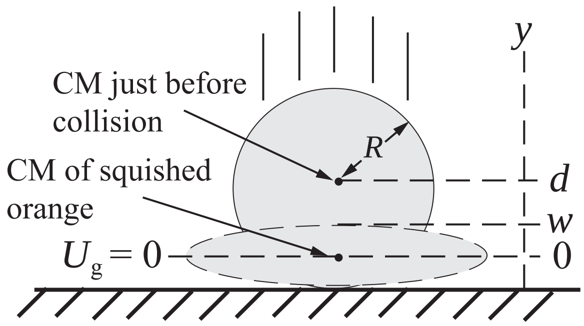
$$F_{av} = \frac{v_{av}\Delta p_{ball}}{d}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = \frac{(4.0\,\text{m/s})(0.480\,\text{N}\cdot\text{s})}{0.50\,\text{m}}$$
$$= \boxed{3.8\,\text{N, away from the wall.}}$$

50 •• A spherical 0.34-kg orange, 2.0 cm in radius, is dropped from the top of a 35 m-tall building. After striking the pavement, the shape of the orange is a 0.50 cm thick pancake. Neglect air resistance and assume that the collision is completely inelastic. (*a*) How much time did the orange take to completely "squish" to a stop? (*b*) What average force did the pavement exert on the orange during the collision?

Picture the Problem The following pictorial representation shows the orange moving with speed *v*, just before impact, after falling from a height of 35 m. Let the system be the orange and let the zero of gravitational potential energy be at the center of mass of the squished orange. The external forces are gravity, acting on the orange throughout its fall, and the normal force exerted by the ground that acts on the orange as it is squished. We can find the squishing time from the displacement of the center-of-mass of the orange as it stops and its average speed during this period of (assumed) constant acceleration. We can use the impulse-momentum theorem to find the average force exerted by the ground on the orange as it slowed to a stop.



(*a*) Express the stopping time for the orange in terms of its average speed and the distance traveled by its center of mass:

$$\Delta t = \frac{d}{v_{av}} = \frac{R - \frac{1}{2}w}{v_{av}} \quad (1)$$

where *w* is the thickness of the pancaked orange.

In order to find v_{av}, apply the conservation of mechanical energy to the free-fall portion of the orange's motion:

$$K_f - K_i + U_{g,f} - U_{g,i} = 0$$

or, because $K_i = 0$,

$$K_f + U_{g,f} - U_{g,i} = 0$$

Substituting for K_f, $U_{g,f}$, and $U_{g,i}$ yields:

$$\tfrac{1}{2}mv^2 + mgd - mg(h-d) = 0$$

Solving for *v* yields:

$$v = \sqrt{2gh\left(1 - 2\frac{d}{h}\right)}$$

or, because $d \ll h$,

$$v \approx \sqrt{2gh}$$

Assuming constant acceleration as the orange squishes:

$$v_{av}=\tfrac{1}{2}v=\tfrac{1}{2}\sqrt{2gh}$$

Substituting for v_{av} in equation (1) and simplifying yields:

$$\Delta t=\frac{2\left(R-\frac{1}{2}w\right)}{\sqrt{2gh}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t=\frac{2\left[2.0\text{ cm}-\frac{1}{2}(0.50\text{ cm})\right]}{\sqrt{2\left(9.81\text{ m/s}^2\right)(35\text{ m})}}=1.336\times10^{-3}\text{ s}=\boxed{1.3\text{ ms}}$$

(*b*) Apply the impulse-momentum theorem to the squishing orange to obtain:

$$\left|\vec{\boldsymbol{F}}_{av}\Delta \boldsymbol{t}\right|=\left|\Delta\vec{\boldsymbol{p}}\right|=\left|\vec{\boldsymbol{p}}_f-\vec{\boldsymbol{p}}_i\right|$$

or, because $p_f = 0$,

$$F_{av}\Delta t=p_i\Rightarrow F_{av}=\frac{p_i}{\Delta t}=\frac{mv_i}{\Delta t}$$

In Part (*a*) we showed that $v_i=v\approx\sqrt{2gh}$. Therefore:

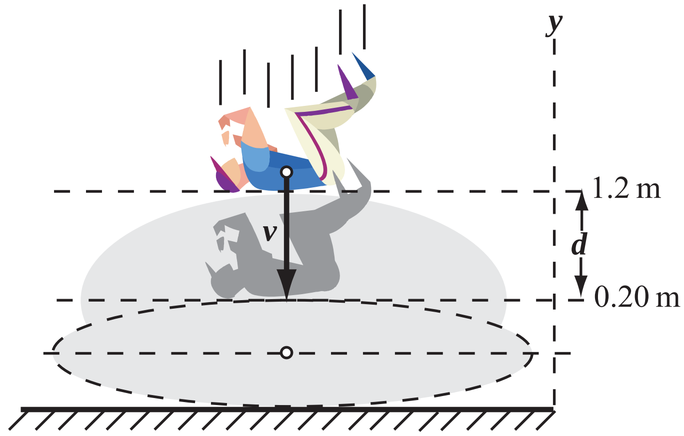
$$F_{av}=\frac{m\sqrt{2gh}}{\Delta t}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av}=\frac{(0.34\text{ kg})\sqrt{2\left(9.81\text{ m/s}^2\right)(35\text{ m})}}{1.336\times10^{-3}\text{ s}}\approx\boxed{6.7\text{ kN}}$$

51 •• The pole-vault landing pad at an Olympic competition contains what is essentially a bag of air that compresses from its "resting" height of 1.2 m down to 0.20 m as the vaulter is slowed to a stop. (*a*) What is the time interval during which a vaulter who has just cleared a height of 6.40 m slows to a stop? (*b*) What is the time interval if instead the vaulter is brought to rest by a 20 cm layer of sawdust that compresses to 5.0 cm when he lands? (*c*) Qualitatively discuss the difference in the average force the vaulter experiences from the two different landing pads. That is, which landing pad exerts the least force on the vaulter and why?

Picture the Problem The pictorial representation shows the vaulter just before impact on the landing pad after falling from a height of 6.40 m. In order to determine the time interval during which the vaulter stops, we have to know his momentum change and the average net force acting on him. With knowledge of these quantities, we can use the impulse-momentum equation, $F_{net}\Delta t=\Delta p$. We can determine the average force by noting that as the vaulter comes to a stop on the landing pad, work is done on him by the airbag.



(*a*) Use the impulse-momentum theorem to relate the stopping time to the average force acting on the vaulter:

$$F_{\text{net}}\Delta t = \Delta p$$

Use the work-kinetic energy theorem to obtain:

$$W_{\text{net}} = F_{\text{net}}d = \left(F_{\text{airbag}} - mg\right)d = \Delta K$$

where d is the distance the vaulter moves while being decelerated.

Substituting for F_{net} in equation (1) yields:

$$\left(F_{\text{airbag}} - mg\right)\Delta t = \Delta p$$

or

$$\frac{\Delta K}{d}\Delta t = \Delta p$$

Solve for Δt to obtain:

$$\Delta t = \frac{d\Delta p}{\Delta K} = \frac{d\left(p_{\text{f}} - p_{\text{i}}\right)}{K_{\text{f}} - K_{\text{i}}}$$

or, because $K_{\text{f}} = p_{\text{f}} = 0$,

$$\Delta t = \frac{d\left(-p_{\text{i}}\right)}{-K_{\text{i}}} = \frac{p_{\text{i}}d}{K_{\text{i}}}$$

Use $K = \dfrac{p^2}{2m}$ to obtain:

$$\Delta t = \frac{2mp_{\text{i}}d}{p_{\text{i}}^2} = \frac{2md}{p_{\text{i}}} = \frac{2md}{\sqrt{2mK_{\text{i}}}}$$

Rationalizing the denominator of this expression and simplifying yields:

$$\Delta t = d\sqrt{\frac{2m}{K_{\text{i}}}} \qquad (1)$$

K_i is equal to the change in the gravitational potential energy of the vaulter as he falls a distance Δy before hitting the airbag:

$$K_i = mg\Delta y$$

Substituting for K_i in equation (1) and simplifying yields:

$$\Delta t = d\sqrt{\frac{2}{g\Delta y}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = (1.2\text{ m} - 0.2\text{ m})\sqrt{\frac{2}{(9.81\text{ m/s}^2)(6.4\text{ m} - 1.2\text{ m})}} = 0.198\text{ s} = \boxed{0.20\text{ s}}$$

(*b*) In this case, d_1 = 20 cm, d_2 = 5.0 cm. Substitute numerical values and evaluate Δt:

$$\Delta t = (0.20\text{ m} - 0.05\text{ m})\sqrt{\frac{2}{(9.81\text{ m/s}^2)(6.4\text{ m} - 0.20\text{ m})}} = 27.2\text{ ms} = \boxed{27\text{ ms}}$$

(*c*) Because the collision time is much shorter for the sawdust landing, the average force exerted on the vaulter by the airbag is much less than the average force the sawdust exerts on him.

52 ••• Great limestone caverns have been formed by dripping water. (*a*) If water droplets of 0.030 mL fall from a height of 5.0 m at a rate of 10 droplets per minute, what is the average force exerted on the limestone floor by the droplets of water during a 1.0-min period? (Assume the water does not accumulate on the floor.) (*b*) Compare this force to the weight of one water droplet.

Picture the Problem The average force exerted on the limestone by the droplets of water equals the rate at which momentum is being delivered to the floor. We're given the number of droplets that arrive per minute and can use conservation of mechanical energy to determine their velocity as they reach the floor.

(*a*) Letting N represent the number of droplets that fall in a time interval Δt, relate F_{av} to the change in the droplet's momentum:

$$F_{av} = \frac{\Delta p_{\text{droplets}}}{\Delta t} = \frac{N}{\Delta t}mv \qquad (1)$$

where v is their speed after falling 5.0 m from rest.

The mass of the droplets is the product of their density and volume:

$$m = \rho V$$

Letting $U_g = 0$ at the point of impact of the droplets, use conservation of mechanical energy to relate their speed at impact to their fall distance:

$$\Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0$$

Because $K_i = U_f = 0$:

$$\tfrac{1}{2}mv^2 - mgh = 0 \Rightarrow v = \sqrt{2gh}$$

Substitute for m and v in equation (1) to obtain:

$$F_{av} = \frac{N}{\Delta t}\rho V\sqrt{2gh}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = 4.95\times10^{-5}\text{ N} = \boxed{50\ \mu\text{N}}$$

(*b*) Express the ratio of the weight of a droplet to F_{av}:

$$\frac{w}{F_{av}} = \frac{mg}{F_{av}}$$

Substitute numerical values and evaluate w/F_{av}:

$$\frac{w}{F_{av}} = \frac{(3\times10^{-5}\text{ kg})(9.81\text{m/s}^2)}{4.95\times10^{-5}\text{ N}} \approx \boxed{6}$$

Collisions in One Dimension

53 • [SSM] A 2000-kg car traveling to the right at 30 m/s is chasing a second car of the same mass that is traveling in the same direction at 10 m/s. (*a*) If the two cars collide and stick together, what is their speed just after the collision? (*b*) What fraction of the initial kinetic energy of the cars is lost during this collision? Where does it go?

Picture the Problem We can apply conservation of linear momentum to this perfectly inelastic collision to find the after-collision speed of the two cars. The ratio of the transformed kinetic energy to kinetic energy before the collision is the fraction of kinetic energy lost in the collision.

(*a*) Letting V be the velocity of the two cars after their collision, apply conservation of linear momentum to their perfectly inelastic collision:

$$p_{\text{initial}} = p_{\text{final}}$$

or

$$mv_1 + mv_2 = (m+m)V \Rightarrow V = \frac{v_1 + v_2}{2}$$

Substitute numerical values and evaluate V:

$$V=\frac{30\,\text{m/s}+10\,\text{m/s}}{2}=\boxed{20\,\text{m/s}}$$

(*b*) The ratio of the kinetic energy that is lost to the kinetic energy of the two cars before the collision is:

$$\frac{\Delta K}{K_{\text{initial}}}=\frac{K_{\text{final}}-K_{\text{initial}}}{K_{\text{initial}}}=\frac{K_{\text{final}}}{K_{\text{initial}}}-1$$

Substitute for the kinetic energies and simplify to obtain:

$$\frac{\Delta K}{K_{\text{initial}}}=\frac{\frac{1}{2}(2m)V^2}{\frac{1}{2}mv_1^2+\frac{1}{2}mv_2^2}-1$$
$$=\frac{2V^2}{v_1^2+v_2^2}-1$$

Substitute numerical values and evaluate $\Delta K/K_{\text{initial}}$:

$$\frac{\Delta K}{K_{\text{initial}}}=\frac{2(20\,\text{m/s})^2}{(30\,\text{m/s})^2+(10\,\text{m/s})^2}-1$$
$$=-0.20$$

Twenty percent of the initial kinetic energy is transformed into thermal energy, acoustical energy, and the deformation of the materials from which the car is constructed.

54 • An 85-kg running back moving at 7.0 m/s makes a perfectly inelastic head-on collision with a 105-kg linebacker who is initially at rest. What is the speed of the players just after their collision?

Picture the Problem We can apply conservation of linear momentum to this perfectly inelastic collision to find the after-collision speed of the two players.

Letting the subscript 1 refer to the running back and the subscript 2 refer to the linebacker, apply conservation of momentum to their perfectly inelastic collision:

$$p_{\text{i}}=p_{\text{f}}$$

or

$$m_1v_1=(m_1+m_2)V\Rightarrow V=\frac{m_1}{m_1+m_2}v_1$$

Substitute numerical values and evaluate V:

$$V=\frac{85\,\text{kg}}{85\,\text{kg}+105\,\text{kg}}(7.0\,\text{m/s})=\boxed{3.1\,\text{m/s}}$$

55 • A 5.0-kg object with a speed of 4.0 m/s collides head-on with a 10-kg object moving toward it with a speed of 3.0 m/s. The 10-kg object stops dead after the collision. (*a*) What is the post-collision speed of the 5.0-kg object? (*b*) Is the collision elastic?

Picture the Problem We can apply conservation of linear momentum to this collision to find the post-collision speed of the 5.0-kg object. Let the direction the 5.0-kg object is moving before the collision be the positive direction. We can decide whether the collision was elastic by examining the initial and final kinetic energies of the system.

(*a*) Letting the subscript 5 refer to the 5.0-kg object and the subscript 10 refer to the 10-kg object, apply conservation of momentum to obtain:

$$p_{\mathrm{i}} = p_{\mathrm{f}}$$

or

$$m_5 v_{\mathrm{i},5} - m_{10} v_{\mathrm{i},10} = m_5 v_{\mathrm{f},5}$$

Solve for $v_{\mathrm{f},5}$:

$$v_{\mathrm{f},5} = \frac{m_5 v_{\mathrm{i},5} - m_{10} v_{\mathrm{i},10}}{m_5}$$

Substitute numerical values and evaluate $v_{\mathrm{f},5}$:

$$v_{\mathrm{f},5} = \frac{(5.0\,\mathrm{kg})(4.0\,\mathrm{m/s}) - (10\,\mathrm{kg})(3.0\,\mathrm{m/s})}{5\,\mathrm{kg}} = \boxed{-2.0\,\mathrm{m/s}}$$

where the minus sign means that the 5.0-kg object is moving to the left after the collision.

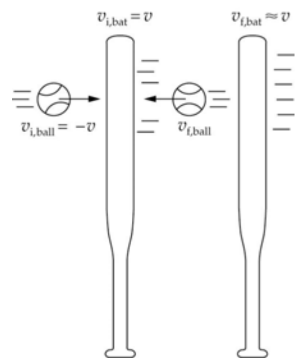
(*b*) Evaluate ΔK for the collision:

$$\Delta K = K_{\mathrm{f}} - K_{\mathrm{i}} = \tfrac{1}{2}(5.0\,\mathrm{kg})(2.0\,\mathrm{m/s})^2 - \left[\tfrac{1}{2}(5.0\,\mathrm{kg})(4.0\,\mathrm{m/s})^2 + \tfrac{1}{2}(10\,\mathrm{kg})(3.0\,\mathrm{m/s})^2\right]$$
$$= -75\,\mathrm{J}$$

Because $\Delta K \neq 0$, the collision was not elastic.

56 • A small superball of mass *m* moves with speed *v* to the right toward a much more massive bat that is moving to the left with speed *v*. Find the speed of the ball after it makes an elastic head-on collision with the bat.

Picture the Problem The pictorial representation shows the ball and bat just before and just after their collision. Take the direction the bat is moving to be the positive direction. Because the collision is elastic, we can equate the speeds of recession and approach, with the approximation that $v_{\text{i,bat}} \approx v_{\text{f,bat}}$ to find $v_{\text{f,ball}}$.



Express the speed of approach of the bat and ball:

$$v_{\text{f,bat}} - v_{\text{f,ball}} = -(v_{\text{i,bat}} - v_{\text{i,ball}})$$

Because the mass of the bat is much greater than that of the ball:

$$v_{\text{i,bat}} \approx v_{\text{f,bat}}$$

Substitute to obtain:

$$v_{\text{f,bat}} - v_{\text{f,ball}} = -(v_{\text{f,bat}} - v_{\text{i,ball}})$$

Solve for and evaluate $v_{\text{f,ball}}$:

$$\begin{aligned} v_{\text{f,ball}} &= v_{\text{f,bat}} + (v_{\text{f,bat}} - v_{\text{i,ball}}) \\ &= -v_{\text{i,ball}} + 2v_{\text{f,bat}} = v + 2v \\ &= \boxed{3v} \end{aligned}$$

57 •• A proton that has a mass m and is moving at 300 m/s undergoes a head-on elastic collision with a stationary carbon nucleus of mass $12m$. Find the velocity of the proton and the carbon nucleus after the collision.

Picture the Problem Let the direction the proton is moving before the collision be the $+x$ direction. We can use both conservation of momentum and conservation of mechanical energy to obtain an expression for velocities of the proton and the carbon nucleus after the collision.

Use conservation of linear momentum to obtain one relation for the final velocities:

$$m_{\text{p}} v_{\text{p,i}} = m_{\text{p}} v_{\text{p,f}} + m_{\text{nuc}} v_{\text{nuc,f}} \quad (1)$$

Use conservation of mechanical energy to set the velocity of recession equal to the negative of the velocity of approach:

$$v_{\text{nuc,f}} - v_{\text{p,f}} = -(v_{\text{nuc,i}} - v_{\text{p,i}}) = v_{\text{p,i}} \quad (2)$$

To eliminate $v_{nuc,f}$, solve equation (2) for $v_{nuc,f}$, and substitute the result in equation (1):

$$v_{nuc,f} = v_{p,i} + v_{p,f}$$

and

$$m_p v_{p,i} = m_p v_{p,f} + m_{nuc}(v_{p,i} + v_{p,f})$$

Solving for $v_{p,f}$ yields:

$$v_{p,f} = \frac{m_p - m_{nuc}}{m_p + m_{nuc}} v_{p,i}$$

Substituting for m_p and m_{nuc} and simplifying yields:

$$v_{p,f} = \frac{m - 12m}{m + 12m} v_{p,i} = -\frac{11}{13} v_{p,i}$$

Substitute the numerical value of $v_{p,i}$ and evaluate $v_{p,f}$:

$$v_{p,f} = -\frac{11}{13}(300\,\text{m/s}) = \boxed{-254\,\text{m/s}}$$

where the minus sign tells us that the velocity of the proton was reversed in the collision.

Solving equation (2) for $v_{nuc,f}$ yields:

$$v_{nuc,f} = v_{p,i} + v_{p,f}$$

Substitute numerical values and evaluate $v_{nuc,f}$:

$$v_{nuc,f} = 300\text{ m/s} - 254\text{ m/s} = \boxed{46\text{ m/s, forward}}$$

58 •• A 3.0-kg block moving at 4.0 m/s makes a head-on elastic collision with a stationary block of mass 2.0 kg. Use conservation of momentum and the fact that the relative speed of recession equals the relative speed of approach to find the velocity of each block after the collision. Check your answer by calculating the initial and final kinetic energies of each block.

Picture the Problem We can use conservation of momentum and the definition of an elastic collision to obtain two equations in v_{2f} and v_{3f} that we can solve simultaneously.

Use conservation of momentum to obtain one relation for the final velocities:

$$m_3 v_{3i} = m_3 v_{3f} + m_2 v_{2f} \quad (1)$$

Use conservation of mechanical energy to set the speed of recession equal to the negative of the speed of approach:

$$v_{2f} - v_{3f} = -(v_{2i} - v_{3i}) = v_{3i} \quad (2)$$

Solve equation (2) for v_{3f}, substitute in equation (1) to eliminate v_{3f}, and solve for v_{2f} to obtain:

$$v_{2f} = \frac{2m_3 v_{3i}}{m_2 + m_3}$$

Substitute numerical values and evaluate v_{2f}:

$$v_{2f} = \frac{2(3.0\,\text{kg})(4.0\,\text{m/s})}{2.0\,\text{kg} + 3.0\,\text{kg}} = 4.80\,\text{m/s}$$
$$= \boxed{4.8\,\text{m/s}}$$

Use equation (2) to find v_{3f}:

$$v_{3f} = v_{2f} - v_{3i} = 4.8\,\text{m/s} - 4.0\,\text{m/s}$$
$$= \boxed{0.8\,\text{m/s}}$$

Evaluate K_i and K_f:

$$K_i = K_{3i} = \tfrac{1}{2} m_3 v_{3i}^2 = \tfrac{1}{2}(3.0\,\text{kg})(4.0\,\text{m/s})^2 = 24\,\text{J}$$

and

$$K_f = K_{3f} + K_{2f} = \tfrac{1}{2} m_3 v_{3f}^2 + \tfrac{1}{2} m_2 v_{2f}^2$$
$$= \tfrac{1}{2}(3.0\,\text{kg})(0.8\,\text{m/s})^2 + \tfrac{1}{2}(2.0\,\text{kg})(4.8\,\text{m/s})^2 = 24\,\text{J}$$

Because $K_i = K_f$, we can conclude that the values obtained for v_{2f} and v_{3f} are consistent with the collision having been elastic.

59 •• A block of mass m_1 = 2.0 kg slides along a frictionless table with a speed of 10 m/s. Directly in front of it, and moving in the same direction with a speed of 3.0 m/s, is a block of mass m_2 = 5.0 kg. A massless spring that has a force constant k = 1120 N/m is attached to the second block as in Figure 8-47. (*a*) What is the velocity of the center of mass of the system? (*b*) During the collision, the spring is compressed by a maximum amount Δx. What is the value of Δx? (*c*) The blocks will eventually separate again. What are the final velocities of the two blocks measured in the reference frame of the table, after they separate?

Picture the Problem We can find the velocity of the center of mass from the definition of the total momentum of the system. We'll use conservation of energy to find the maximum compression of the spring and express the initial (i.e., before collision) and final (i.e., at separation) velocities. Finally, we'll transform the velocities from the center-of-mass frame of reference to the table frame of reference. Let the direction the block of mass m_1 is moving be the +x direction.

(*a*) Use the definition of the total momentum of a system to relate the initial momenta to the velocity of the center of mass:

$$\vec{P} = \sum_i m_i \vec{v}_i = M\vec{v}_{\text{cm}}$$

or

$$m_1\vec{v}_{1\text{i}} + m_2\vec{v}_{2\text{i}} = (m_1 + m_2)\vec{v}_{\text{cm}}$$

Solving for v_{cm} gives:

$$\vec{v}_{\text{cm}} = \frac{m_1}{m_1 + m_2}\vec{v}_{1\text{i}} + \frac{m_2}{m_1 + m_2}\vec{v}_{2\text{i}}$$

Substitute numerical values and evaluate $\vec{v}_{\text{cm}}$:

$$\vec{v}_{\text{cm}} = \left(\frac{2.0\text{ kg}}{2.0\text{ kg} + 5.0\text{ kg}}\right)(10\text{ m/s})\hat{i} + \left(\frac{3.0\text{ kg}}{2.0\text{ kg} + 5.0\text{ kg}}\right)(3.0\text{ m/s})\hat{i}$$
$$= (5.00\text{ m/s})\hat{i} = \boxed{(5.0\text{ m/s})\hat{i}}$$

(*b*) Find the kinetic energy of the system at maximum compression ($u_1 = u_2 = 0$):

$$K = K_{\text{cm}} = \tfrac{1}{2}Mv_{\text{cm}}^2$$
$$= \tfrac{1}{2}(7.0\text{ kg})(5.00\text{ m/s})^2 = 87.5\text{ J}$$

Use conservation of mechanical energy to relate the kinetic energy of the system to the potential energy stored in the spring at maximum compression:

$$\Delta K + \Delta U_{\text{s}} = 0$$

or

$$K_{\text{f}} - K_{\text{i}} + U_{\text{sf}} - U_{\text{si}} = 0$$

Because $K_{\text{f}} = K_{\text{cm}}$ and $U_{\text{si}} = 0$:

$$K_{\text{cm}} - K_{\text{i}} + \tfrac{1}{2}k(\Delta x)^2 = 0$$

Solving for Δx yields:

$$\Delta x = \sqrt{\frac{2(K_{\text{i}} - K_{\text{cm}})}{k}} = \sqrt{\frac{2\left[\frac{1}{2}m_1v_{1\text{i}}^2 + \frac{1}{2}m_2v_{2\text{i}}^2 - K_{\text{cm}}\right]}{k}} = \sqrt{\frac{m_1v_{1\text{i}}^2 + m_2v_{2\text{i}}^2 - 2K_{\text{cm}}}{k}}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \sqrt{\frac{(2.0\text{ kg})(10\text{ m/s})^2 + (5.0\text{ kg})(3.0\text{ m/s})^2}{1120\text{ N/m}} - \frac{2(87.5\text{ J})}{1120\text{ N/m}}\Bigg]} = \boxed{0.25\text{ m}}$$

(*c*) Find u_{1i}, u_{2i}, and u_{1f} for this elastic collision:

$$u_{1i} = v_{1i} - v_{cm} = 10\,\text{m/s} - 5\,\text{m/s} = 5\,\text{m/s},$$
$$u_{2i} = v_{2i} - v_{cm} = 3\,\text{m/s} - 5\,\text{m/s} = -2\,\text{m/s},$$
and
$$u_{1f} = v_{1f} - v_{cm} = 0 - 5\,\text{m/s} = -5\,\text{m/s}$$

Use conservation of mechanical energy to set the speed of recession equal to the negative of the speed of approach and solve for u_{2f}:

$$u_{2f} - u_{1f} = -(u_{2i} - u_{1i})$$
and
$$u_{2f} = -u_{2i} + u_{1i} + u_{1f}$$

Substitute numerical values and evaluate u_{2f}:

$$u_{2f} = -(-2.0\,\text{m/s}) + 5.0\,\text{m/s} - 5.0\,\text{m/s} = 2.0\,\text{m/s}$$

Transform u_{1f} and u_{2f} to the table frame of reference:

$$v_{1f} = u_{1f} + v_{cm} = -5.0\,\text{m/s} + 5.0\,\text{m/s} = 0$$
and
$$v_{2f} = u_{2f} + v_{cm} = 2.0\,\text{m/s} + 5.0\,\text{m/s} = 7.0\,\text{m/s}$$

Express the velocities of the blocks to obtain:

$$\vec{v}_{1f} = \boxed{0} \text{ and } \vec{v}_{2f} = \boxed{(7.0\,\text{m/s})\hat{i}}$$

60 •• A bullet of mass *m* is fired vertically from below into a thin horizontal sheet of plywood of mass *M* that is initially at rest, supported by a thin sheet of paper (Figure 8-48). The bullet punches through the plywood, which rises to a height *H* above the paper before falling back down. The bullet continues rising to a height *h* above the paper. (*a*) Express the upward velocity of the bullet and the plywood immediately after the bullet exits the plywood in terms of *h* and *H*. (*b*) What is the speed of the bullet? (*c*) What is the mechanical energy of the system before and after the inelastic collision? (*d*) How much mechanical energy is dissipated during the collision?

Picture the Problem Let the system include Earth, the bullet, and the sheet of plywood. Then $W_{ext} = 0$. Choose the zero of gravitational potential energy to be where the bullet enters the plywood. We can apply both conservation of energy and conservation of momentum to obtain the various physical quantities called for in this problem.

(*a*) Use conservation of mechanical energy after the bullet exits the sheet of plywood to relate its exit speed to the height to which it rises:

$$\Delta K + \Delta U = 0$$
or, because $K_f = U_i = 0$,
$$-\tfrac{1}{2}mv_m^2 + mgh = 0 \Rightarrow v_m = \boxed{\sqrt{2gh}}$$

Proceed similarly to relate the initial velocity of the plywood to the height to which it rises:

$$v_M = \boxed{\sqrt{2gH}}$$

(*b*) Apply conservation of momentum to the collision of the bullet and the sheet of plywood:

$$\vec{p}_i = \vec{p}_f$$

or

$$mv_{mi} = mv_m + Mv_M$$

Substitute for v_m and v_M and solve for v_{mi}:

$$v_{mi} = \boxed{\sqrt{2gh} + \frac{M}{m}\sqrt{2gH}}$$

(*c*) Express the initial mechanical energy of the system (i.e., just before the collision):

$$E_i = \tfrac{1}{2}mv_{mi}^2$$

$$= \boxed{mg\left[h + \frac{2M}{m}\sqrt{hH} + \left(\frac{M}{m}\right)^2 H\right]}$$

Express the final mechanical energy of the system (that is, when the bullet and block have reached their maximum heights):

$$E_f = mgh + MgH = \boxed{g(mh + MH)}$$

(*d*) Use the work-energy theorem with $W_{ext} = 0$ to find the energy dissipated by friction in the inelastic collision:

$$E_f - E_i + W_{friction} = 0$$

and

$$W_{friction} = E_i - E_f$$

$$= \boxed{gMH\left[2\sqrt{\frac{h}{H}} + \frac{M}{m} - 1\right]}$$

61 •• A proton of mass *m* is moving with initial speed v_0 directly toward the center of an α particle of mass 4*m*, which is initially at rest. Both particles carry positive charge, so they repel each other. (The repulsive forces are sufficient to prevent the two particles from coming into direct contact.) Find the speed v_α of the α particle (*a*) when the distance between the two particles is a minimum, and (*b*) later when the two particles are far apart.

Picture the Problem We can find the speed of the center of mass from the definition of the total momentum of the system. We'll use conservation of energy to find the speeds of the particles when their separation is a minimum and when they are far apart.

(*a*) Noting that when the distance between the two particles is a minimum, both move at the same speed, namely v_{cm}, use the definition of the total momentum of a system to relate the initial momenta to the speed of the center of mass:

$$\vec{P} = \sum_i m_i \vec{v}_i = M\vec{v}_{cm}$$

or

$$m_p v_p = (m_p + m_\alpha)v_{cm}\,.$$

Solve for v_{cm} to obtain:

$$v_{cm} = v_\alpha = \frac{m_p v_p + m_\alpha v_\alpha}{m_p + m_\alpha}$$

Further simplification yields:

$$v_{cm} = v_\alpha = \frac{mv_0 + 0}{m + 4m} = \boxed{0.2\,v_0}$$

(*b*) Use conservation of linear momentum to obtain one relation for the final speeds:

$$m_p v_0 = m_p v_{pf} + m_\alpha v_{\alpha f} \qquad (1)$$

Use conservation of mechanical energy to set the speed of recession equal to the negative of the speed of approach:

$$v_{pf} - v_{\alpha f} = -(v_{pi} - v_{\alpha i}) = -v_{pi} \qquad (2)$$

Solve equation (2) for v_{pf}, substitute in equation (1) to eliminate v_{pf}, and solve for $v_{\alpha f}$:

$$v_{\alpha f} = \frac{2m_p v_0}{m_p + m_\alpha}$$

Simplifying further yields:

$$v_{\alpha f} = \frac{2mv_0}{m + 4m} = \boxed{0.4\,v_0}$$

62 •• An electron collides elastically with a hydrogen atom initially at rest. Assume all the motion occurs along a straight line. What fraction of the electron's initial kinetic energy is transferred to the atom? (Take the mass of the hydrogen atom to be 1840 times the mass of an electron.)

Picture the Problem Let the numeral 1 denote the electron and the numeral 2 the hydrogen atom. We can find the final velocity of the electron and, hence, the fraction of its initial kinetic energy that is transferred to the atom, by transforming to the center-of-mass reference frame, calculating the post-collision velocity of the electron, and then transforming back to the laboratory frame of reference.

Express f, the fraction of the electron's initial kinetic energy that is transferred to the atom:

$$f = \frac{K_i - K_f}{K_i} = 1 - \frac{K_f}{K_i} = 1 - \frac{\frac{1}{2}m_1 v_{1f}^2}{\frac{1}{2}m_1 v_{1i}^2} = 1 - \left(\frac{v_{1f}}{v_{1i}}\right)^2 \quad (1)$$

Find the velocity of the center of mass:

$$v_{cm} = \frac{m_1 v_{1i}}{m_1 + m_2}$$

or, because $m_2 = 1840m_1$,

$$v_{cm} = \frac{m_1 v_{1i}}{m_1 + 1840m_1} = \frac{1}{1841}v_{1i}$$

Find the initial velocity of the electron in the center-of-mass reference frame:

$$u_{1i} = v_{1i} - v_{cm} = v_{1i} - \frac{1}{1841}v_{1i} = \left(1 - \frac{1}{1841}\right)v_{1i}$$

Find the post-collision velocity of the electron in the center-of-mass reference frame by reversing its velocity:

$$u_{1f} = -u_{1i} = \left(\frac{1}{1841} - 1\right)v_{1i}$$

To find the final velocity of the electron in the original frame, add v_{cm} to its final velocity in the center-of-mass reference frame:

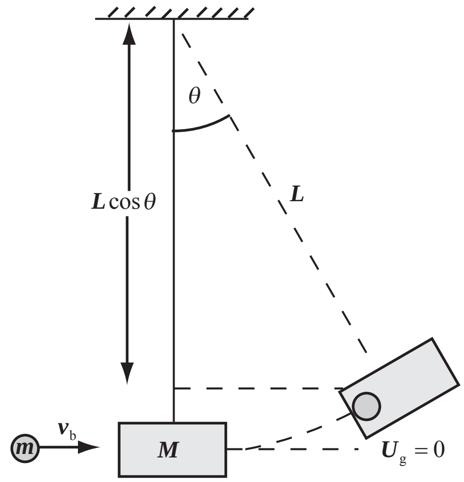
$$v_{1f} = u_{1f} + v_{cm} = \left(\frac{2}{1841} - 1\right)v_{1i}$$

Substituting in equation (1) and simplifying yields:

$$f = 1 - \left(\frac{2}{1841} - 1\right)^2 = \boxed{0.217\%}$$

63 •• [SSM] A16-g bullet is fired into the bob of a 1.5-kg ballistic pendulum (Figure 8-18). When the bob is at its maximum height, the strings make an angle of 60° with the vertical. The pendulum strings are 2.3 m long. Find the speed of the bullet prior to impact.

Picture the Problem The pictorial representation shows the bullet about to imbed itself in the bob of the ballistic pendulum and then, later, when the bob plus bullet have risen to their maximum height. We can use conservation of momentum during the collision to relate the speed of the bullet to the initial speed of the bob plus bullet (V). The initial kinetic energy of the bob plus bullet is transformed into gravitational potential energy when they reach their maximum height. Hence we apply conservation of mechanical energy to relate V to the angle through which the bullet plus bob swings and then solve the momentum and energy equations simultaneously for the speed of the bullet.



Use conservation of momentum to relate the speed of the bullet just before impact to the initial speed of the bob-bullet:

$$mv_b = (m+M)V \Rightarrow v_b = \left(1+\frac{M}{m}\right)V \quad (1)$$

Use conservation of energy to relate the initial kinetic energy of the bob-bullet to their final potential energy:

$$\Delta K + \Delta U = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f to obtain:

$$-\tfrac{1}{2}(m+M)V^2 + (m+M)gL(1-\cos\theta) = 0$$

Solving for V yields:

$$V = \sqrt{2gL(1-\cos\theta)}$$

Substitute for V in equation (1) to obtain:

$$v_b = \left(1+\frac{M}{m}\right)\sqrt{2gL(1-\cos\theta)}$$

Substitute numerical values and evaluate v_b:

$$v_b = \left(1+\frac{1.5\,\text{kg}}{0.016\,\text{kg}}\right)\sqrt{2(9.81\,\text{m/s}^2)(2.3\,\text{m})(1-\cos 60°)} = \boxed{0.45\,\text{km/s}}$$

64 •• Show that in a one-dimensional elastic collision, if the mass and velocity of object 1 are m_1 and v_{1i}, and if the mass and velocity of object 2 are m_2 and v_{2i}, then their final velocities v_{1f} and v_{2f} are given by

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2}v_{1i} + \frac{2m_2}{m_1 + m_2}v_{2i} \text{ and } v_{2f} = \frac{2m_1}{m_1 + m_2}v_{1i} + \frac{m_2 - m_1}{m_1 + m_2}v_{2i}.$$

Picture the Problem We can apply conservation of linear momentum and the definition of an elastic collision to obtain equations relating the initial and final velocities of the colliding objects that we can solve for v_{1f} and v_{2f}.

Apply conservation of momentum to the elastic collision of the particles to obtain:

$$m_1v_{1f} + m_2v_{2f} = m_1v_{1i} + m_2v_{2i} \quad (1)$$

Use conservation of mechanical energy to set the speed of recession equal to the negative of the speed of approach:

$$v_{2f} - v_{1f} = -(v_{2i} - v_{1i})$$

or

$$v_{1f} - v_{2f} = v_{2i} - v_{1i} \quad (2)$$

Multiply equation (2) by m_2 and add it to equation (1) to obtain:

$$(m_1 + m_2)v_{1f} = (m_1 - m_2)v_{1i} + 2m_2v_{2i}$$

Solve for v_{1f} to obtain:

$$v_{1f} = \boxed{\frac{m_1 - m_2}{m_1 + m_2}v_{1i} + \frac{2m_2}{m_1 + m_2}v_{2i}}$$

Multiply equation (2) by m_1 and subtract it from equation (1) to obtain:

$$(m_1 + m_2)v_{2f} = (m_2 - m_1)v_{2i} + 2m_1v_{1i}$$

Solve for v_{2f} to obtain:

$$v_{2f} = \boxed{\frac{2m_1}{m_1 + m_2}v_{1i} + \frac{m_2 - m_1}{m_1 + m_2}v_{2i}}$$

Remarks: Note that the velocities satisfy the condition that $\boldsymbol{v_{2f} - v_{1f} = -(v_{2i} - v_{1i})}$. This verifies that the speed of recession equals the speed of approach.

65 •• Investigate the plausibility of the results of Problem 64 by calculating the final velocities in the following limits: (*a*) When the two masses are equal, show that the particles "swap" velocities: $v_{1f} = v_{2i}$ i and $v_{2f} = v_{1i}$ (*b*) If $m_2 >> m_1$, and $v_{2i} = 0$, show that $v_{1f} \approx -v_{1i}$ and $v_{2f} \approx 0$. (*c*) If $m_1 >> m_2$, and $v_{2i} = 0$, show that $v_{1f} \approx v_{1i}$ and $v_{2f} \approx 2v_{1i}$.

Picture the Problem As in this problem, Problem 74 involves an elastic, one-dimensional collision between two objects. Both solutions involve using the conservation of momentum equation $m_1v_{1f} + m_2v_{2f} = m_1v_{1i} + m_2v_{2i}$ and the elastic collision equation $v_{1f} - v_{2f} = v_{2i} - v_{1i}$. In Part (*a*) we can simply set the masses equal to each other and substitute in the equations in Problem 64 to show that the particles "swap" velocities. In Part (*b*) we can divide the numerator and denominator of the equations in Problem 64 by m_2 and use the condition that $m_2 >> m_1$ to show that $v_{1f} \approx -v_{1i} + 2v_{2i}$ and $v_{2f} \approx v_{2i}$.

(*a*) From Problem 64 we have:

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2} v_{1i} + \frac{2m_2}{m_1 + m_2} v_{2i} \quad (1)$$

and

$$v_{2f} = \frac{2m_1}{m_1 + m_2} v_{1i} + \frac{m_2 - m_1}{m_1 + m_2} v_{2i} \quad (2)$$

Set $m_1 = m_2 = m$ to obtain:

$$v_{1f} = \frac{2m}{m+m} v_{2i} = \boxed{v_{2i}}$$

and

$$v_{2f} = \frac{2m}{m+m} v_{1i} = \boxed{v_{1i}}$$

(*b*) Divide the numerator and denominator of both terms in equation (1) by m_2 to obtain:

$$v_{1f} = \frac{\frac{m_1}{m_2} - 1}{\frac{m_1}{m_2} + 1} v_{1i} + \frac{2}{\frac{m_1}{m_2} + 1} v_{2i}$$

If $m_2 >> m_1$ and $v_{2i} = 0$:

$$v_{1f} \approx \boxed{-v_{1i}}$$

Divide the numerator and denominator of both terms in equation (2) by m_2 to obtain:

$$v_{2f} = \frac{2\frac{m_1}{m_2}}{\frac{m_1}{m_2} + 1} v_{1i} + \frac{1 - \frac{m_1}{m_2}}{\frac{m_1}{m_2} + 1} v_{2i}$$

If $m_2 >> m_1$:

$$v_{2f} \approx \boxed{v_{2i}}$$

(*c*) Divide the numerator and denominator of equation (1) by m_1 to obtain:

$$v_{1f} = \frac{1 - \frac{m_2}{m_1}}{1 + \frac{m_2}{m_1}} v_{1i} + \frac{2\frac{m_2}{m_1}}{1 + \frac{m_2}{m_1}} v_{2i}$$

If $m_1 >> m_2$ and $v_{2i} = 0$:

$$v_{1f} \approx \boxed{v_{1i}}$$

Divide the numerator and denominator of equation (2) by m_1 to obtain:

$$v_{2f} = \frac{2}{1 + \frac{m_2}{m_1}} v_{1i} + \frac{\frac{m_2}{m_1} - 1}{1 + \frac{m_2}{m_1}} v_{2i}$$

If $m_1 >> m_2$ and $v_{2i} = 0$:

$$v_{2f} \approx \boxed{2v_{1i}}$$

Remarks: Note that, in both parts of this problem, the velocities satisfy the condition that $v_{2f} - v_{1f} = -(v_{2i} - v_{1i})$. This verifies that the speed of recession equals the speed of approach.

66 •• A bullet of mass m_1 is fired horizontally with a speed v_0 into the bob of a ballistic pendulum of mass m_2. The pendulum consists of a bob attached to one end of a very light rod of length L. The rod is free to rotate about a horizontal axis through its other end. The bullet is stopped in the bob. Find the minimum v_0 such that the bob will swing through a complete circle.

Picture the Problem Choose $U_g = 0$ at the bob's equilibrium position. Momentum is conserved in the collision of the bullet with bob and the initial kinetic energy of the bob plus bullet is transformed into gravitational potential energy as it swings up to the top of the circle. If the bullet plus bob just makes it to the top of the circle with zero speed, it will swing through a complete circle.

Use conservation of momentum to relate the speed of the bullet just before impact to the initial speed of the bob plus bullet:

$$m_1 v_0 - (m_1 + m_2)V = 0$$

Solve for the speed of the bullet to obtain:

$$v_0 = \left(1 + \frac{m_2}{m_1}\right)V \qquad (1)$$

Use conservation of mechanical energy to relate the initial kinetic energy of the bob plus bullet to their potential energy at the top of the circle:

$$\Delta K + \Delta U = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f:

$$-\tfrac{1}{2}(m_1 + m_2)V^2 + (m_1 + m_2)g(2L) = 0$$

Solving for V yields:

$$V = 2\sqrt{gL}$$

Substitute for V in equation (1) and simplify to obtain:

$$v_0 = \boxed{2\left(1 + \frac{m_2}{m_1}\right)\sqrt{gL}}$$

67 •• A bullet of mass m_1 is fired horizontally with a speed v into the bob of a ballistic pendulum of mass m_2 (Figure 8-19). Find the maximum height h attained by the bob if the bullet passes through the bob and emerges with a speed $v/3$.

Picture the Problem Choose $U_g = 0$ at the equilibrium position of the ballistic pendulum. Momentum is conserved in the collision of the bullet with the bob and kinetic energy is transformed into gravitational potential energy as the bob swings up to its maximum height.

Letting V represent the initial speed of the bob as it begins its upward swing, use conservation of momentum to relate this speed to the speeds of the bullet just before and after its collision with the bob:

$$m_1 v = m_1\left(\tfrac{1}{3}v\right) + m_2 V \Rightarrow V = \frac{2m_1}{3m_2}v$$

Use conservation of energy to relate the initial kinetic energy of the bob to its potential energy at its maximum height:

$$\Delta K + \Delta U = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f:

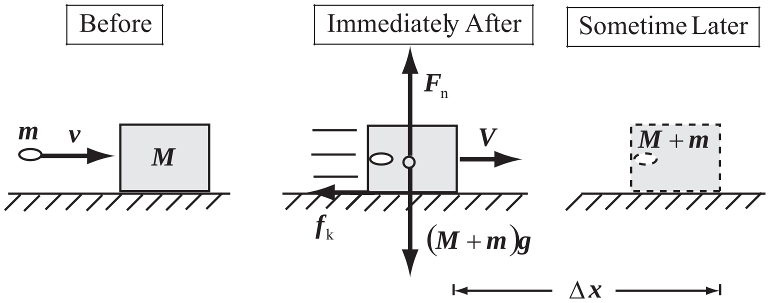
$$-\tfrac{1}{2}m_2 V^2 + m_2 g h = 0 \Rightarrow h = \frac{V^2}{2g}$$

Substitute for V in the expression for h and simplify to obtain:

$$h = \frac{\left(\dfrac{2m_1}{3m_2}v\right)^2}{2g} = \boxed{\frac{2m_1^2 v^2}{9m_2^2 g}}$$

68 •• A heavy wooden block rests on a flat table and a high-speed bullet is fired horizontally into the block, the bullet stopping in it. How far will the block slide before coming to a stop? The mass of the bullet is 10.5 g, the mass of the block is 10.5 kg, the bullet's impact speed is 750 m/s, and the coefficient of kinetic friction between the block and the table is 0.220. (Assume that the bullet does not cause the block to spin.)

Picture the Problem Let the mass of the bullet be m, that of the wooden block M, the pre-collision speed of the bullet v, and the post-collision speed of the block+bullet be V. We can use conservation of momentum to find the speed of the block with the bullet imbedded in it immediately after their perfectly inelastic collision. We can use Newton's second law to find the acceleration of the sliding block and a constant-acceleration equation to find the distance the block slides.



Using a constant-acceleration equation, relate the speed of the block+bullet just after their collision to their acceleration and displacement before stopping:

$$0 = V^2 + 2a\Delta x \Rightarrow \Delta x = -\frac{V^2}{2a}$$

because the final speed of the block+bullet is zero.

Use conservation of momentum to relate the pre-collision speed of the bullet to the post-collision speed of the block+bullet:

$$mv = (m+M)V \Rightarrow V = \frac{m}{m+M}v$$

Substitute for V in the expression for Δx to obtain:

$$\Delta x = -\frac{1}{2a}\left(\frac{m}{m+M}v\right)^2$$

Apply $\sum \vec{F} = m\vec{a}$ to the block+bullet (see the force diagram above):

$$\sum F_x = -f_k = (m+M)a \qquad (1)$$

and

$$\sum F_y = F_n - (m+M)g = 0 \qquad (2)$$

Use the definition of the coefficient of kinetic friction and equation (2) to obtain:

$$f_k = \mu_k F_n = \mu_k (m+M)g$$

Substituting for f_k in equation (1) yields:

$$-\mu_k(m+M)g = (m+M)a$$

Solve for a to obtain:

$$a = -\mu_k g$$

Substituting for a in the expression for Δx yields:

$$\Delta x = \frac{1}{2\mu_k g}\left(\frac{m}{m+M}v\right)^2$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{1}{2(0.220)(9.81\,\text{m/s}^2)}\left(\frac{0.0105\,\text{kg}}{0.0105\,\text{kg}+10.5\,\text{kg}}(750\,\text{m/s})\right)^2 = \boxed{13.0\,\text{cm}}$$

69 •• **[SSM]** A 0.425-kg ball with a speed of 1.30 m/s rolls across a level surface toward an open 0.327-kg box that is resting on its side. The ball enters the box, and the box (with the ball inside slides across the surface a distance of x = 0.520 m. What is the coefficient of kinetic friction between the box and the table?

Picture the Problem The collision of the ball with the box is perfectly inelastic and we can find the speed of the box-and-ball immediately after their collision by applying conservation of momentum. If we assume that the kinetic friction force is constant, we can use a constant-acceleration equation to find the acceleration of the box and ball combination and the definition of μ_k to find its value.

Using its definition, express the coefficient of kinetic friction of the table:

$$\mu_k = \frac{f_k}{F_n} = \frac{(M+m)|a|}{(M+m)g} = \frac{|a|}{g} \qquad (1)$$

Use conservation of momentum to relate the speed of the ball just before the collision to the speed of the ball+box immediately after the collision:

$$MV = (m+M)v \Rightarrow v = \frac{MV}{m+M} \qquad (2)$$

Use a constant-acceleration equation to relate the sliding distance of the ball+box to its initial and final velocities and its acceleration:

$$v_f^2 = v_i^2 + 2a\Delta x$$

or, because $v_f = 0$ and $v_i = v$,

$$0 = v^2 + 2a\Delta x \Rightarrow a = -\frac{v^2}{2\Delta x}$$

Substitute for a in equation (1) to obtain:

$$\mu_k = \frac{v^2}{2g\Delta x}$$

Use equation (2) to eliminate v:

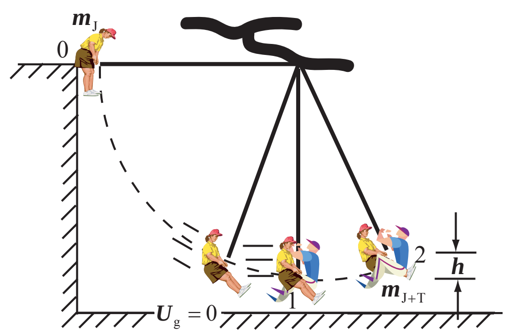
$$\mu_k = \frac{1}{2g\Delta x}\left(\frac{MV}{m+M}\right)^2 = \frac{1}{2g\Delta x}\left(\frac{V}{\frac{m}{M}+1}\right)^2$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{1}{2(9.81\,\text{m/s}^2)(0.520\,\text{m})}\left(\frac{1.30\,\text{m/s}}{\frac{0.327\,\text{kg}}{0.425\,\text{kg}}+1}\right)^2 = \boxed{0.0529}$$

70 •• Tarzan is in the path of a pack of stampeding elephants when Jane swings in to the rescue on a rope vine, hauling him off to safety. The length of the vine is 25 m, and Jane starts her swing with the rope horizontal. If Jane's mass is 54 kg, and Tarzan's is 82 kg, to what height above the ground will the pair swing after she rescues him? (Assume that the rope is vertical when she grabs him.)

Picture the Problem Jane's collision with Tarzan is a perfectly inelastic collision. We can find her speed v_1 just before she grabs Tarzan from conservation of energy and their speed V just after she grabs him from conservation of momentum. Their kinetic energy just after their collision will be transformed into gravitational potential energy when they have reached their greatest height h.



Use conservation of energy to relate the potential energy of Jane and Tarzan at their highest point (2) to their kinetic energy immediately after Jane grabbed Tarzan:

$$U_2 = K_1$$

or

$$m_{J+T}gh = \tfrac{1}{2}m_{J+T}V^2 \Rightarrow h = \frac{V^2}{2g} \qquad (1)$$

Apply conservation of linear momentum to relate Jane's velocity just before she collides with Tarzan to their velocity just after their perfectly inelastic collision:

$$m_J v_1 - m_{J+T}V = 0 \Rightarrow V = \frac{m_J}{m_{J+T}}v_1 \quad (2)$$

Apply conservation of mechanical energy to relate Jane's kinetic energy at 1 to her potential energy at 0:

$$K_1 = U_0$$

or

$$\tfrac{1}{2}m_J v_1^2 = m_J gL \Rightarrow v_1 = \sqrt{2gL}$$

Substitute for v_1 in equation (2) to obtain:

$$V = \frac{m_J}{m_{J+T}}\sqrt{2gL}$$

Substitute for V in equation (1) and simplify:

$$h = \frac{1}{2g}\left(\frac{m_J}{m_{J+T}}\right)^2 2gL = \left(\frac{m_J}{m_{J+T}}\right)^2 L$$

Substitute numerical values and evaluate h:

$$h = \left(\frac{54\,\text{kg}}{54\,\text{kg} + 82\,\text{kg}}\right)^2 (25\,\text{m}) = \boxed{3.9\,\text{m}}$$

71 •• [SSM] Scientists estimate that the meteorite responsible for the creation of Barringer Meteorite Crater in Arizona weighed roughly 2.72×10^5 tonne (1 tonne = 1000 kg) and was traveling at a speed of 17.9 km/s. Take Earth's orbital speed to be about 30.0 km/s. (*a*) What should the direction of impact be if Earth's orbital speed is to be changed by the maximum possible amount? (*b*) Assuming the condition of collision in Part (*a*), estimate the maximum percentage change in Earth's orbital speed as a result of this collision. (*c*) What mass asteroid, having a speed equal to Earth's orbital speed, would be necessary to change Earth's orbital speed by 1.00%?

Picture the Problem Let the system include Earth and the asteroid. Choose a coordinate system in which the direction of Earth's orbital speed is the +*x* direction. We can apply conservation of linear momentum to the perfectly inelastic collision of Earth and the asteroid to find the percentage change in Earth's orbital speed as well as the mass of an asteroid that would change Earth's orbital speed by 1.00%. Note that the following solution neglects the increase in Earth's orbital speed due to the gravitational pull of the asteroid during descent.

(*a*) The meteorite should impact Earth along a line exactly opposite Earth's orbital velocity vector.

(*b*) Express the percentage change in Earth's orbital speed as a result of the collision:

$$\left|\frac{\Delta v}{v_{\text{Earth}}}\right| = \left|\frac{v_{\text{Earth}} - v_{\text{f}}}{v_{\text{Earth}}}\right| = \left|1 - \frac{v_{\text{f}}}{v_{\text{Earth}}}\right| \qquad (1)$$

where v_{f} is Earth's orbital speed after the collision.

Apply the conservation of linear momentum to the system to obtain:

$$\Delta\vec{\boldsymbol{p}} = \vec{\boldsymbol{p}}_{\text{f}} - \vec{\boldsymbol{p}}_{\text{i}} = 0$$

or, because the asteroid and Earth are moving horizontally,

$$p_{\text{f},x} - p_{\text{i},x} = 0$$

Because the collision is perfectly inelastic:

$$(m_{\text{Earth}} + m_{\text{asteroid}})v_{\text{f}} - (m_{\text{Earth}}v_{\text{Earth}} - m_{\text{asteroid}}v_{\text{asteroid}}) = 0$$

Solving for v_f yields:

$$v_f = \frac{m_{\text{Earth}}v_{\text{Earth}} - m_{\text{asteroid}}v_{\text{asteroid}}}{m_{\text{Earth}} + m_{\text{asteroid}}} = \frac{m_{\text{Earth}}v_{\text{Earth}}}{m_{\text{Earth}} + m_{\text{asteroid}}} - \frac{m_{\text{asteroid}}v_{\text{asteroid}}}{m_{\text{Earth}} + m_{\text{asteroid}}}$$

$$= \frac{v_{\text{Earth}}}{1 + \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}} - \frac{\frac{m_{\text{asteroid}}}{m_{\text{Earth}}}v_{\text{asteroid}}}{1 + \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}}$$

Because $m_{\text{asteroid}} << m_{\text{Earth}}$:

$$v_f \approx v_{\text{Earth}} - \frac{\frac{m_{\text{asteroid}}}{m_{\text{Earth}}}v_{\text{asteroid}}}{1 + \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}} = v_{\text{Earth}} - \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}v_{\text{asteroid}}\left(1 + \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}\right)^{-1}$$

Expanding $\left(1 + \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}\right)^{-1}$ binomially yields:

$$\left(1 + \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}\right)^{-1} = 1 - \frac{m_{\text{asteroid}}}{m_{\text{Earth}}} + \text{higher order terms}$$

Substitute for $\left(1 + \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}\right)^{-1}$ in the expression for v_f to obtain:

$$v_f \approx v_{\text{Earth}} - \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}v_{\text{asteroid}}\left(1 - \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}\right)$$
$$\approx v_{\text{Earth}} - \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}v_{\text{asteroid}}$$

Substitute for v_f in equation (1) to obtain:

$$\left|\frac{\Delta v}{v_{\text{Earth}}}\right| = \left|1 - \frac{v_{\text{Earth}} - \frac{m_{\text{asteroid}}}{m_{\text{Earth}}}v_{\text{asteroid}}}{v_{\text{Earth}}}\right| = \left|\frac{\frac{m_{\text{asteroid}}}{m_{\text{Earth}}}v_{\text{asteroid}}}{v_{\text{Earth}}}\right|$$

Using data found in the appendices of your text or given in the problem statement, substitute numerical values and evaluate $\left|\frac{\Delta v}{v_{\text{Earth}}}\right|$:

$$\left|\frac{\Delta v}{v_{\text{Earth}}}\right| = \left|\frac{\dfrac{\left(2.72\times10^{5}\ \text{tonne}\times\dfrac{10^{3}\ \text{kg}}{1\ \text{tonne}}\right)(17.9\ \text{km/s})}{5.98\times10^{24}\ \text{kg}}}{30.0\ \text{km/s}}\right| = \boxed{2.71\times10^{-15}\%}$$

(*c*) If the asteroid is to change Earth's orbital speed by one percent:

$$\frac{\dfrac{m_{\text{asteroid}}}{m_{\text{Earth}}}v_{\text{asteroid}}}{v_{\text{Earth}}} = \frac{1}{100}$$

Solve for m_{asteroid} to obtain:

$$m_{\text{asteroid}} = \frac{v_{\text{Earth}}m_{\text{Earth}}}{100v_{\text{asteroid}}}$$

Substitute numerical values and evaluate m_{asteroid}:

$$m_{\text{asteroid}} = \frac{(30.0\ \text{km/s})(5.98\times10^{24}\ \text{kg})}{100(17.9\ \text{km/s})} = \boxed{1.00\times10^{23}\ \text{kg}}$$

Remarks: The mass of this asteroid is approximately that of the moon!

72 ••• William Tell shoots an apple from his son's head. The speed of the 125-g arrow just before it strikes the apple is 25.0 m/s, and at the time of impact it is traveling horizontally. If the arrow sticks in the apple and the arrow/apple combination strikes the ground 8.50 m behind the son's feet, how massive was the apple? Assume the son is 1.85 m tall.

Picture the Problem Let the system include Earth, the apple, and the arrow. Choose a coordinate system in which the direction the arrow is traveling before imbedding itself in the apple is the +*x* direction. We can apply conservation of linear momentum to express the mass of the apple in terms of the speed of the arrow-apple combination just after the collision and then use constant-acceleration equations to find this post-collision speed.

Apply conservation of linear momentum to the system to obtain:

$$\Delta\vec{\boldsymbol{p}} = \vec{\boldsymbol{p}}_\mathrm{f} - \vec{\boldsymbol{p}}_\mathrm{i} = 0$$

or, because the arrow and apple are moving horizontally,

$$p_{\mathrm{f},x} - p_{\mathrm{i},x} = 0$$

Because the collision is perfectly inelastic (the arrow is imbedded in the apple):

$$(m_\text{arrow} + m_\text{apple})v_x - m_\text{arrow}v_\text{i,arrow} = 0$$

Solving for m_apple yields:

$$m_\text{apple} = m_\text{arrow}\left(\frac{v_\text{i,arrow}}{v_x} - 1\right) \qquad (1)$$

Using constant-acceleration equations, express the horizontal and vertical displacements of the apple-arrow after their collision:

$$\Delta x = v_x \Delta t \qquad (2)$$

and

$$\Delta y = \tfrac{1}{2}g(\Delta t)^2 \Rightarrow \Delta t = \sqrt{\frac{2\Delta y}{g}}$$

Substituting for Δt in equation (2) yields:

$$\Delta x = v_x\sqrt{\frac{2\Delta y}{g}} \Rightarrow v_x = \Delta x\sqrt{\frac{g}{2\Delta y}}$$

Substitute for v_x in equation (1) to obtain:

$$m_\text{apple} = m_\text{arrow}\left(\frac{v_\text{i,arrow}}{\Delta x\sqrt{\dfrac{g}{2\Delta y}}} - 1\right)$$

Substitute numerical values and evaluate m_apple:

$$m_\text{apple} = (0.125\ \text{kg})\left(\frac{25.0\ \text{m/s}}{(8.50\ \text{m})\sqrt{\dfrac{9.81\ \text{m/s}^2}{2(1.85\ \text{m})}}} - 1\right) = \boxed{101\ \text{g}}$$

Explosions and Radioactive Decay

73 •• **[SSM]** The beryllium isotope ^{8}Be is unstable and decays into two α particles ($m_\alpha = 6.64 \times 10^{-27}$ kg) and releases 1.5×10^{-14} J of energy. Determine the velocities of the two α particles that arise from the decay of a ^{8}Be nucleus at rest, assuming that all the energy appears as kinetic energy of the particles.

Picture the Problem This nuclear reaction is $^{4}\text{Be} \rightarrow 2\alpha + 1.5 \times 10^{-14}$ J. In order to conserve momentum, the alpha particles will have move in opposite directions with the same velocities. We'll use conservation of energy to find their speeds.

Letting E represent the energy released in the reaction, express conservation of energy for this process:

$$2K_\alpha = 2\left(\tfrac{1}{2}m_\alpha v_\alpha^2\right) = E \Rightarrow v_\alpha = \sqrt{\frac{E}{m_\alpha}}$$

Substitute numerical values and evaluate v_α:

$$v_\alpha = \sqrt{\frac{1.5\times10^{-14}\ \text{J}}{6.64\times10^{-27}\ \text{kg}}} = \boxed{1.5\times10^{6}\ \text{m/s}}$$

74 •• The light isotope of lithium, ^{5}Li, is unstable and breaks up spontaneously into a proton and an α particle. During this process, 3.15×10^{-13} J of energy are released, appearing as the kinetic energy of the two decay products. Determine the velocities of the proton and the α particle that arise from the decay of a ^{5}Li nucleus at rest. (*Note*: The masses of the proton and alpha particle are $m_\text{p} = 1.67 \times 10^{-27}$ kg and $m_\alpha = 4m_\text{p} = 6.64 \times 10^{-27}$ kg.)

Picture the Problem This nuclear reaction is $^{5}\text{Li} \rightarrow \alpha + \text{p} + 3.15 \times 10^{-13}$ J. To conserve momentum, the alpha particle and proton must move in opposite directions. We'll apply both conservation of energy and conservation of momentum to find the speeds of the proton and alpha particle.

Use conservation of momentum in this process to express the alpha particle's speed in terms of the proton's:

$$p_\text{i} = p_\text{f} = 0$$

and

$$0 = m_\text{p}v_\text{p} - m_\alpha v_\alpha$$

Solve for v_α and substitute for m_α to obtain:

$$v_\alpha = \frac{m_\text{p}}{m_\alpha}v_\text{p} = \frac{m_\text{p}}{4m_\text{p}}v_\text{p} = \tfrac{1}{4}v_\text{p}$$

Letting E represent the energy released in the reaction, apply conservation of energy to the process:

$$K_\text{p} + K_\alpha = E$$

or

$$\tfrac{1}{2}m_\text{p}v_\text{p}^2 + \tfrac{1}{2}m_\alpha v_\alpha^2 = E$$

Substitute for v_α:

$$\tfrac{1}{2}m_\text{p}v_\text{p}^2 + \tfrac{1}{2}m_\alpha\left(\tfrac{1}{4}v_\text{p}\right)^2 = E$$

Solve for v_p and substitute for m_α to obtain:

$$v_\text{p} = \sqrt{\frac{32E}{16m_\text{p} + m_\alpha}}$$

Substitute numerical values and evaluate v_p:

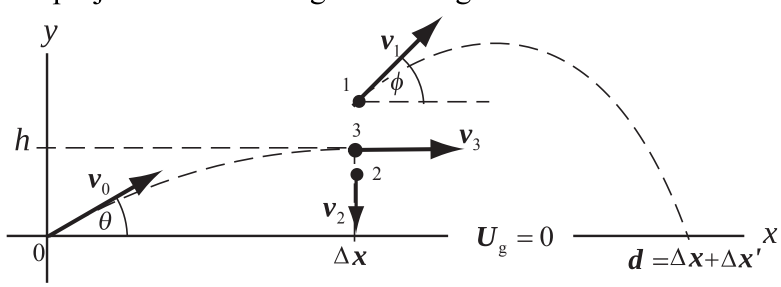
$$v_p = \sqrt{\frac{32(3.15\times10^{-13}\text{ J})}{16(1.67\times10^{-27}\text{ kg}) + 6.64\times10^{-27}\text{ kg}}} = \boxed{1.74\times10^{7}\text{ m/s}}$$

Use the relationship between v_p and v_α to obtain v_α:

$$v_\alpha = \tfrac{1}{4}v_p = \tfrac{1}{4}(1.74\times10^{7}\text{ m/s}) = \boxed{4.34\times10^{6}\text{ m/s}}$$

75 ••• A 3.00-kg projectile is fired with an initial speed of 120 m/s at an angle of 30.0º with the horizontal. At the top of its trajectory, the projectile explodes into two fragments of masses 1.00 kg and 2.00 kg. At 3.60 s after the explosion the 2.00-kg fragment lands on the ground directly below the point of explosion. (*a*) Determine the velocity of the 1.00-kg fragment immediately after the explosion. (*b*) Find the distance between the point of firing and the point at which the 1.00-kg fragment strikes the ground. (*c*) Determine the energy released in the explosion.

Picture the Problem The pictorial representation shows the projectile at its maximum elevation and is moving horizontally. It also shows the two fragments resulting from the explosion. We'll choose the system to include the projectile and Earth so that no external forces act to change the momentum of the system during the explosion. With this choice of system we can also use conservation of energy to determine the elevation of the projectile when it explodes. We'll also find it useful to use constant-acceleration equations in our description of the motion of the projectile and its fragments. Neglect air resistance.



(*a*) Use conservation of linear momentum to relate the velocity of the projectile before its explosion to the velocities of its two parts after the explosion:

$$\vec{p}_i = \vec{p}_f$$

$$m_3\vec{v}_3 = m_1\vec{v}_1 + m_2\vec{v}_2$$

$$m_3v_3\hat{i} = m_1v_{x1}\hat{i} + m_1v_{y1}\hat{j} - m_2v_{y2}\hat{j}$$

The only way this equality can hold is if the x and y components are equal:

$m_3 v_3 = m_1 v_{x1}$
and
$m_1 v_{y1} = m_2 v_{y2}$

Express v_3 in terms of v_0 and substitute for the masses to obtain:

$$v_{x1} = 3v_3 = 3v_0 \cos\theta = 3(120\text{ m/s})\cos 30.0° = 312\text{ m/s}$$
and
$$v_{y1} = 2v_{y2} \qquad (1)$$

Using a constant-acceleration equation with the downward direction positive, relate v_{y2} to the time it takes the 2.00-kg fragment to hit the ground:

$$h = v_{y2}\Delta t + \tfrac{1}{2}g(\Delta t)^2$$

Solving for v_{y2} gives:

$$v_{y2} = \frac{h - \frac{1}{2}g(\Delta t)^2}{\Delta t} \qquad (2)$$

With $U_g = 0$ at the launch site, apply conservation of energy to the climb of the projectile to its maximum elevation h:

$\Delta K + \Delta U = 0$
Because $K_f = U_i = 0$, $-K_i + U_f = 0$
or
$-\frac{1}{2}m_3 v_{y0}^2 + m_3 g h = 0$

Solving for h yields:

$$h = \frac{v_{y0}^2}{2g} = \frac{(v_0 \sin\theta)^2}{2g}$$

Substitute numerical values and evaluate h:

$$h = \frac{[(120\text{ m/s})\sin 30.0°]^2}{2(9.81\text{ m/s}^2)} = 183.5\text{ m}$$

Substitute numerical values in equation (2) and evaluate v_{y2}:

$$v_{y2} = \frac{183.5\text{ m} - \frac{1}{2}(9.81\text{ m/s}^2)(3.60\text{ s})^2}{3.60\text{ s}} = 33.31\text{ m/s}$$

Substitute numerical values in equation (1) and evaluate v_{y1}:

$$v_{y1} = 2(33.31\text{ m/s}) = 66.62\text{ m/s}$$

Express $\vec{v}_1$ in vector form:

$$\vec{v}_1 = v_{x1}\hat{i} + v_{y1}\hat{j} = \boxed{(312\text{ m/s})\hat{i} + (66.6\text{ m/s})\hat{j}}$$

(*b*) Express the total distance *d* traveled by the 1.00-kg fragment:

$$d = \Delta x + \Delta x' \qquad (3)$$

Relate Δx to v_0 and the time-to-explosion:

$$\Delta x = (v_0 \cos\theta)(\Delta t_{\text{exp}}) \qquad (4)$$

Using a constant-acceleration equation, express Δt_{exp}:

$$\Delta t_{\text{exp}} = \frac{v_{y0}}{g} = \frac{v_0 \sin\theta}{g}$$

Substitute numerical values and evaluate Δt_{exp}:

$$\Delta t_{\text{exp}} = \frac{(120\,\text{m/s})\sin 30.0°}{9.81\,\text{m/s}^2} = 6.116\,\text{s}$$

Substitute in equation (4) and evaluate Δx:

$$\Delta x = (120\,\text{m/s})(\cos 30.0°)(6.116\,\text{s}) = 635.6\,\text{m}$$

Relate the distance traveled by the 1.00-kg fragment after the explosion to the time it takes it to reach the ground:

$$\Delta x' = v_{x1}\Delta t'$$

Using a constant-acceleration equation, relate the time $\Delta t'$ for the 1.00-kg fragment to reach the ground to its initial speed in the *y* direction and the distance to the ground:

$$\Delta y = v_{y1}\Delta t' - \tfrac{1}{2}g(\Delta t')^2$$

Substitute to obtain the quadratic equation:

$$(\Delta t')^2 - (13.6\,\text{s})\Delta t' - 37.4\,\text{s}^2 = 0$$

Solve the quadratic equation to find $\Delta t'$:

$$\Delta t' = 15.945\text{ s}$$

Substitute in equation (3) and evaluate *d*:

$$\begin{aligned} d &= \Delta x + \Delta x' = \Delta x + v_{x1}\Delta t' \\ &= 635.6\,\text{m} + (312\,\text{m/s})(15.945\,\text{s}) \\ &= \boxed{5.6\,\text{km}} \end{aligned}$$

(*c*) Express the energy released in the explosion:

$$E_{\text{exp}} = \Delta K = K_{\text{f}} - K_{\text{i}} \qquad (5)$$

Find the kinetic energy of the fragments after the explosion:

$$K_f = K_1 + K_2 = \tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2$$
$$= \tfrac{1}{2}(1.00\,\text{kg})\left[(312\,\text{m/s})^2 + (66.6\,\text{m/s})^2\right]$$
$$+ \tfrac{1}{2}(2.00\,\text{kg})(33.3\,\text{m/s})^2$$
$$= 52.0\,\text{kJ}$$

Find the kinetic energy of the projectile before the explosion:

$$K_i = \tfrac{1}{2}m_3v_3^2 = \tfrac{1}{2}m_3(v_0\cos\theta)^2$$
$$= \tfrac{1}{2}(3.00\,\text{kg})\left[(120\,\text{m/s})\cos 30°\right]^2$$
$$= 16.2\,\text{kJ}$$

Substitute in equation (5) to determine the energy released in the explosion:

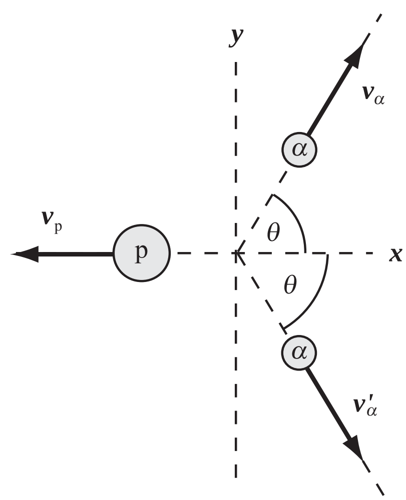
$$E_{\text{exp}} = K_f - K_i = 52.0\,\text{kJ} - 16.2\,\text{kJ}$$
$$= \boxed{35.8\,\text{kJ}}$$

76 ••• The boron isotope ^{9}B is unstable and disintegrates into a proton and two α particles. The total energy released as kinetic energy of the decay products is 4.4×10^{-14} J. After one such event, with the ^{9}B nucleus at rest prior to decay, the velocity of the proton is measured as 6.0×10^6 m/s. If the two α particles have equal energies, find the magnitude and the direction of their velocities with respect to the direction of the proton.

Picture the Problem This nuclear reaction is

$$^9\text{B} \rightarrow 2\alpha + \text{p} + 4.4\times10^{-14}\ \text{J}.$$

Assume that the proton moves in the $-x$ direction as shown in the diagram. The sum of the kinetic energies of the decay products equals the energy released in the decay. We'll use conservation of momentum to find the angle between the velocities of the proton and the alpha particles. Note that $v_\alpha = v'_\alpha$.



Express the energy released to the kinetic energies of the decay products:

$$K_p + 2K_\alpha = E_{\text{rel}}$$

or

$$\tfrac{1}{2}m_pv_p^2 + 2\left(\tfrac{1}{2}m_\alpha v_\alpha^2\right) = E_{\text{rel}}$$

Solving for v_α yields:

$$v_\alpha = \sqrt{\frac{E_{\text{rel}} - \frac{1}{2}m_p v_p^2}{m_\alpha}}$$

Substitute numerical values and evaluate v_α:

$$v_\alpha = \sqrt{\frac{4.4\times10^{-14}\ \text{J}}{6.64\times10^{-27}\ \text{kg}} - \frac{\frac{1}{2}(1.67\times10^{-27}\ \text{kg})(6.0\times10^{6}\ \text{m/s})^2}{6.64\times10^{-27}\ \text{kg}}} = 1.44\times10^{6}\ \text{m/s}$$
$$= \boxed{1.4\times10^{6}\ \text{m/s}}$$

Given that the boron isotope was at rest prior to the decay, use conservation of momentum to relate the momenta of the decay products:

$\vec{\boldsymbol{p}}_\text{f} = \vec{\boldsymbol{p}}_\text{i} = 0$
or, because $p_{x\text{f}} = 0$,
$2(m_\alpha v_\alpha \cos\theta) - m_p v_p = 0$

Substituting for m_α to obtain:

$$2(4m_p v_\alpha \cos\theta) - m_p v_p = 0$$

Solving for θ yields:

$$\theta = \cos^{-1}\left[\frac{v_p}{8v_\alpha}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \cos^{-1}\left[\frac{6.0\times10^{6}\ \text{m/s}}{8(1.44\times10^{6}\ \text{m/s})}\right] = \pm59°$$

Let θ' equal the angle the velocities of the alpha particles make with that of the proton:

$$\theta' = \pm(180° - 59°) = \boxed{\pm121°}$$

Coefficient of Restitution

77 • [SSM] You are in charge of measuring the coefficient of restitution for a new alloy of steel. You convince your engineering team to accomplish this task by simply dropping a small ball onto a plate, both the ball and plate made from the experimental alloy. If the ball is dropped from a height of 3.0 m and rebounds to a height of 2.5 m, what is the coefficient of restitution?

Picture the Problem The coefficient of restitution is defined as the ratio of the speed of recession to the speed of approach. These speeds can be determined from the height from which the ball was dropped and the height to which it rebounded by using conservation of mechanical energy.

Use its definition to relate the coefficient of restitution to the speeds of approach and recession:

$$e = \frac{v_{rec}}{v_{app}}$$

Letting $U_g = 0$ at the surface of the steel plate, apply conservation of energy to obtain:

$$\Delta K + \Delta U = 0$$
or, because $K_i = U_f = 0$,
$$K_f - U_i = 0$$

Substituting for K_f and U_i yields:

$$\tfrac{1}{2}mv_{app}^2 - mgh_{app} = 0$$

Solving for v_{app} yields:

$$v_{app} = \sqrt{2gh_{app}}$$

In like manner, show that:

$$v_{rec} = \sqrt{2gh_{rec}}$$

Substitute in the equation for e to obtain:

$$e = \frac{\sqrt{2gh_{rec}}}{\sqrt{2gh_{app}}} = \sqrt{\frac{h_{rec}}{h_{app}}}$$

Substitute numerical values and evaluate e:

$$e = \sqrt{\frac{2.5\,\text{m}}{3.0\,\text{m}}} = \boxed{0.91}$$

78 • According to the official racquetball rules, to be acceptable for tournament play, a ball must bounce to a height of between 173 and 183 cm when dropped from a height of 254 cm at room temperature. What is the acceptable range of values for the coefficient of restitution for the racquetball–floor system?

Picture the Problem The coefficient of restitution is defined as the ratio of the speed of recession to the speed of approach. These speeds can be determined from the heights from which the ball was dropped and the height to which it rebounded by using conservation of mechanical energy.

Use its definition to relate the coefficient of restitution to the speeds of approach and recession:

$$e = \frac{v_{rec}}{v_{app}}$$

Letting $U_g = 0$ at the surface of the steel plate, the mechanical energy of the ball-Earth system is:

$$\Delta K + \Delta U = 0$$
or, because $K_i = U_f = 0$,
$$K_f - U_i = 0$$

Substituting for K_f and U_i yields:

$$\tfrac{1}{2}mv_{app}^2 - mgh_{app} = 0 \Rightarrow v_{app} = \sqrt{2gh_{app}}$$

In like manner, show that: $v_{\text{rec}} = \sqrt{2gh_{\text{rec}}}$

Substitute in the equation for e to obtain:

$$e = \frac{\sqrt{2gh_{\text{rec}}}}{\sqrt{2gh_{\text{app}}}} = \sqrt{\frac{h_{\text{rec}}}{h_{\text{app}}}}$$

Substitute numerical values and evaluate e_{min}:

$$e_{\text{min}} = \sqrt{\frac{173\,\text{cm}}{254\,\text{cm}}} = 0.825$$

Substitute numerical values and evaluate e_{max}:

$$e_{\text{max}} = \sqrt{\frac{183\,\text{cm}}{254\,\text{cm}}} = 0.849$$

and $\boxed{0.825 \le e \le 0.849}$

79 •• A ball bounces to 80 percent of its original height. (*a*) What fraction of its mechanical energy is lost each time it bounces? (*b*) What is the coefficient of restitution of the ball–floor system?

Picture the Problem Because the rebound kinetic energy is proportional to the rebound height, the percentage of mechanical energy lost in one bounce can be inferred from knowledge of the rebound height. The coefficient of restitution is defined as the ratio of the speed of recession to the speed of approach. These speeds can be determined from the heights from which an object was dropped and the height to which it rebounded by using conservation of mechanical energy.

(*a*) We know, because the mechanical energy of the ball-Earth system is constant, that the kinetic energy of an object dropped from a given height h is proportional to h. If, for each bounce of the ball, $h_{\text{rec}} = 0.80h_{\text{app}}$, 20% of its mechanical energy is lost.

(*b*) Use its definition to relate the coefficient of restitution to the speeds of approach and recession:

$$e = \frac{v_{\text{rec}}}{v_{\text{app}}} \qquad (1)$$

Letting $U_g = 0$ at the surface from which the ball is rebounding, the mechanical energy of the ball is:

$\Delta K + \Delta U = 0$
or, because $K_i = U_f = 0$,
$K_f - U_i = 0$

Substituting for K_f and U_i yields:

$$\tfrac{1}{2}mv_{\text{app}}^2 - mgh_{\text{app}} = 0 \Rightarrow v_{\text{app}} = \sqrt{2gh_{\text{app}}}$$

In like manner, show that: $v_{\text{rec}} = \sqrt{2gh_{\text{rec}}}$

Substitute for v_{rec} and v_{app} in equation (1) to obtain:

$$e = \frac{\sqrt{2gh_{rec}}}{\sqrt{2gh_{app}}} = \sqrt{\frac{h_{rec}}{h_{app}}}$$

Substitute for $\frac{h_{rec}}{h_{app}}$ to obtain:

$$e = \sqrt{0.80} = \boxed{0.89}$$

80 •• A 2.0-kg object moving to the right at 6.0 m/s collides head-on with a 4.0-kg object that is initially at rest. After the collision, the 2.0-kg object is moving to the left at 1.0 m/s. (*a*) Find the velocity of the 4.0-kg object after the collision. (*b*) Find the energy lost in the collision. (*c*) What is the coefficient of restitution for these objects?

Picture the Problem Let the numerals 2 and 4 refer, respectively, to the 2.0-kg object and the 4.0-kg object. Choose a coordinate system in which the direction the 2.0-kg object is moving before the collision is the +*x* direction and let the system consist of Earth, the surface on which the objects slide, and the objects. Then we can use conservation of momentum to find the velocity of the recoiling 4.0-kg object. We can find the energy transformed in the collision by calculating the difference between the pre- and post-collision kinetic energies and find the coefficient of restitution from its definition.

(*a*) Use conservation of linear momentum in one dimension to relate the initial and final momenta of the participants in the collision:

$$\vec{\boldsymbol{p}}_i = \vec{\boldsymbol{p}}_f$$

or

$$m_2v_{2i} = m_4v_{4f} - m_2v_{2f}$$

Solve for the final velocity of the 4.0-kg object:

$$v_{4f} = \frac{m_2v_{2i} + m_2v_{2f}}{m_4}$$

Substitute numerical values and evaluate v_{4f}:

$$v_{4f} = \frac{(2.0\,\text{kg})(6.0\,\text{m/s} + 1.0\,\text{m/s})}{4.0\,\text{kg}} = 3.50\,\text{m/s} = \boxed{3.5\,\text{m/s}}$$

(*b*) Express the energy lost in terms of the kinetic energies before and after the collision:

$$\begin{aligned} E_{lost} &= K_i - K_f \\ &= \tfrac{1}{2}m_2v_{2i}^2 - \left(\tfrac{1}{2}m_2v_{2f}^2 + \tfrac{1}{2}m_4v_{4f}^2\right) \\ &= \tfrac{1}{2}\left[m_2\left(v_{2i}^2 - v_{2f}^2\right) - m_4v_{4f}^2\right] \end{aligned}$$

Substitute numerical values and evaluate E_{lost}:

$$E_{lost} = \tfrac{1}{2}\left[\left((2.0\,\text{kg})\left\{(6.0\,\text{m/s})^2 - (1.0\,\text{m/s})^2\right\}\right) - (4.0\,\text{kg})(3.50\,\text{m/s})^2\right] = \boxed{11\,\text{J}}$$

(*c*) From the definition of the coefficient of restitution we have:

$$e = \frac{v_{\text{rec}}}{v_{\text{app}}} = \frac{v_{4\text{f}} - v_{2\text{f}}}{v_{2\text{i}}}$$

Substitute numerical values and evaluate *e*:

$$e = \frac{3.50\,\text{m/s} - (-1.0\,\text{m/s})}{6.0\,\text{m/s}} = \boxed{0.75}$$

81 •• A 2.0-kg block moving to the right with speed of 5.0 m/s collides with a 3.0-kg block that is moving in the same direction at 2.0 m/s, as in Figure 8-49. After the collision, the 3.0-kg block moves to the right at 4.2 m/s. Find (*a*) the velocity of the 2.0-kg block after the collision and (*b*) the coefficient of restitution between the two blocks.

Picture the Problem Let the numeral 2 refer to the 2.0-kg block and the numeral 3 to the 3.0-kg block. Choose a coordinate system in which the direction the blocks are moving before the collision is the +*x* direction and let the system consist of Earth, the surface on which the blocks move, and the blocks. Then we can use conservation of momentum to find the speed of the 2.0-kg block after the collision. We can find the coefficient of restitution from its definition.

(*a*) Use conservation of linear momentum in one dimension to relate the initial and final momenta of the participants in the collision:

$$\vec{p}_{\text{i}} = \vec{p}_{\text{f}}$$

or

$$m_2 v_{2\text{i}} + m_3 v_{3\text{i}} = m_2 v_{2\text{f}} + m_3 v_{3\text{f}}$$

Solve for the final speed of the 2.0-kg object:

$$v_{2\text{f}} = \frac{m_2 v_{2\text{i}} + m_3 v_{3\text{i}} - m_3 v_{3\text{f}}}{m_2}$$

Substitute numerical values and evaluate $v_{2\text{f}}$:

$$v_{2\text{f}} = \frac{(2.0\,\text{kg})(5.0\,\text{m/s}) + (3.0\,\text{kg})(2.0\,\text{m/s} - 4.2\,\text{m/s})}{2.0\,\text{kg}} = 1.70\,\text{m/s} = \boxed{1.7\,\text{m/s}}$$

(*b*) From the definition of the coefficient of restitution we have:

$$e = \frac{v_{\text{rec}}}{v_{\text{app}}} = \frac{v_{3\text{f}} - v_{2\text{f}}}{v_{2\text{i}} - v_{3\text{i}}}$$

Substitute numerical values and evaluate *e*:

$$e = \frac{4.2\,\text{m/s} - 1.7\,\text{m/s}}{5.0\,\text{m/s} - 2.0\,\text{m/s}} = \boxed{0.83}$$

82 ••• To keep homerun records and distances consistent from year to year, organized baseball randomly checks the coefficient of restitution between new baseballs and wooden surfaces similar to that of an average bat. Suppose you are in charge of making sure that no "juiced" baseballs are produced. (*a*) In a random

test, you find one that when dropped from 2.0 m rebounds 0.25 m. What is the coefficient of restitution for this ball? (*b*) What is the maximum distance home run shot you would expect from this ball, neglecting any effects due to air resistance and making reasonable assumption for bat speeds and incoming pitch speeds? Is this a ″juiced″ ball, a ″normal″ ball, or a ″dead″ ball?

Picture the Problem The coefficient of restitution is defined as the ratio of the speed of recession to the speed of approach. These speeds can be determined from the heights from which the ball was dropped and the height to which it rebounded by using conservation of mechanical energy. We can use the same elevation range equation to find the maximum home run you would expect from the ball with the experimental coefficient of restitution.

(*a*) The coefficient of restitution is the ratio of the speeds of approach and recession:

$$e=\frac{v_{rec}}{v_{app}} \qquad (1)$$

Letting $U_g = 0$ at the surface of from which the ball rebounds, the mechanical energy of the ball-Earth system is:

$$\Delta K+\Delta U=0$$

or, because $K_i = U_f = 0$,

$$K_f-U_i=0$$

Substituting for K_f and U_i yields:

$$\tfrac{1}{2}mv_{app}^2-mgh_{app}=0\Rightarrow v_{app}=\sqrt{2gh_{app}}$$

In like manner, show that:

$$v_{rec}=\sqrt{2gh_{rec}}$$

Substitute for v_{rec} and v_{app} in equation (1) and simplify to obtain:

$$e=\frac{\sqrt{2gh_{rec}}}{\sqrt{2gh_{app}}}=\sqrt{\frac{h_{rec}}{h_{app}}}$$

Substitute numerical values and evaluate e:

$$e=\sqrt{\frac{0.25\,\text{m}}{2.0\,\text{m}}}=0.3536=\boxed{0.35}$$

(*b*) The ″same-elevation″ range equation is:

$$R=\frac{v_{rec}^2\sin 2\theta}{g}=\frac{e^2v_{app}^2\sin 2\theta}{g} \qquad (2)$$

v_{app} is the sum of the speed of the ball and the speed of the bat:

$$v_{app}=v_{ball}+v_{bat}$$

Assuming that the bat travels about 1 m in 0.2 s yields:

$$v_{bat}=\frac{1\,\text{m}}{0.2\,\text{s}}=5\text{ m/s}$$

Assuming that the speed of the baseball thrown by the pitcher is close to 100 mi/h yields:

$$v_{\text{ball}} \approx 45\ \text{m/s}$$

Evaluate v_{app} to obtain:

$$v_{\text{app}} = 45\ \text{m/s} + 5\ \text{m/s} = 50\ \text{m/s}$$

Assuming a 45° launch angle, substitute numerical values in equation (2) and evaluate R:

$$R = \frac{(0.3536)^2(50\ \text{m/s})^2 \sin 2(45°)}{9.81\ \text{m/s}^2} \approx \boxed{32\ \text{m}}$$

Because home runs must travel at least 100 m in modern major league ballparks, this is a ″dead″ ball and should be tossed out.

83 •• [SSM] To make puck handling easy, hockey pucks are kept frozen until they are used in the game. (*a*) Explain why room temperature pucks would be more difficult to handle on the end of a stick than a frozen puck. (*Hint: Hockey pucks are made of rubber*.) (*b*) A room-temperature puck rebounds 15 cm when dropped onto a wooden surface from 100 cm. If a frozen puck has only half the coefficient of restitution of a room-temperature one, predict how high the frozen puck would rebound under the same conditions.

Picture the Problem The coefficient of restitution is defined as the ratio of the speed of recession to the speed of approach. These speeds can be determined from the heights from which the ball was dropped and the height to which it rebounded by using conservation of mechanical energy.

(*a*) At room-temperature rubber will bounce more when it hits a stick than it will at freezing temperatures.

(*b*) The mechanical energy of the rebounding puck is constant:

$$\Delta K + \Delta U = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

If the puck's speed of recession is v_{rec} and it rebounds to a height h, then:

$$-\tfrac{1}{2}mv_{\text{rec}}^2 + mgh = 0 \Rightarrow h = \frac{v_{\text{rec}}^2}{2g}$$

The coefficient of restitution is the ratio of the speeds of approach and recession:

$$e = \frac{v_{\text{rec}}}{v_{\text{app}}} \Rightarrow v_{\text{rec}} = ev_{\text{app}} \qquad (1)$$

Substitute for v_{rec} to obtain: $$h = \frac{e^2 v_{app}^2}{2g} \qquad (2)$$

Letting $U_g = 0$ at the surface of from which the puck rebounds, the mechanical energy of the puck-Earth system is: $\Delta K + \Delta U = 0$

Because $K_i = U_f = 0$,

$K_f - U_i = 0$

Substituting for K_f and U_i yields: $$\tfrac{1}{2} m v_{app}^2 - mgh_{app} = 0 \Rightarrow v_{app} = \sqrt{2gh_{app}}$$

In like manner, show that: $$v_{rec} = \sqrt{2gh_{rec}}$$

Substitute for v_{rec} and v_{app} in equation (1) and simplify to obtain: $$e = \frac{\sqrt{2gh_{rec}}}{\sqrt{2gh_{app}}} = \sqrt{\frac{h_{rec}}{h_{app}}}$$

Substitute numerical values and evaluate $e_{room\ temp}$: $$e_{room\ temp} = \sqrt{\frac{15\,\text{cm}}{100\,\text{cm}}} = 0.3873$$

For the falling puck, v_{app} is given by: $$v_{app} = \sqrt{2gH}$$

where H is the height from which the puck was dropped.

Substituting for v_{app} in equation (2) and simplifying yields: $$h = \frac{2e^2 gH}{2g} = e^2 H \qquad (3)$$

For the room-temperature puck: $$e_{frozen} = \tfrac{1}{2} e_{room\ temp}$$

Substituting for e in equation (3) yields: $$h = \tfrac{1}{4} e_{room\ temp}^2 H$$

Substitute numerical values and evaluate h: $$h = \tfrac{1}{4}(0.3873)^2(100\ \text{cm}) = \boxed{3.8\,\text{cm}}$$

Remarks: The puck that rebounds only 3.8 cm is a much ″deader″ and, therefore, much better puck.

Collisions in More Than One Dimension

84 •• In Section 8-3 it was proven by using geometry that when a particle elastically collides with another particle of equal mass that is initially at rest, the

two post-collision velocities are perpendicular. Here we examine another way of proving this result that illustrates the power of vector notation. (*a*) Given that $\vec{\boldsymbol{A}} = \vec{\boldsymbol{B}} + \vec{\boldsymbol{C}}$, square both sides of this equation (obtain the scalar product of each side with itself) to show that $A^2 = B^2 + C^2 + 2\vec{\boldsymbol{B}}\cdot\vec{\boldsymbol{C}}$. (*b*) Let the momentum of the initially moving particle be $\vec{\boldsymbol{P}}$ and the momenta of the particles after the collision be $\vec{\boldsymbol{p}}_1$ and $\vec{\boldsymbol{p}}_2$. Write the vector equation for the conservation of linear momentum and square both sides (obtain the dot product of each side with itself). Compare it to the equation gotten from the elastic-collision condition (kinetic energy is conserved) and finally show that these two equations imply that $\vec{\boldsymbol{p}}_1 \cdot \vec{\boldsymbol{p}}_2 = 0$.

Picture the Problem We can use the definition of the magnitude of a vector and the definition of the scalar product to establish the result called for in (*a*). In Part (*b*) we can use the result of Part (*a*), the conservation of momentum, and the definition of an elastic collision (kinetic energy is conserved) to show that the particles separate at right angles.

(*a*) Find the dot product of $\vec{\boldsymbol{B}}+\vec{\boldsymbol{C}}$ with itself:

$$\left(\vec{\boldsymbol{B}}+\vec{\boldsymbol{C}}\right)\cdot\left(\vec{\boldsymbol{B}}+\vec{\boldsymbol{C}}\right)= B^2 + C^2 + 2\vec{\boldsymbol{B}}\cdot\vec{\boldsymbol{C}}$$

Because $\vec{\boldsymbol{A}} = \vec{\boldsymbol{B}}+\vec{\boldsymbol{C}}$:

$$\boldsymbol{A}^2 = \left|\vec{\boldsymbol{B}}+\vec{\boldsymbol{C}}\right|^2 = \left(\vec{\boldsymbol{B}}+\vec{\boldsymbol{C}}\right)\cdot\left(\vec{\boldsymbol{B}}+\vec{\boldsymbol{C}}\right)$$

Substitute for $\left(\vec{\boldsymbol{B}}+\vec{\boldsymbol{C}}\right)\cdot\left(\vec{\boldsymbol{B}}+\vec{\boldsymbol{C}}\right)$ to obtain:

$$\boxed{A^2 = B^2 + C^2 + 2\vec{\boldsymbol{B}}\cdot\vec{\boldsymbol{C}}}$$

(*b*) Apply conservation of momentum to the collision of the particles:

$$\vec{\boldsymbol{p}}_1 + \vec{\boldsymbol{p}}_2 = \vec{\boldsymbol{p}}$$

Form the scalar product of each side of this equation with itself to obtain:

$$\left(\vec{\boldsymbol{p}}_1 + \vec{\boldsymbol{p}}_2\right)\cdot\left(\vec{\boldsymbol{p}}_1 + \vec{\boldsymbol{p}}_2\right) = \vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{p}}$$

or

$$p_1^2 + p_2^2 + 2\vec{\boldsymbol{p}}_1\cdot\vec{\boldsymbol{p}}_2 = p^2 \qquad (1)$$

Use the definition of an elastic collision to obtain:

$$\frac{p_1^2}{2m} + \frac{p_2^2}{2m} = \frac{p^2}{2m}$$

or

$$p_1^2 + p_2^2 = p^2 \qquad (2)$$

Subtract equation (1) from equation (2) to obtain:

$$2\vec{\boldsymbol{p}}_1\cdot\vec{\boldsymbol{p}}_2 = 0 \text{ or } \boxed{\vec{\boldsymbol{p}}_1\cdot\vec{\boldsymbol{p}}_2 = 0}$$

That is, the particles move apart along paths that are at right angles to each other.

85 •• During a pool game, the cue ball, which has an initial speed of 5.0 m/s, makes an elastic collision with the eight ball, which is initially at rest. After the collision, the eight ball moves at an angle of 30º to the right of the original direction of the cue ball. Assume that the balls have equal masses. (*a*) Find the direction of motion of the cue ball immediately after the collision. (*b*) Find the speed of each ball immediately after the collision.

Picture the Problem Let the initial direction of motion of the cue ball be the +*x* direction. We can apply conservation of energy to determine the angle the cue ball makes with the +*x* direction and the conservation of momentum to find the final velocities of the cue ball and the eight ball.

(*a*) Use conservation of energy to relate the velocities of the collision participants before and after the collision:

$$\tfrac{1}{2}mv_{\text{ci}}^2 = \tfrac{1}{2}mv_{\text{cf}}^2 + \tfrac{1}{2}mv_8^2$$

or

$$v_{\text{ci}}^2 = v_{\text{cf}}^2 + v_8^2$$

This Pythagorean relationship tells us that $\vec{v}_{\text{ci}}$, $\vec{v}_{\text{cf}}$, and $\vec{v}_8$ form a right triangle. Hence:

$$\theta_{\text{cf}} + \theta_8 = 90°$$

and

$$\theta_{\text{cf}} = \boxed{60°}$$

(*b*) Use conservation of momentum in the *x* direction to relate the velocities of the collision participants before and after the collision:

$$\vec{p}_{\text{xi}} = \vec{p}_{\text{xf}}$$

or

$$mv_{\text{ci}} = mv_{\text{cf}}\cos\theta_{\text{cf}} + mv_8\cos\theta_8$$

Use conservation of momentum in the *y* direction to obtain a second equation relating the velocities of the collision participants before and after the collision:

$$\vec{p}_{\text{yi}} = \vec{p}_{\text{yf}}$$

or

$$0 = mv_{\text{cf}}\sin\theta_{\text{cf}} + mv_8\sin\theta_8$$

Solve these equations simultaneously to obtain:

$$v_{\text{cf}} = \boxed{2.50\,\text{m/s}} \text{ and } v_8 = \boxed{4.33\,\text{m/s}}$$

86 •• Object A, which has a mass *m* and a velocity $v_0\hat{\boldsymbol{i}}$ collides with object B, which has a mass 2*m* and a velocity $\tfrac{1}{2}v_0\hat{\boldsymbol{j}}$. Following the collision, object B has a velocity of $\tfrac{1}{4}v_0\hat{\boldsymbol{i}}$. (*a*) Determine the velocity of object A after the collision. (*b*) Is the collision elastic? If not, express the change in the kinetic energy in terms of *m* and v_0.

Picture the Problem We can find the final velocity of the object whose mass is *m* by using the conservation of momentum. Whether the collision was elastic can be decided by examining the difference between the initial and final kinetic energy of the interacting objects.

(*a*) Use conservation of linear momentum to relate the initial and final velocities of the two objects:

$$\vec{p}_\text{i} = \vec{p}_\text{f}$$
or
$$mv_0\hat{i} + 2m\left(\tfrac{1}{2}v_0\hat{j}\right) = 2m\left(\tfrac{1}{4}v_0\hat{i}\right) + m\vec{v}_{1\text{f}}$$

Simplify to obtain:

$$v_0\hat{i} + v_0\hat{j} = \tfrac{1}{2}v_0\hat{i} + \vec{v}_{1\text{f}}$$

Solving for $\vec{v}_{1\text{f}}$ yields:

$$\vec{v}_{1\text{f}} = \boxed{\tfrac{1}{2}v_0\hat{i} + v_0\hat{j}}$$

(*b*) Express the difference between the kinetic energy of the system before the collision and its kinetic energy after the collision:

$$\Delta E = K_\text{i} - K_\text{f} = K_{1\text{i}} + K_{2\text{i}} - \left(K_{1\text{f}} + K_{2\text{f}}\right)$$

Substituting for the kinetic energies yields:

$$\Delta E = \tfrac{1}{2}\left(mv_{1\text{i}}^2 + 2mv_{2\text{i}}^2 - mv_{1\text{f}}^2 - 2mv_{2\text{f}}^2\right)$$

Substitute for speeds and simplify to obtain:

$$\Delta E = \tfrac{1}{2}m\left[v_0^2 + 2\left(\tfrac{1}{4}v_0^2\right) - \tfrac{5}{4}v_0^2 - 2\left(\tfrac{1}{16}v_0^2\right)\right] = \boxed{\tfrac{1}{16}mv_0^2}$$

Because $\Delta E \neq 0$, the collision is inelastic.

87 •• **[SSM]** A puck of mass 5.0 kg moving at 2.0 m/s approaches an identical puck that is stationary on frictionless ice. After the collision, the first puck leaves with a speed v_1 at 30º to the original line of motion; the second puck leaves with speed v_2 at 60º, as in Figure 8-50. (*a*) Calculate v_1 and v_2. (*b*) Was the collision elastic?

Picture the Problem Let the direction of motion of the puck that is moving before the collision be the +*x* direction. Applying conservation of momentum to the collision in both the *x* and *y* directions will lead us to two equations in the unknowns v_1 and v_2 that we can solve simultaneously. We can decide whether the collision was elastic by either calculating the system's kinetic energy before and after the collision or by determining whether the angle between the final velocities is 90°.

(*a*) Use conservation of linear momentum in the *x* direction to obtain:

$p_{xi} = p_{xf}$

or

$$mv = mv_1 \cos 30° + mv_2 \cos 60°$$

Simplify further to obtain:

$$v = v_1 \cos 30° + v_2 \cos 60° \qquad (1)$$

Use conservation of momentum in the *y* direction to obtain a second equation relating the velocities of the collision participants before and after the collision:

$p_{yi} = p_{yf}$

or

$$0 = mv_1 \sin 30° - mv_2 \sin 60°$$

Simplifying further yields:

$$0 = v_1 \sin 30° - v_2 \sin 60° \qquad (2)$$

Solve equations (1) and (2) simultaneously to obtain:

$$v_1 = \boxed{1.7\,\text{m/s}} \text{ and } v_2 = \boxed{1.0\,\text{m/s}}$$

(*b*) Because the angle between $\vec{v}_1$ and $\vec{v}_2$ is 90°, the collision was elastic.

88 •• Figure 8-51 shows the result of a collision between two objects of unequal mass. (*a*) Find the speed v_2 of the larger mass after the collision and the angle θ_2. (*b*) Show that the collision is elastic.

Picture the Problem Let the direction of motion of the object that is moving before the collision be the +*x* direction. Applying conservation of momentum to the motion in both the *x* and *y* directions will lead us to two equations in the unknowns v_2 and θ_2 that we can solve simultaneously. We can show that the collision was elastic by showing that the system's kinetic energy before and after the collision is the same.

(*a*) Use conservation of linear momentum in the *x* direction to relate the velocities of the collision participants before and after the collision:

$p_{xi} = p_{xf}$

or

$$3mv_0 = \sqrt{5}mv_0 \cos\theta_1 + 2mv_2 \cos\theta_2$$

or

$$3v_0 = \sqrt{5}v_0 \cos\theta_1 + 2v_2 \cos\theta_2$$

Use conservation of linear momentum in the *y* direction to obtain a second equation relating the velocities of the collision participants before and after the collision:

$p_{yi} = p_{yf}$

or

$$0 = \sqrt{5}mv_0 \sin\theta_1 - 2mv_2 \sin\theta_2$$

Simplifying further yields:

$$0=\sqrt{5}v_0\sin\theta_1-2v_2\sin\theta_2$$

Note that if $\tan\theta_1 = 2$, then:

$$\cos\theta_1=\frac{1}{\sqrt{5}}\text{ and }\sin\theta_1=\frac{2}{\sqrt{5}}$$

Substitute in the x-direction momentum equation and simplify to obtain:

$$3v_0=\sqrt{5}v_0\frac{1}{\sqrt{5}}+2v_2\cos\theta_2$$

or

$$v_0=v_2\cos\theta_2 \qquad (1)$$

Substitute in the y-direction momentum equation and simplify to obtain:

$$0=\sqrt{5}v_0\frac{2}{\sqrt{5}}-2v_2\sin\theta_2$$

or

$$0=v_0-v_2\sin\theta_2 \qquad (2)$$

Solve equations (1) and (2) simultaneously for θ_2 :

$$\theta_2=\tan^{-1}(1)=\boxed{45.0°}$$

Substitute in equation (1) to find v_2:

$$v_2=\frac{v_0}{\cos\theta_2}=\frac{v_0}{\cos 45°}=\boxed{\sqrt{2}v_0}$$

(b) To show that the collision was elastic, find the before-collision and after-collision kinetic energies:

$$K_\text{i}=\tfrac{1}{2}m(3v_0)^2=4.5mv_0^2$$

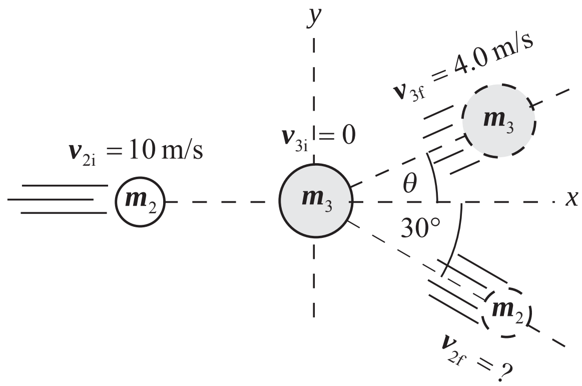
and

$$K_\text{f}=\tfrac{1}{2}m\left(\sqrt{5}v_0\right)^2+\tfrac{1}{2}(2m)\left(\sqrt{2}v_0\right)^2$$
$$=4.5mv_0^2$$

Because $K_\text{i} = K_\text{f}$, the collision is elastic.

89 •• A 2.0-kg ball moving at 10 m/s makes an off-center collision with a 3.0-kg ball that is initially at rest. After the collision, the 2.0-kg ball is deflected at an angle of 30º from its original direction of motion and the 3.0-kg ball is moving at 4.0 m/s. Find the speed of the 2.0-kg ball and the direction of the 3.0-kg ball after the collision. *Hint*: $\sin^2\alpha+\cos^2\alpha=1$.

Picture the Problem Let the direction of motion of the ball that is moving before the collision be the +x direction and use the subscripts 2 and 3 to designate the 2.0-kg and 3.0-kg balls, respectively. Applying conservation of momentum to the collision in both the x and y directions will lead us to two equations in the unknowns $\boldsymbol{v}_{2\text{f}}$ and θ that we can solve simultaneously.



Use conservation of momentum in the x and y directions to relate the speeds and directions of the balls before and after the collision:

$$m_2v_{2i} = m_2v_{2f}\cos 30° + m_3v_{3f}\sin\theta$$

and

$$0 = m_3v_{3f}\sin\theta - m_2v_{2f}\sin 30°$$

Solve the first of these equations for $\cos\theta$ to obtain:

$$\cos\theta = \frac{m_2v_{2i} - m_2v_{2f}\cos 30°}{m_3v_{3f}} \quad (1)$$

Solve the second of these equations for $\sin\theta$ to obtain:

$$\sin\theta = \frac{m_2v_{2f}\sin 30°}{m_3v_{3f}} \quad (2)$$

Using the hint given in the problem statement, square and add equations (1) and (2) and simplify the result to obtain the quadratic equation:

$$v_{2f}^2\sin^2 30° + \left(v_{2i} - v_{2f}\cos 30°\right)^2 = \frac{m_3^2v_{3f}^2}{m_2^2}$$

Substituting numerical values and simplifying yields:

$$v_{2f}^2 + \left(10\text{ m/s} - 0.866v_{2f}\right)^2 = 144\text{ m}^2/\text{s}^2$$

Use the quadratic formula or your graphing calculator to obtain:

$$v_{2f} = 5.344\text{ m/s or } 11.977\text{ m/s}$$

Because the larger of these values corresponds to there being more kinetic energy in the system after the collision than there was before the collision:

$$v_{2f} = \boxed{5.3\text{ m/s}}$$

Solving equation (2) for θ yields:

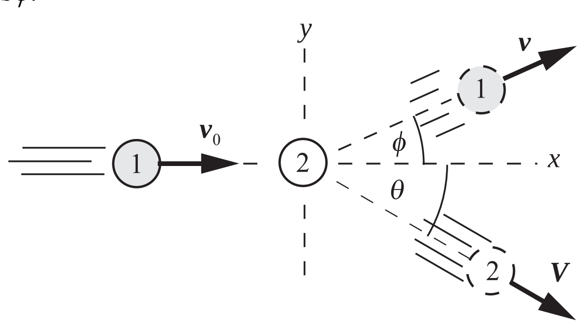
$$\theta = \sin^{-1}\left[\frac{m_2 v_{2f}\sin 30°}{m_3 v_{3f}}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{(2.0\ \text{kg})(5.344\ \text{m/s})\sin 30°}{(3.0\ \text{kg})(4.0\ \text{m/s})}\right] = \boxed{26°}$$

90 •• A particle has initial speed v_0. It collides with a second particle with the same mass that is initially at rest. The first particle is deflected through an angle ϕ. Its speed after the collision is v. The second particle recoils, and its velocity makes an angle θ with the initial direction of the first particle. (*a*) Show that $\tan\theta = \dfrac{v\sin\phi}{(v_0 - v\cos\phi)}$. (*b*) Show that if the collision is elastic, then $v = v_0\cos\phi$.

Picture the Problem Choose the coordinate system shown in the following diagram with the +*x* direction the direction of the initial approach of the projectile particle. Call *V* the speed of the target particle after the collision. In Part (*a*) we can apply conservation of momentum in the *x* and *y* directions to obtain two equations that we can solve simultaneously for $\tan\theta$. In Part (*b*) we can use conservation of momentum in vector form and the elastic-collision equation to show that $v = v_0\cos\phi$.



(*a*) Apply conservation of linear momentum in the *x* direction to obtain:

$$v_0 = v\cos\phi + V\cos\theta \qquad (1)$$

Apply conservation of linear momentum in the *y* direction to obtain:

$$v\sin\phi = V\sin\theta \qquad (2)$$

Solve equation (1) for $V\cos\theta$:

$$V\cos\theta = v_0 - v\cos\phi \qquad (3)$$

Divide equation (2) by equation (3) to obtain:

$$\frac{V\sin\theta}{V\cos\theta}=\frac{v\sin\phi}{v_0-v\cos\phi}$$

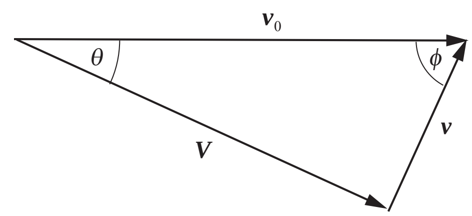
or

$$\tan\theta=\boxed{\frac{v\sin\phi}{v_0-v\cos\phi}}$$

(*b*) Noting that the masses of the particles are equal, apply conservation of linear momentum to obtain:

$$\vec{\boldsymbol{v}}_0=\vec{\boldsymbol{v}}+\vec{\boldsymbol{V}}$$

Draw the vector diagram representing this equation:



Use the definition of an elastic collision to obtain:

$$v_0^2=v^2+V^2$$

If this Pythagorean condition is to hold, the third angle of the triangle must be a right angle and, using the definition of the cosine function:

$$v=\boxed{v_0\cos\phi}$$

*Center-of-Mass Reference Frame

91 •• In the center-of-mass reference frame a particle with mass m_1 and momentum p_1 makes an elastic head-on collision with a second particle of mass m_2 and momentum $p_2 = -p_1$. After the collision its momentum is p_1'. Write the total kinetic energy in terms of m_1, m_2, and p_1 and the total final energy in terms of m_1, m_2, and p_1', and show that $p_1'=\pm p_1$. If $p_1'=-p_1$, the particle is merely turned around by the collision and leaves with the speed it had initially. What is the situation for the $p_1'=+p_1$ solution?

Picture the Problem The total kinetic energy of a system of particles is the sum of the kinetic energy of the center of mass and the kinetic energy relative to the center of mass. The kinetic energy of a particle of mass m is related to its momentum according to $K = p^2/2m$.

Express the total kinetic energy of the system:

$$K=K_{\text{rel}}+K_{\text{cm}} \qquad (1)$$

Relate the kinetic energy relative to the center of mass to the momenta of the two particles:

$$K_{\text{rel}} = \frac{p_1^2}{2m_1} + \frac{p_1^2}{2m_2} = \frac{p_1^2(m_1 + m_2)}{2m_1m_2}$$

Express the kinetic energy of the center of mass of the two particles:

$$K_{\text{cm}} = \frac{(2p_1)^2}{2(m_1 + m_2)} = \frac{2p_1^2}{m_1 + m_2}$$

Substitute in equation (1) and simplify to obtain:

$$K = \frac{p_1^2(m_1 + m_2)}{2m_1m_2} + \frac{2p_1^2}{m_1 + m_2}$$
$$= \frac{p_1^2}{2}\left[\frac{m_1^2 + 6m_1m_2 + m_2^2}{m_1^2m_2 + m_1m_2^2}\right]$$

In an elastic collision:

$$K_{\text{i}} = K_{\text{f}}$$
$$= \boxed{\frac{p_1^2}{2}\left[\frac{m_1^2 + 6m_1m_2 + m_2^2}{m_1^2m_2 + m_1m_2^2}\right]}$$
$$= \boxed{\frac{p_1'^2}{2}\left[\frac{m_1^2 + 6m_1m_2 + m_2^2}{m_1^2m_2 + m_1m_2^2}\right]}$$

Simplify to obtain:

$$(p_1')^2 = (p_1)^2 \Rightarrow \boxed{p_1' = \pm p_1}$$

and if $p_1' = +p_1$, the particles do not collide.

92 •• A 3.0-kg block is traveling in the $-x$ direction at 5.0 m/s, and a 1.0-kg block is traveling in the $+x$ direction at 3.0 m/s. (*a*) Find the velocity v_{cm} of the center of mass. (*b*) Subtract v_{cm} from the velocity of each block to find the velocity of each block in the center-of-mass reference frame. (*c*) After they make a head-on elastic collision, the velocity of each block is reversed (in the center-of-mass frame). Find the velocity of each block in the center-of-mass frame after the collision. (*d*) Transform back into the original frame by adding v_{cm} to the velocity of each block. (*e*) Check your result by finding the initial and final kinetic energies of the blocks in the original frame and comparing them.

Picture the Problem Let the numerals 3 and 1 denote the blocks whose masses are 3.0 kg and 1.0 kg respectively. We can use $\sum_i m_i\vec{v}_i = M\vec{v}_{\text{cm}}$ to find the velocity of the center-of-mass of the system and simply follow the directions in the problem step by step.

(*a*) Express the total momentum of this two-particle system in terms of the velocity of its center of mass:

$$\vec{P} = \sum_i m_i\vec{v}_i = m_1\vec{v}_1 + m_3\vec{v}_3$$
$$= M\vec{v}_{\text{cm}} = (m_1 + m_3)\vec{v}_{\text{cm}}$$

Solve for $\vec{v}_{\text{cm}}$:

$$\vec{v}_{\text{cm}} = \frac{m_3\vec{v}_3 + m_1\vec{v}_1}{m_3 + m_1}$$

Substitute numerical values and evaluate $\vec{v}_{\text{cm}}$:

$$\vec{v}_{\text{cm}} = \frac{(3.0\,\text{kg})(-5.0\,\text{m/s})\hat{i} + (1.0\,\text{kg})(3.0\,\text{m/s})\hat{i}}{3.0\,\text{kg} + 1.0\,\text{kg}} = \boxed{(-3.0\,\text{m/s})\hat{i}}$$

(*b*) Find the velocity of the 3-kg block in the center of mass reference frame:

$$\vec{u}_3 = \vec{v}_3 - \vec{v}_{\text{cm}}$$
$$= (-5.0\,\text{m/s})\hat{i} - (-3.0\,\text{m/s})\hat{i}$$
$$= \boxed{(-2.0\,\text{m/s})\hat{i}}$$

Find the velocity of the 1-kg block in the center of mass reference frame:

$$\vec{u}_1 = \vec{v}_1 - \vec{v}_{\text{cm}}$$
$$= (3.0\,\text{m/s})\hat{i} - (-3.0\,\text{m/s})\hat{i}$$
$$= \boxed{(6.0\,\text{m/s})\hat{i}}$$

(*c*) Express the after-collision velocities of both blocks in the center of mass reference frame:

$$\vec{u}_3' = \boxed{(2.0\,\text{m/s})\hat{i}}$$

and

$$\vec{u}_1' = \boxed{(-6.0\,\text{m/s})\hat{i}}$$

(*d*) Transform the after-collision velocity of the 3-kg block from the center of mass reference frame to the original reference frame:

$$\vec{v}_3' = \vec{u}_3' + \vec{v}_{\text{cm}}$$
$$= (2.0\,\text{m/s})\hat{i} + (-3.0\,\text{m/s})\hat{i}$$
$$= \boxed{(-1.0\,\text{m/s})\hat{i}}$$

Transform the after-collision velocity of the 1-kg block from the center of mass reference frame to the original reference frame:

$$\vec{v}_1' = \vec{u}_1' + \vec{v}_{\text{cm}}$$
$$= (-6.0\,\text{m/s})\hat{i} + (-3.0\,\text{m/s})\hat{i}$$
$$= \boxed{(-9.0\,\text{m/s})\hat{i}}$$

(*e*) Express K_{i} in the original frame of reference:

$$K_{\text{i}} = \tfrac{1}{2}m_3v_3^2 + \tfrac{1}{2}m_1v_1^2$$

Substitute numerical values and evaluate K_i:

$$K_\text{i} = \tfrac{1}{2}\left[(3.0\,\text{kg})(5.0\,\text{m/s})^2 + (1.0\,\text{kg})(3.0\,\text{m/s})^2\right] = \boxed{42\,\text{J}}$$

Express K_i in the original frame of reference:

$$K_\text{f} = \tfrac{1}{2}m_3v'^2_3 + \tfrac{1}{2}m_1v'^2_1$$

Substitute numerical values and evaluate K_f:

$$K_\text{f} = \tfrac{1}{2}\left[(3.0\,\text{kg})(1.0\,\text{m/s})^2 + (1.0\,\text{kg})(9.0\,\text{m/s})^2\right] = \boxed{42\,\text{J}}$$

93 •• [SSM] Repeat Problem 92 with the second block having a mass of 5.0 kg and moving to the right at 3.0 m/s.

Picture the Problem Let the numerals 3 and 5 denote the blocks whose masses are 3.0 kg and 5.0 kg respectively. We can use $\sum_i m_i\vec{v}_i = M\vec{v}_\text{cm}$ to find the velocity of the center-of-mass of the system and simply follow the directions in the problem step by step.

(*a*) Express the total momentum of this two-particle system in terms of the velocity of its center of mass:

$$\vec{P} = \sum_i m_i\vec{v}_i = m_3\vec{v}_3 + m_5\vec{v}_5 = M\vec{v}_\text{cm} = (m_3 + m_5)\vec{v}_\text{cm}$$

Solve for $\vec{v}_\text{cm}$:

$$\vec{v}_\text{cm} = \frac{m_3\vec{v}_3 + m_5\vec{v}_5}{m_3 + m_5}$$

Substitute numerical values and evaluate $\vec{v}_\text{cm}$:

$$\vec{v}_\text{cm} = \frac{(3.0\,\text{kg})(-5.0\,\text{m/s})\hat{i} + (5.0\,\text{kg})(3.0\,\text{m/s})\hat{i}}{3.0\,\text{kg} + 5.0\,\text{kg}} = \boxed{0}$$

(*b*) Find the velocity of the 3.0-kg block in the center of mass reference frame:

$$\vec{u}_3 = \vec{v}_3 - \vec{v}_\text{cm} = (-5.0\,\text{m/s})\,\hat{i} - 0 = \boxed{(-5.0\,\text{m/s})\,\hat{i}}$$

Find the velocity of the 5.0-kg block in the center of mass reference frame:

$$\vec{u}_5 = \vec{v}_5 - \vec{v}_\text{cm} = (3.0\,\text{m/s})\hat{i} - 0 = \boxed{(3.0\,\text{m/s})\hat{i}}$$

(*c*) Express the after-collision velocities of both blocks in the center of mass reference frame:

$$\vec{u}_3' = \boxed{(5.0\,\text{m/s})\hat{\boldsymbol{i}}}$$
and
$$\vec{u}_5' = \boxed{(-3.0\,\text{m/s})\hat{\boldsymbol{i}}}$$

(*d*) Transform the after-collision velocity of the 3.0-kg block from the center of mass reference frame to the original reference frame:

$$\vec{v}_3' = \vec{u}_3' + \vec{v}_{\text{cm}} = (5.0\,\text{m/s})\hat{\boldsymbol{i}} + 0$$
$$= \boxed{(5.0\,\text{m/s})\hat{\boldsymbol{i}}}$$

Transform the after-collision velocity of the 5.0-kg block from the center of mass reference frame to the original reference frame:

$$\vec{v}_5' = \vec{u}_5' + \vec{v}_{\text{cm}} = (-3.0\,\text{m/s})\hat{\boldsymbol{i}} + 0$$
$$= \boxed{(-3.0\,\text{m/s})\hat{\boldsymbol{i}}}$$

(*e*) Express K_{i} in the original frame of reference:

$$K_{\text{i}} = \tfrac{1}{2}m_3v_3^2 + \tfrac{1}{2}m_5v_5^2$$

Substitute numerical values and evaluate K_{i}:

$$K_{\text{i}} = \tfrac{1}{2}\left[(3.0\,\text{kg})(5.0\,\text{m/s})^2 + (5.0\,\text{kg})(3.0\,\text{m/s})^2\right] = \boxed{60\,\text{J}}$$

Express K_{f} in the original frame of reference:

$$K_{\text{f}} = \tfrac{1}{2}m_3v'^2_3 + \tfrac{1}{2}m_5v'^2_5$$

Substitute numerical values and evaluate K_{f}:

$$K_{\text{f}} = \tfrac{1}{2}\left[(3.0\,\text{kg})(5.0\,\text{m/s})^2 + (5.0\,\text{kg})(3.0\,\text{m/s})^2\right] = \boxed{60\,\text{J}}$$

*Systems With Continuously Varying Mass: Rocket Propulsion

94 • A rocket burns fuel at a rate of 200 kg/s and exhausts the gas at a relative speed of 6.00 km/s relative to the rocket. Find the magnitude of the thrust of the rocket.

Picture the Problem The thrust of a rocket F_{th} depends on the burn rate of its fuel *dm/dt* and the relative speed of its exhaust gases u_{ex} according to $F_{\text{th}} = |dm/dt|u_{\text{ex}}$.

Using its definition, relate the rocket's thrust to the relative speed of its exhaust gases:

$$F_{th} = \left|\frac{dm}{dt}\right| u_{ex}$$

Substitute numerical values and evaluate F_{th}:

$$F_{th} = (200\,\text{kg/s})(6.00\,\text{km/s})$$
$$= \boxed{1.20\,\text{MN}}$$

95 •• A rocket has an initial mass of 30,000 kg, of which 80 percent is the fuel. It burns fuel at a rate of 200 kg/s and exhausts its gas at a relative speed of 1.80 km/s. Find (*a*) the thrust of the rocket, (*b*) the time until burnout, and (*c*) its speed at burnout assuming it moves straight upward near the surface of Earth. Assume that *g* is constant and neglect any effects of air resistance.

Picture the Problem The thrust of a rocket F_{th} depends on the burn rate of its fuel *dm/dt* and the relative speed of its exhaust gases u_{ex} according to $F_{th} = |dm/dt| u_{ex}$. The final velocity v_f of a rocket depends on the relative speed of its exhaust gases u_{ex}, its payload to initial mass ratio m_f/m_0 and its burn time according to $v_f = -u_{ex} \ln(m_f/m_0) - gt_b$.

(*a*) Using its definition, relate the rocket's thrust to the relative speed of its exhaust gases:

$$F_{th} = \left|\frac{dm}{dt}\right| u_{ex}$$

Substitute numerical values and evaluate F_{th}:

$$F_{th} = (200\,\text{kg/s})(1.80\,\text{km/s})$$
$$= \boxed{360\,\text{kN}}$$

(*b*) Relate the time to burnout to the mass of the fuel and its burn rate:

$$t_b = \frac{m_{fuel}}{dm/dt} = \frac{0.8m_0}{dm/dt}$$

Substitute numerical values and evaluate t_b:

$$t_b = \frac{(0.80)(30{,}000\,\text{kg})}{200\,\text{kg/s}} = \boxed{120\,\text{s}}$$

(*c*) Relate the final velocity of a rocket to its initial mass, exhaust velocity, and burn time:

$$v_f = -u_{ex} \ln\left(\frac{m_f}{m_0}\right) - gt_b$$

Substitute numerical values and evaluate v_f:

$$v_f = -(1.80\,\text{km/s})\ln\left(\frac{1}{5}\right) - (9.81\,\text{m/s}^2)(120\,\text{s}) = \boxed{1.72\,\text{km/s}}$$

96 •• The *specific impulse* of a rocket propellant is defined as $I_{sp} = F_{th}/(Rg)$, where F_{th} is the thrust of the propellant, g the magnitude of free-fall acceleration, and R the rate at which the propellant is burned. The rate depends predominantly on the type and exact mixture of the propellant. (*a*) Show that the specific impulse has the dimension of time. (*b*) Show that $u_{ex} = gI_{sp}$, where u_{ex} is the relative speed of the exhaust. (*c*) What is the specific impulse (in seconds) of the propellant used in the Saturn V rocket of Example 8-16.

Picture the Problem We can use the dimensions of thrust, burn rate, and acceleration to show that the dimension of specific impulse is time. Combining the definitions of rocket thrust and specific impulse will lead us to $u_{ex} = gI_{sp}$.

(*a*) Express the dimension of specific impulse in terms of the dimensions of F_{th}, R, and g:

$$[I_{sp}] = \frac{[F_{th}]}{[R][g]} = \frac{\frac{\mathrm{M \cdot L}}{\mathrm{T}^2}}{\frac{\mathrm{M}}{\mathrm{T}} \cdot \frac{\mathrm{L}}{\mathrm{T}^2}} = \boxed{\mathrm{T}}$$

(*b*) From the definition of rocket thrust we have:

$$F_{th} = Ru_{ex} \Rightarrow u_{ex} = \frac{F_{th}}{R}$$

Substitute for F_{th} to obtain:

$$u_{ex} = \frac{RgI_{sp}}{R} = \boxed{gI_{sp}} \qquad (1)$$

(*c*) Solve equation (1) for I_{sp} and substitute for u_{ex} to obtain:

$$I_{sp} = \frac{F_{th}}{Rg}$$

From Example 8-21 we have:

$R = 1.384\times10^4$ kg/s
and
$F_{th} = 3.4\times10^6$ N

Substitute numerical values and evaluate I_{sp}:

$$I_{sp} = \frac{3.4\times10^6\ \mathrm{N}}{(1.384\times10^4\ \mathrm{kg/s})(9.81\,\mathrm{m/s^2})} = \boxed{25\,\mathrm{s}}$$

97 ••• [SSM] The initial *thrust-to-weight ratio* τ_0 of a rocket is $\tau_0 = F_{th}/(m_0 g)$, where F_{th} is the rocket's thrust and m_0 the initial mass of the rocket, including the propellant. (*a*) For a rocket launched straight up from Earth's surface, show that $\tau_0 = 1 + (a_0/g)$, where a_0 is the initial acceleration of the rocket. For manned rocket flight, τ_0 cannot be made much larger than 4 for the comfort and safety of the astronauts. (The astronauts will feel that their weight as the rocket lifts off is equal to τ_0 times their normal weight.) (*b*) Show that the final velocity of a rocket launched from Earth's surface, in terms of τ_0 and I_{sp} (see Problem 96) can be written as

$$v_{\mathrm{f}} = gI_{\mathrm{sp}}\left[1n\left(\frac{m_0}{m_{\mathrm{f}}}\right) - \frac{1}{\tau_0}\left(1 - \frac{m_{\mathrm{f}}}{m_0}\right)\right]$$

where m_{f} is the mass of the rocket (not including the spent propellant). (*c*) Using a **spreadsheet** program or **graphing calculator**, graph v_{f} as a function of the mass ratio m_0/m_{f} for I_{sp} = 250 s and τ_0 = 2 for values of the mass ratio from 2 to 10. (Note that the mass ratio cannot be less than 1.) (*d*) To lift a rocket into orbit, a final velocity after burnout of v_{f} = 7.0 km/s is needed. Calculate the mass ratio required of a single stage rocket to do this, using the values of specific impulse and thrust ratio given in Part (*b*). For engineering reasons, it is difficult to make a rocket with a mass ratio much greater than 10. Can you see why multistage rockets are usually used to put payloads into orbit around Earth?

Picture the Problem We can use the rocket equation and the definition of rocket thrust to show that $\tau_0 = 1 + a_0/g$. In Part (*b*) we can express the burn time t_{b} in terms of the initial and final masses of the rocket and the rate at which the fuel burns, and then use this equation to express the rocket's final velocity in terms of I_{sp}, τ_0, and the mass ratio m_0/m_{f}. In Part (*d*) we'll need to use trial-and-error methods or a graphing calculator to solve the transcendental equation giving v_{f} as a function of m_0/m_{f}.

(*a*) The rocket equation is:

$$-mg + Ru_{\mathrm{ex}} = ma$$

From the definition of rocket thrust we have:

$$F_{\mathrm{th}} = Ru_{\mathrm{ex}}$$

Substitute for Ru_{ex} to obtain:

$$-mg + F_{\mathrm{th}} = ma$$

Solve for F_{th} at takeoff:

$$F_{\mathrm{th}} = m_0 g + m_0 a_0$$

Divide both sides of this equation by $m_0 g$ to obtain:

$$\frac{F_{\mathrm{th}}}{m_0 g} = 1 + \frac{a_0}{g}$$

Because $\tau_0 = F_{\mathrm{th}}/(m_0 g)$:

$$\tau_0 = \boxed{1 + \frac{a_0}{g}}$$

(*b*) Use Equation 8-39 to express the final speed of a rocket that starts from rest with mass m_0:

$$v_{\mathrm{f}} = u_{\mathrm{ex}} \ln\left(\frac{m_0}{m_{\mathrm{f}}}\right) - gt_{\mathrm{b}}, \qquad (1)$$

where t_{b} is the burn time.

Express the burn time in terms of the burn rate R (assumed constant):

$$t_{\mathrm{b}} = \frac{m_0 - m_{\mathrm{f}}}{R} = \frac{m_0}{R}\left(1 - \frac{m_{\mathrm{f}}}{m_0}\right)$$

Multiply t_b by one in the form $\frac{gF_{th}}{gF_{th}}$ and simplify to obtain:

$$t_b = \frac{gF_{th}}{gF_{th}}\frac{m_0}{R}\left(1-\frac{m_f}{m_0}\right) = \frac{gm_0}{F_{th}}\frac{F_{th}}{gR}\left(1-\frac{m_f}{m_0}\right) = \frac{I_{sp}}{\tau_0}\left(1-\frac{m_f}{m_0}\right)$$

Substitute in equation (1):

$$v_f = u_{ex}\ln\left(\frac{m_0}{m_f}\right) - \frac{gI_{sp}}{\tau_0}\left(1-\frac{m_f}{m_0}\right)$$

From Problem 96 we have:

$$u_{ex} = gI_{sp},$$

where u_{ex} is the exhaust velocity of the propellant.

Substitute for u_{ex} and factor to obtain:

$$v_f = gI_{sp}\ln\left(\frac{m_0}{m_f}\right) - \frac{gI_{sp}}{\tau_0}\left(1-\frac{m_f}{m_0}\right) = \boxed{gI_{sp}\left[\ln\left(\frac{m_0}{m_f}\right) - \frac{1}{\tau_0}\left(1-\frac{m_f}{m_0}\right)\right]}$$

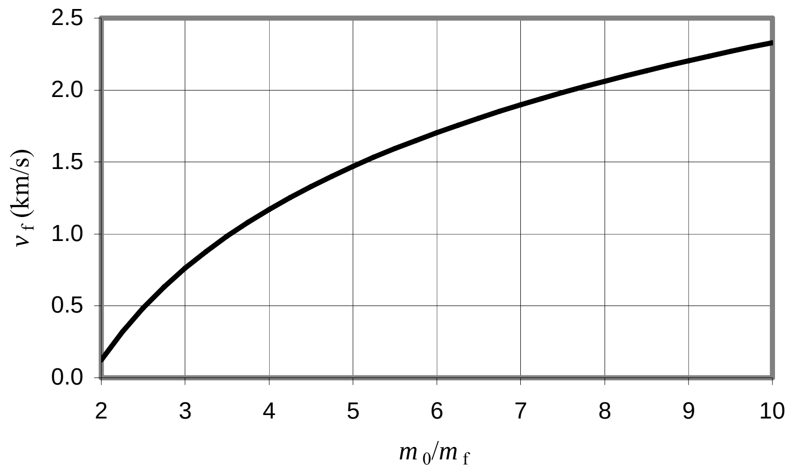
(*c*) A spreadsheet program to calculate the final velocity of the rocket as a function of the mass ratio m_0/m_f is shown below. The constants used in the velocity function and the formulas used to calculate the final velocity are as follows:

Cell	Content/Formula	Algebraic Form
B1	250	I_{sp}
B2	9.81	g
B3	2	τ_0
D9	D8 + 0.25	m_0/m_f
E8	\$B\$2*\$B\$1*(LOG(D8) – (1/\$B\$3)*(1/D8))	$gI_{sp}\left[\ln\left(\frac{m_0}{m_f}\right)-\frac{1}{\tau_0}\left(1-\frac{m_f}{m_0}\right)\right]$

	A	B	C	D	E
1	I_{sp} =	250	s		
2	g =	9.81	m/s^2		
3	τ_0=	2			
4					
5				mass ratio	v_f
6				2.00	1.252E+02
7				2.25	3.187E+02

8				2.50	4.854E+02
9				2.75	6.316E+02
10				3.00	7.614E+02
34				9.00	2.204E+03
35				9.25	2.237E+03
36				9.50	2.269E+03
37				9.75	2.300E+03
38				10.00	2.330E+03
39				725.00	7.013E+03

A graph of final velocity as a function of mass ratio follows.



(*d*) Substitute the data given in part (*c*) in the equation derived in Part (*b*) to obtain:

$$7.00\,\text{km/s} = \left(9.81\,\text{m/s}^2\right)\left(250\,\text{s}\right)\left(\ln\left(\frac{m_0}{m_f}\right) - \frac{1}{2}\left(1 - \frac{m_f}{m_0}\right)\right)$$

or

$$2.854 = \ln x - 0.5 + \frac{0.5}{x} \quad \text{where } x = m_0/m_f.$$

Use trial-and-error methods or a graphing calculator to solve this transcendental equation for the root greater than 1:

$\boldsymbol{x} \approx \boxed{28}$, a value considerably larger than the practical limit of 10 for single-stage rockets.

98 •• The height that a model rocket launched from Earth's surface can reach can be estimated by assuming that the burn time is short compared to the total flight time; the rocket is therefore in free-fall for most of the flight. (This estimate neglects the burn time in calculations of both time and displacement.) For a model rocket with specific impulse I_{sp} = 100 s, mass ratio m_0/m_f = 1.20, and

initial thrust-to-weight ratio τ_0 = 5.00 (these parameters are defined in Problems 96 and 97), estimate (*a*) the height the rocket can reach, and (*b*) the total flight time. (*c*) Justify the assumption used in the estimates by comparing the flight time from Part (*b*) to the time it takes to consume the fuel.

Picture the Problem We can use the velocity-at-burnout equation from Problem 96 to find v_f and constant-acceleration equations to approximate the maximum height the rocket will reach and its total flight time.

(*a*) Assuming constant acceleration, relate the maximum height reached by the model rocket to its time-to-top-of-trajectory:

$$h = \tfrac{1}{2} g t_{\text{top}}^2 \qquad (1)$$

From Problem 96 we have:

$$v_{\text{f}} = gI_{\text{sp}}\left(\ln\left(\frac{m_0}{m_{\text{f}}}\right) - \frac{1}{\tau}\left(1 - \frac{m_{\text{f}}}{m_0}\right)\right)$$

Evaluate the velocity at burnout v_f for I_{sp} = 100 s, m_0/m_f = 1.2, and τ = 5:

$$v_{\text{f}} = \left(9.81\,\text{m/s}^2\right)\left(100\,\text{s}\right)\left[\ln(1.2) - \frac{1}{5}\left(1 - \frac{1}{1.2}\right)\right] = 146\,\text{m/s}$$

Assuming that the time for the fuel to burn up is short compared to the total flight time, find the time to the top of the trajectory:

$$t_{\text{top}} = \frac{v_{\text{f}}}{g} = \frac{146\,\text{m/s}}{9.81\,\text{m/s}^2} = 14.9\,\text{s}$$

Substitute in equation (1) and evaluate *h*:

$$h = \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)\left(14.9\,\text{s}\right)^2 = \boxed{1.09\,\text{km}}$$

(*b*) Find the total flight time from the time it took the rocket to reach its maximum height:

$$t_{\text{flight}} = 2t_{\text{top}} = 2\left(14.9\,\text{s}\right) = \boxed{29.8\,\text{s}}$$

(*c*) The fuel burn time t_b is:

$$t_{\text{b}} = \frac{I_{sp}}{\tau}\left(1 - \frac{m_f}{m_0}\right) = \frac{100\,\text{s}}{5}\left(1 - \frac{1}{1.2}\right) = 3.33\,\text{s}$$

Because this burn time is approximately one-fifth of the total flight time, we can't expect the answer we obtain in Part (*b*) to be very accurate. It should, however, be good to about thirty percent accuracy, as the maximum distance the model rocket could possibly move in this time is $\frac{1}{2}v_f t_b = 244\text{ m}$, assuming constant acceleration until burnout.

General Problems

99 • [SSM] A 250-g model-train car traveling at 0.50 m/s links up with a 400-g car that is initially at rest. What is the speed of the cars immediately after they link up? Find the pre- and post-collision kinetic energies of the two-car system.

Picture the Problem Let the direction the 250-g car is moving before the collision be the +*x* direction. Let the numeral 1 refer to the 250-kg car, the numeral 2 refer to the 400-kg car, and *V* represent the velocity of the linked cars. Let the system include Earth and the cars. We can use conservation of momentum to find their speed after they have linked together and the definition of kinetic energy to find their pre- and post-collision kinetic energies.

Use conservation of momentum to relate the speeds of the cars immediately before and immediately after their collision:

$$p_{ix} = p_{fx}$$

or

$$m_1 v_1 = (m_1 + m_2)V \Rightarrow V = \frac{m_1 v_1}{m_1 + m_2}$$

Substitute numerical values and evaluate *V*:

$$V = \frac{(0.250\text{ kg})(0.50\text{ m/s})}{0.250\text{ kg} + 0.400\text{ kg}} = 0.192\text{ m/s}$$

$$= \boxed{0.19\text{ m/s}}$$

Find the pre-collision kinetic energy of the cars:

$$K_{\text{pre}} = \tfrac{1}{2}m_1 v_1^2 = \tfrac{1}{2}(0.250\text{ kg})(0.50\text{ m/s})^2$$

$$= \boxed{31\text{ mJ}}$$

Find the post-collision kinetic energy of the coupled cars:

$$K_{\text{post}} = \tfrac{1}{2}(m_1 + m_2)V^2$$

$$= \tfrac{1}{2}(0.250\text{ kg} + 0.400\text{ kg})(0.192\text{ m/s})^2$$

$$= \boxed{12\text{ mJ}}$$

100 • A 250-g model train car traveling at 0.50 m/s heads toward a 400-g car that is initially at rest. (*a*) Find the kinetic energy of the two-car system. (*b*) Find the velocity of each car in the center-of-mass reference frame, and use these velocities to calculate the kinetic energy of the two-car system in the center-of-

mass reference. (*c*) Find the kinetic energy associated with the motion of the center of mass of the system. (*d*) Compare your answer for Part (*a*) with the sum of your answers for Parts (*b*) and (*c*).

Picture the Problem Let the direction the 250-g car is moving before the collision be the +*x* direction. Let the numeral 1 refer to the 250-kg car and the numeral 2 refer to the 400-g car and the system include Earth and the cars. We can use conservation of momentum to find their speed after they have linked together and the definition of kinetic energy to find their pre- and post-collision kinetic energies.

(*a*) The pre-collision kinetic energy of the two-car system is:

$$K_{\text{pre}} = \tfrac{1}{2}m_1v_1^2 = \tfrac{1}{2}(0.250\,\text{kg})(0.50\,\text{m/s})^2 = 31.3\,\text{mJ} = \boxed{31\,\text{mJ}}$$

(*b*) Relate the velocity of the center of mass to the total momentum of the system:

$$\vec{\boldsymbol{P}}_{\text{sys}} = \sum_i m_i\vec{\boldsymbol{v}}_i = m\vec{\boldsymbol{v}}_{\text{cm}}$$

Solve for v_{cm}:

$$v_{\text{cm}} = \frac{m_1v_1 + m_2v_2}{m_1 + m_2}$$

Substitute numerical values and evaluate v_{cm}:

$$v_{\text{cm}} = \frac{(0.250\,\text{kg})(0.50\,\text{m/s})}{0.250\,\text{kg} + 0.400\,\text{kg}} = 0.192\,\text{m/s}$$

Find the initial velocity of the 250-g car relative to the velocity of the center of mass:

$$u_1 = v_1 - v_{\text{cm}} = 0.50\,\text{m/s} - 0.192\,\text{m/s} = \boxed{0.31\,\text{m/s}}$$

Find the initial velocity of the 400-g car relative to the velocity of the center of mass:

$$u_2 = v_2 - v_{\text{cm}} = 0\,\text{m/s} - 0.192\,\text{m/s} = \boxed{-0.19\,\text{m/s}}$$

Express the pre-collision kinetic energy of the system relative to the center of mass:

$$K_{\text{pre,rel}} = \tfrac{1}{2}m_1u_1^2 + \tfrac{1}{2}m_2u_2^2$$

Substitute numerical values and evaluate $K_{\text{pre,rel}}$:

$$K_{\text{pre,rel}} = \tfrac{1}{2}(0.250\,\text{kg})(0.308\,\text{m/s})^2 + \tfrac{1}{2}(0.400\,\text{kg})(-0.192\,\text{m/s})^2 = \boxed{19\,\text{mJ}}$$

(*c*) Express the kinetic energy of the center of mass:

$$K_{\rm cm} = \tfrac{1}{2}Mv_{\rm cm}^2$$

Substitute numerical values and evaluate $K_{\rm cm}$:

$$K_{\rm cm} = \tfrac{1}{2}(0.650\,\text{kg})(0.192\,\text{m/s})^2 = \boxed{12\,\text{mJ}}$$

(*d*) Relate the pre-collision kinetic energy of the system to its pre-collision kinetic energy relative to the center of mass and the kinetic energy of the center of mass:

$$K_{\rm i} = K_{\rm i,rel} + K_{\rm cm} = 19.2\,\text{mJ} + 12.0\,\text{mJ} = 31.2\,\text{mJ}$$

and

$$K_{\rm i} = \boxed{K_{\rm i,rel} + K_{\rm cm}}$$

101 •• A 1500-kg car traveling north at 70 km/h collides at an intersection with a 2000-kg car traveling west at 55 km/h. The two cars stick together. (*a*) What is the total momentum of the system before the collision? (*b*) Find the magnitude and direction of the velocity of the wreckage just after the collision.

Picture the Problem Let east be the positive *x* direction and north the positive *y* direction. Include both cars and Earth in the system and let the numeral 1 denote the 1500-kg car and the numeral 2 the 2000-kg car. Because the net external force acting on the system is zero, momentum is conserved in this perfectly inelastic collision.

(*a*) Express the total momentum of the system:

$$\vec{p} = \vec{p}_1 + \vec{p}_2 = m_1\vec{v}_1 + m_2\vec{v}_2 = m_1v_1\hat{j} - m_2v_2\hat{i}$$

Substitute numerical values and evaluate $\vec{p}$:

$$\begin{aligned}\vec{p} &= (1500\,\text{kg})(70\,\text{km/h})\hat{j} - (2000\,\text{kg})(55\,\text{km/h})\hat{i}\\ &= -(1.10\times10^5\,\text{kg}\cdot\text{km/h})\,\hat{i} + (1.05\times10^5\,\text{kg}\cdot\text{km/h})\hat{j}\\ &= \boxed{-(1.1\times10^5\,\text{kg}\cdot\text{km/h})\,\hat{i} + (1.1\times10^5\,\text{kg}\cdot\text{km/h})\hat{j}}\end{aligned}$$

(*b*) The velocity of the wreckage in terms of the total momentum of the system is given by:

$$\vec{v}_{\rm f} = \vec{v}_{\rm cm} = \frac{\vec{p}}{M}$$

Substitute numerical values and evaluate $\vec{v}_\text{f}$:

$$\vec{v}_\text{f} = \frac{-\left(1.10\times10^5\ \text{kg}\cdot\text{km/h}\right)\hat{i}}{1500\,\text{kg}+2000\,\text{kg}} + \frac{\left(1.05\times10^5\ \text{kg}\cdot\text{km/h}\right)\hat{j}}{1500\,\text{kg}+2000\,\text{kg}}$$
$$= -\left(31.4\,\text{km/h}\right)\hat{i} + \left(30.0\,\text{km/h}\right)\hat{j}$$

Find the magnitude of the velocity of the wreckage:

$$v_\text{f} = \sqrt{\left(31.4\,\text{km/h}\right)^2 + \left(30.0\,\text{km/h}\right)^2} = \boxed{43\,\text{km/h}}$$

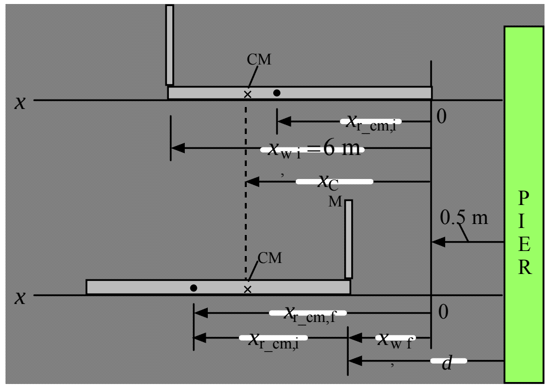
Find the direction the wreckage moves:

$$\theta = \tan^{-1}\left[\frac{30.0\,\text{km/h}}{-31.4\,\text{km/h}}\right] = -43.7°$$

The direction of the wreckage is 46° west of north.

102 •• A 60-kg woman stands on the back of a 6.0-m-long, 120-kg raft that is floating at rest in still water. The raft is 0.50 m from a fixed pier, as shown in Figure 8-52. (*a*) The woman walks to the front of the raft and stops. How far is the raft from the pier now? (*b*) While the woman walks, she maintains a constant speed of 3.0 m/s relative to the raft. Find the total kinetic energy of the system (woman plus raft), and compare with the kinetic energy if the woman walked at 3.0 m/s on a raft tied to the pier. (*c*) Where do these kinetic energies come from, and where do they go when the woman stops at the front of the raft? (*d*) On land, the woman puts a lead shot 6.0 m. She stands at the back of the raft, aims forward, and puts the shot so that just after it leaves her hand, it has the same velocity relative to her as it did when she threw it from the ground. Approximately, where does her shot land?

Picture the Problem Take the origin to be at the initial position of the right-hand end of raft and let the positive *x* direction be to the left. Let "*w*" denote the woman and "*r*" the raft, *d* be the distance of the end of the raft from the pier after the woman has walked to its front. The raft moves to the left as the woman moves to the right; with the center of mass of the woman-raft system remaining fixed (because $F_\text{ext,net} = 0$). The diagram shows the initial ($x_\text{w,i}$) and final ($x_\text{w,f}$) positions of the woman as well as the initial ($x_\text{r\_cm,i}$) and final ($x_\text{r\_cm,f}$) positions of the center of mass of the raft both before and after the woman has walked to the front of the raft.



(*a*) Express the distance of the raft from the pier after the woman has walked to the front of the raft:

$$d = 0.50\,\text{m} + x_{\text{w, f}} \qquad (1)$$

Express x_{cm} before the woman has walked to the front of the raft:

$$x_{\text{cm}} = \frac{m_{\text{w}} x_{\text{w,i}} + m_{\text{r}} x_{\text{r\_cm, i}}}{m_{\text{w}} + m_{\text{r}}}$$

Express x_{cm} after the woman has walked to the front of the raft:

$$x_{\text{cm}} = \frac{m_{\text{w}} x_{\text{w,f}} + m_{\text{r}} x_{\text{r\_cm,f}}}{m_{\text{w}} + m_{\text{r}}}$$

Because $F_{\text{ext,net}} = 0$, the center of mass remains fixed and we can equate these two expressions for x_{cm} to obtain:

$$m_{\text{w}} x_{\text{w,i}} + m_{\text{r}} x_{\text{r\_cm,i}} = m_{\text{w}} x_{\text{w,f}} + m_{\text{r}} x_{\text{r\_cm,f}}$$

Solve for $\boldsymbol{x}_{\text{w,f}}$:

$$x_{\text{w,f}} = x_{\text{w,i}} - \frac{m_{\text{r}}}{m_{\text{w}}}\left(x_{\text{r\_cm,f}} - x_{\text{r\_cm,i}}\right)$$

From the figure it can be seen that $\boldsymbol{x}_{\text{r\_cm,f}} - \boldsymbol{x}_{\text{r\_cm,i}} = \boldsymbol{x}_{\text{w,f}}$. Substitute $\boldsymbol{x}_{\text{w,f}}$ for $\boldsymbol{x}_{\text{r\_cm,f}} - \boldsymbol{x}_{\text{r\_cm,i}}$ to obtain:

$$x_{\text{w,f}} = \frac{m_{\text{w}} x_{\text{w,i}}}{m_{\text{w}} + m_{\text{r}}}$$

Substitute numerical values and evaluate $\boldsymbol{x}_{\text{w,f}}$:

$$\boldsymbol{x}_{\text{w,f}} = \frac{(60\,\text{kg})(6.0\,\text{m})}{60\,\text{kg} + 120\,\text{kg}} = 2.0\,\text{m}$$

Substitute in equation (1) to obtain:

$$d = 2.0\,\text{m} + 0.50\,\text{m} = \boxed{2.5\,\text{m}}$$

(*b*) Express the total kinetic energy of the system:

$$K_{\text{tot}} = \tfrac{1}{2} m_{\text{w}} v_{\text{w}}^2 + \tfrac{1}{2} m_{\text{r}} v_{\text{r}}^2$$

Noting that the elapsed time is 2.0 s, find v_w and v_r:

$$v_w = \frac{x_{w,f} - x_{w,i}}{\Delta t} = \frac{2.0\,\text{m} - 6.0\,\text{m}}{2.0\,\text{s}} = -2.0\,\text{m/s}$$

relative to the dock, and

$$v_r = \frac{x_{r,f} - x_{r,i}}{\Delta t} = \frac{2.50\,\text{m} - 0.50\,\text{m}}{2.0\,\text{s}} = 1.0\,\text{m/s}$$

also relative to the dock.

Substitute numerical values and evaluate K_{tot}:

$$K_{tot} = \tfrac{1}{2}(60\,\text{kg})(-2.0\,\text{m/s})^2 + \tfrac{1}{2}(120\,\text{kg})(1.0\,\text{m/s})^2 = \boxed{0.18\,\text{kJ}}$$

Evaluate K with the raft tied to the pier:

$$K_{tot} = \tfrac{1}{2}m_w v_w^2 = \tfrac{1}{2}(60\,\text{kg})(3.0\,\text{m/s})^2 = \boxed{0.27\,\text{kJ}}$$

(*c*) All the kinetic energy derives from the chemical energy of the woman and, assuming she stops via static friction, the kinetic energy is transformed into her internal energy.

(*d*) After the shot leaves the woman's hand, the raft-woman system constitutes an inertial reference frame. In that frame, the shot has the same initial velocity as did the shot that had a range of 6.0 m in the reference frame of the land. Thus, in the raft-woman frame, the shot also has a range of 6.0 m and lands at the front of the raft.

103 •• A 1.0-kg steel ball and a 2.0-m cord of negligible mass make up a simple pendulum that can pivot without friction about the point *O*, as in Figure 8-53. This pendulum is released from rest in a horizontal position and when the ball is at its lowest point it strikes a 1.0-kg block sitting at rest on a shelf. Assume that the collision is perfectly elastic and take the coefficient of kinetic friction between the block and shelf to be 0.10. (*a*) What is the velocity of the block just after impact? (*b*) How far does the block slide before coming to rest (assuming the shelf is long enough)?

Picture the Problem Let the zero of gravitational potential energy be at the elevation of the 1.0-kg block. We can use conservation of energy to find the speed of the bob just before its perfectly elastic collision with the block and

conservation of momentum to find the speed of the block immediately after the collision. We'll apply Newton's second law to find the acceleration of the sliding block and use a constant-acceleration equation to find how far it slides before coming to rest.

(*a*) Use conservation of energy to find the speed of the bob just before its collision with the block:

$$\Delta K + \Delta U = 0$$
or
$$K_f - K_i + U_f - U_i = 0$$

Because $K_i = U_f = 0$:

$$\tfrac{1}{2} m_{ball} v_{ball}^2 + m_{ball} g\Delta h = 0$$
and
$$v_{ball} = \sqrt{2g\Delta h}$$

Substitute numerical values and evaluate v_{ball}:

$$v_{ball} = \sqrt{2(9.81\,\text{m/s}^2)(2.0\,\text{m})} = 6.26\text{ m/s}$$

Because the collision is perfectly elastic and the ball and block have the same mass:

$$v_{block} = v_{ball} = \boxed{6.3\,\text{m/s}}$$

(*b*) Using a constant-acceleration equation, relate the displacement of the block to its acceleration and initial speed:

$$v_f^2 = v_i^2 + 2a_{block}\Delta x$$
or, because $v_f = 0$,
$$0 = v_i^2 + 2a_{block}\Delta x$$

Solving for Δx yields:

$$\Delta x = \frac{-v_i^2}{2a_{block}} = \frac{-v_{block}^2}{2a_{block}}$$

Apply $\sum \vec{F} = m\vec{a}$ to the sliding block:

$$\sum F_x = -f_k = ma_{block}$$
and
$$\sum F_y = F_n - m_{block} g = 0$$

Using the definition of f_k ($=\mu_k F_n$) eliminate f_k and F_n between the two equations and solve for a_{block}:

$$a_{block} = -\mu_k g$$

Substitute for a_{block} to obtain:

$$\Delta x = \frac{-v_{block}^2}{-2\mu_k g} = \frac{v_{block}^2}{2\mu_k g}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{(6.26\,\text{m/s})^2}{2(0.10)(9.81\,\text{m/s}^2)} = \boxed{20\,\text{m}}$$

104 •• Figure 8-54 shows a World War I cannon mounted on a railcar so that it will project a shell at an angle of 30º. With the car initially at rest, the cannon fires a 200-kg projectile at 125 m/s. (All values are for the frame of reference of the track.) Now consider a system composed of a cannon, shell, and railcar, all on the frictionless track. (*a*) Will the total vector momentum of that system be the same just before and just after the shell is fired? Explain your answer. (*b*) If the mass of the railcar plus cannon is 5000 kg, what will be the recoil velocity of the car along the track after the firing? (*c*) The shell is observed to rise to a maximum height of 180 m as it moves through its trajectory. At this point, its speed is 80.0 m/s. On the basis of this information, calculate the amount of thermal energy produced by air friction on the shell on its way from firing to this maximum height.

Picture the Problem We can use conservation of momentum in the horizontal direction to find the recoil velocity of the car along the track after the firing. Because the shell will neither rise as high nor be moving as fast at the top of its trajectory as it would be in the absence of air friction, we can apply the work-energy theorem to find the amount of thermal energy produced by the air friction.

(*a*) No. The vertical reaction force of the rails is an external force and so the momentum of the system will not be conserved.

(*b*) Use conservation of momentum in the horizontal (x) direction to obtain:

$$\Delta p_x = 0$$

or

$$mv\cos 30° - Mv_{\text{recoil}} = 0$$

Solving for v_{recoil} yields:

$$v_{\text{recoil}} = \frac{mv\cos 30°}{M}$$

Substitute numerical values and evaluate v_{recoil}:

$$v_{\text{recoil}} = \frac{(200\,\text{kg})(125\,\text{m/s})\cos 30°}{5000\,\text{kg}} = \boxed{4.3\,\text{m/s}}$$

(*c*) Using the work-energy theorem, relate the thermal energy produced by air friction to the change in the energy of the system:

$$W_{\text{ext}} = W_{\text{f}} = \Delta E_{\text{sys}} = \Delta U + \Delta K$$

Substitute for ΔU and ΔK to obtain:

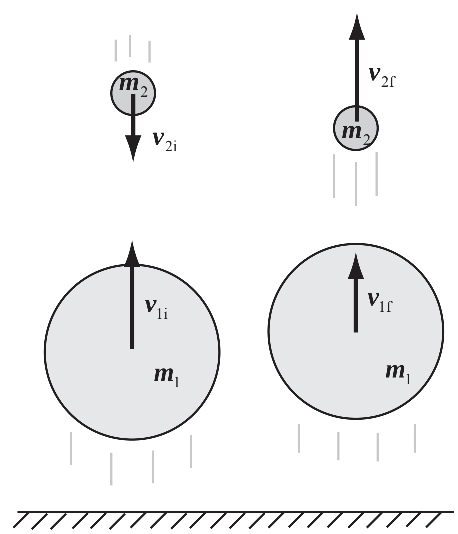
$$W_{\text{ext}} = mgy_{\text{f}} - mgy_{\text{i}} + \tfrac{1}{2}mv_{\text{f}}^2 - \tfrac{1}{2}mv_i^2$$
$$= mg\left(y_{\text{f}} - y_{\text{i}}\right) + \tfrac{1}{2}m\left(v_{\text{f}}^2 - v_i^2\right)$$

Substitute numerical values and evaluate W_{ext}:

$$W_{\text{ext}} = (200\,\text{kg})\left(9.81\,\text{m/s}^2\right)(180\,\text{m}) + \tfrac{1}{2}(200\,\text{kg})\left[(80.0\,\text{m/s})^2 - (125\,\text{m/s})^2\right]$$
$$= \boxed{-569\,\text{kJ}}$$

105 ••• [SSM] One popular, if dangerous, classroom demonstration involves holding a baseball an inch or so directly above a basketball, holding the basketball a few feet above a hard floor, and dropping the two balls simultaneously. The two balls will collide just after the basketball bounces from the floor; the baseball will then rocket off into the ceiling tiles with a hard "thud" while the basketball will stop in midair. (The author of this problem once broke a light doing this.)
(*a*) Assuming that the collision of the basketball with the floor is elastic, what is the relation between the velocities of the balls just before they collide?
(*b*) Assuming the collision between the two balls is elastic, use the result of Part (*a*) and the conservation of momentum and energy to show that, if the basketball is three times as heavy as the baseball, the final velocity of the basketball will be zero. (This is approximately the true mass ratio, which is why the demonstration is so dramatic.) (*c*) If the speed of the baseball is *v* just before the collision, what is its speed just after the collision?

Picture the Problem Let the numeral 1 refer to the basketball and the numeral 2 to the baseball. The left-hand side of the diagram shows the balls after the basketball's elastic collision with the floor and just before they collide. The right-hand side of the diagram shows the balls just after their collision. We can apply conservation of momentum and the definition of an elastic collision to obtain equations relating the initial and final velocities of the colliding balls that we can solve for $v_{1\text{f}}$ and $v_{2\text{f}}$.



(*a*) Because both balls are in free-fall, and both are in the air for the same amount of time, they have the same velocity just before the basketball rebounds. After the basketball rebounds elastically, its velocity will have the same magnitude, but the opposite direction than just before it hit the ground. The velocity of the basketball will be equal in magnitude but opposite in direction to the velocity of the baseball.

(*b*) Apply conservation of linear momentum to the collision of the balls to obtain:

$$m_1v_{1\text{f}} + m_2v_{2\text{f}} = m_1v_{1\text{i}} + m_2v_{2\text{i}} \quad (1)$$

Use conservation of mechanical energy to set the speed of recession equal to the negative of the speed of approach:

$$v_{2\text{f}} - v_{1\text{f}} = -(v_{1\text{i}} - v_{2\text{i}})$$
or
$$v_{1\text{f}} - v_{2\text{f}} = v_{2\text{i}} - v_{1\text{i}} \quad (2)$$

Multiply equation (2) by m_2 and add it to equation (1) to obtain:

$$(m_1 + m_2)v_{1\text{f}} = (m_1 - m_2)v_{1\text{i}} + 2m_2v_{2\text{i}}$$

Solve for $v_{1\text{f}}$ to obtain:

$$v_{1\text{f}} = \frac{m_1 - m_2}{m_1 + m_2}v_{1\text{i}} + \frac{2m_2}{m_1 + m_2}v_{2\text{i}}$$

or, because $v_{2\text{i}} = -v_{1\text{i}}$,

$$v_{1\text{f}} = \frac{m_1 - m_2}{m_1 + m_2}v_{1\text{i}} - \frac{2m_2}{m_1 + m_2}v_{1\text{i}} = \frac{m_1 - 3m_2}{m_1 + m_2}v_{1\text{i}}$$

For $m_1 = 3m_2$ and $v_{1\text{i}} = v$:

$$v_{1\text{f}} = \frac{3m_2 - 3m_2}{3m_2 + m_2}v = \boxed{0}$$

(*c*) Multiply equation (2) by m_1 and subtract it from equation (1) to obtain:

$$(m_1 + m_2)v_{2\text{f}} = (m_2 - m_1)v_{2\text{i}} + 2m_1v_{1\text{i}}$$

Solve for $v_{2\text{f}}$ to obtain:

$$v_{2\text{f}} = \frac{2m_1}{m_1 + m_2}v_{1\text{i}} + \frac{m_2 - m_1}{m_1 + m_2}v_{2\text{i}}$$

or, because $v_{2\text{i}} = -v_{1\text{i}}$,

$$v_{2\text{f}} = \frac{2m_1}{m_1 + m_2}v_{1\text{i}} - \frac{m_2 - m_1}{m_1 + m_2}v_{1\text{i}} = \frac{3m_1 - m_2}{m_1 + m_2}v_{1\text{i}}$$

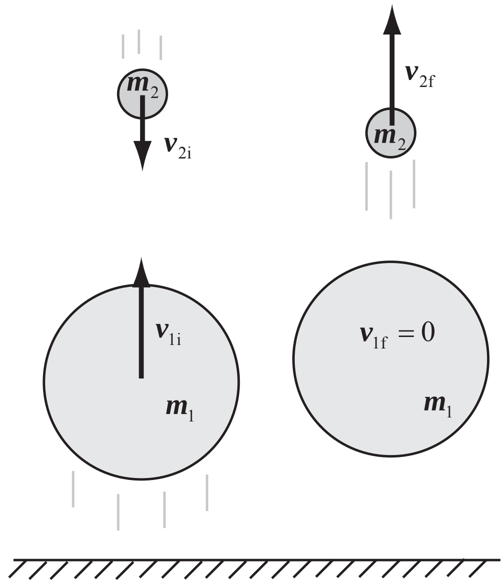
For $m_1 = 3m_2$ and $v_{1\text{i}} = v$:

$$v_{2\text{f}} = \frac{3(3m_2) - m_2}{3m_2 + m_2}v = \boxed{2v}$$

106 ••• (*a*) Referring to Problem 105, if we held a third ball above the baseball and basketball, and wanted both the basketball and baseball to stop in mid-air, what should the ratio of the mass of the top ball to the mass of the baseball be?

(*b*) If the speed of the top ball is *v* just before the collision, what is its speed just after the collision?

Picture the Problem In Problem 105 only two balls are dropped. They collide head on, each moving at speed *v*, and the collision is elastic. In this problem, as it did in Problem 105, the solution involves using the conservation of momentum equation $m_1v_{1f} + m_2v_{2f} = m_1v_{1i} + m_2v_{2i}$ and the elastic collision equation $v_{1f} - v_{2f} = v_{2i} - v_{1i}$ where the numeral 1 refers to the baseball, and the numeral 2 to the top ball. The diagram shows the balls just before and just after their collision. From Problem 105 we know that $v_{1i} = 2v$ and $v_{2i} = -v$.



(*a*) Express the final speed v_{1f} of the baseball as a function of its initial speed v_{1i} and the initial speed of the top ball v_{2i} (see Problem 64):

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2}v_{1i} + \frac{2m_2}{m_1 + m_2}v_{2i}$$

Substitute for v_{1i} and , v_{2i} to obtain:

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2}(2v) + \frac{2m_2}{m_1 + m_2}(-v)$$

Divide the numerator and denominator of each term by m_2 to introduce the mass ratio of the upper ball to the lower ball:

$$v_{1f} = \frac{\frac{m_1}{m_2} - 1}{\frac{m_1}{m_2} + 1}(2v) + \frac{2}{\frac{m_1}{m_2} + 1}(-v)$$

Set the final speed of the baseball v_{1f} equal to zero and let *x* represent the mass ratio m_1/m_2 to obtain:

$$0 = \frac{x-1}{x+1}(2v) + \frac{2}{x+1}(-v)$$

Solving for *x* yields:

$$x = \frac{m_1}{m_2} = \boxed{\tfrac{1}{2}}$$

(*b*) Apply the second of the two equations in Problem 64 to the collision between the top ball and the baseball:

$$v_{2f} = \frac{2m_1}{m_1 + m_2}v_{1i} + \frac{m_2 - m_1}{m_1 + m_2}v_{2i}$$

Substitute $v_{1i} = 2v$ and $v_{2i} = -v$ to obtain:

$$v_{2f} = \frac{2m_1}{m_1 + m_2}(2v) + \frac{m_2 - m_1}{m_1 + m_2}(-v)$$

In part (*a*) we showed that $m_2 = 2m_1$. Substitute and simplify to obtain:

$$v_{3f} = \frac{2(2m_1)}{m_1 + 2m_1}(2v) - \frac{2m_1 - m_1}{m_1 + 2m_1}v = \boxed{\tfrac{7}{3}v}$$

107 ••• [SSM] In the "slingshot effect," the transfer of energy in an elastic collision is used to boost the energy of a space probe so that it can escape from the solar system. All speeds are relative to an inertial frame in which the center of the sun remains at rest. Figure 8-55 shows a space probe moving at 10.4 km/s toward Saturn, which is moving at 9.6 km/s toward the probe. Because of the gravitational attraction between Saturn and the probe, the probe swings around Saturn and heads back in the opposite direction with speed v_f. (*a*) Assuming this collision to be a one-dimensional elastic collision with the mass of Saturn much greater than that of the probe, find v_f. (*b*) By what factor is the kinetic energy of the probe increased? Where does this energy come from?

Picture the Problem Let the direction the probe is moving after its elastic collision with Saturn be the positive direction. The probe gains kinetic energy at the expense of the kinetic energy of Saturn. We'll relate the speed of approach relative to the center of mass to u_{rec} and then to v. The $+x$ direction is also the direction of the motion of Saturn.

(*a*) Relate the speed of recession to the speed of recession relative to the center of mass:

$$v = u_{rec} + v_{cm} \quad (1)$$

Find the speed of approach:

$$u_{app} = -9.6\,\text{km/s} - 10.4\,\text{km/s} = -20.0\,\text{km/s}$$

Relate the relative speed of approach to the relative speed of recession for an elastic collision:

$$u_{rec} = -u_{app} = 20.0\,\text{km/s}$$

Because Saturn is so much more massive than the space probe:

$$v_{cm} = v_{Saturn} = 9.6\,\text{km/s}$$

Substitute numerical values in equation (1) and evaluate v:

$$v = 20\,\text{km/s} + 9.6\,\text{km/s} = \boxed{30\,\text{km/s}}$$

(*b*) Express the ratio of the final kinetic energy to the initial kinetic energy and simplify:

$$\frac{K_f}{K_i}=\frac{\frac{1}{2}Mv_{rec}^2}{\frac{1}{2}Mv_i^2}=\left(\frac{v_{rec}}{v_i}\right)^2$$

Substitute numerical values and evaluate K_f/K_i:

$$\frac{K_f}{K_i}=\left(\frac{29.6\,\text{km/s}}{10.4\,\text{km/s}}\right)^2=\boxed{8.1}$$

The energy comes from an immeasurably small slowing of Saturn.

108 •• A 13-kg block is at rest on a level floor. A 400-g glob of putty is thrown at the block so that the putty travels horizontally, hits the block, and sticks to it. The block and putty slide 15 cm along the floor. If the coefficient of kinetic friction is 0.40, what is the initial speed of the putty?

Picture the Problem Let the system include the block, the putty, and Earth. Then $F_{ext,net}$ = 0 and momentum is conserved in this perfectly inelastic collision. We'll use conservation of momentum to relate the after-collision velocity of the block plus blob and conservation of energy to find their after-collision velocity.

Noting that, because this is a perfectly elastic collision, the final velocity of the block plus blob is the velocity of the center of mass, use conservation of momentum to relate the velocity of the center of mass to the velocity of the glob before the collision:

$$p_i=p_f$$

or

$$m_{gl}v_{gl}=Mv_{cm}\Rightarrow v_{gl}=\left(\frac{M}{m_{gl}}\right)v_{cm}\quad(1)$$

where $M=m_{gl}+m_{bl}$.

Use conservation of energy to find the initial energy of the block plus glob:

$$\Delta K+\Delta U+W_f=0$$

Because $\Delta U=K_f=0$,

$$-\tfrac{1}{2}Mv_{cm}^2+f_k\Delta x=0$$

Because $f_k=\mu_k Mg$:

$$-\tfrac{1}{2}Mv_{cm}^2+\mu_k Mg\Delta x=0$$

Solve for v_{cm} to obtain:

$$v_{cm}=\sqrt{2\mu_k g\Delta x}$$

Substitute numerical values and evaluate v_{cm}:

$$v_{cm}=\sqrt{2(0.40)(9.81\,\text{m/s}^2)(0.15\,\text{m})}=1.08\,\text{m/s}$$

Substitute numerical values in equation (1) and evaluate v_{gl}:

$$v_{gl} = \left(\frac{13\,\text{kg} + 0.400\,\text{kg}}{0.400\,\text{kg}}\right)(1.08\,\text{m/s}) = \boxed{36\,\text{m/s}}$$

109 ••• [SSM] Your accident reconstruction team has been hired by the local police to analyze the following accident. A careless driver rear-ended a car that was halted at a stop sign. Just before impact, the driver slammed on his brakes, locking the wheels. The driver of the struck car had his foot solidly on the brake pedal, locking his brakes. The mass of the struck car was 900 kg, and that of the initially moving vehicle was 1200 kg. On collision, the bumpers of the two cars meshed. Police determine from the skid marks that after the collision the two cars moved 0.76 m together. Tests revealed that the coefficient of kinetic friction between the tires and pavement was 0.92. The driver of the moving car claims that he was traveling at less than 15 km/h as he approached the intersection. Is he telling the truth?

Picture the Problem Let the direction the moving car was traveling before the collision be the +*x* direction. Let the numeral 1 denote this car and the numeral 2 the car that is stopped at the stop sign and the system include both cars and Earth. We can use conservation of momentum to relate the speed of the initially-moving car to the speed of the meshed cars immediately after their perfectly inelastic collision and conservation of energy to find the initial speed of the meshed cars.

Using conservation of momentum, relate the before-collision speed to the after-collision speed of the meshed cars:

$$p_i = p_f$$

or

$$m_1v_1 = (m_1 + m_2)V$$

Solving for v_1 and simplifying yields:

$$v_1 = \frac{m_1 + m_2}{m_1}V = \left(1 + \frac{m_2}{m_1}\right)V \qquad (1)$$

Using conservation of energy, relate the initial kinetic energy of the meshed cars to the work done by friction in bringing them to a stop:

$$\Delta K + \Delta E_{\text{thermal}} = 0$$

or, because $K_f = 0$ and $\Delta E_{\text{thermal}} = f\Delta s$,

$$-K_i + f_k\Delta s = 0$$

Substitute for K_i and, using $f_k = \mu_k F_n = \mu_k Mg$, eliminate f_k to obtain:

$$-\tfrac{1}{2}MV^2 + \mu_k Mg\Delta x = 0$$

Solving for V yields:

$$V = \sqrt{2\mu_k g\Delta x}$$

Substitute for V in equation (1) to obtain:

$$v_1 = \left(1 + \frac{m_2}{m_1}\right)\sqrt{2\mu_k g\Delta x}$$

Substitute numerical values and evaluate v_1:

$$v_1 = \left(1 + \frac{900\,\text{kg}}{1200\,\text{kg}}\right)\sqrt{2(0.92)(9.81\,\text{m/s}^2)(0.76\,\text{m})} = 6.48\,\text{m/s} = 23\,\text{km/h}$$

The driver was not telling the truth. He was traveling at 23 km/h.

110 •• A pendulum consists of a compact 0.40-kg bob attached to a string of length 1.6 m. A block of mass *m* rests on a horizontal frictionless surface. The pendulum is released from rest at an angle of 53º with the vertical. The bob collides elastically with the block at the lowest point in its arc. Following the collision, the maximum angle of the pendulum with the vertical is 5.73º. Determine the mass *m*.

Picture the Problem Let the zero of gravitational potential energy be at the lowest point of the bob's swing and note that the bob can swing either forward or backward after the collision. We'll use both conservation of momentum and conservation of energy to relate the velocities of the bob and the block before and after their collision. Choose the $+x$ direction to be in the direction of the motion of the block.

Express the kinetic energy of the block in terms of its after-collision momentum:

$$K_\text{m} = \frac{p_m^2}{2m} \Rightarrow m = \frac{p_m^2}{2K_m} \qquad (1)$$

Use conservation of energy to relate K_m to the change in the potential energy of the bob:

$$\Delta K + \Delta U = 0$$

or, because $K_\text{i} = 0$,

$$K_m + U_\text{f} - U_\text{i} = 0$$

Solve for K_m, substitute for U_f and U_i and simplify to obtain:

$$\begin{aligned} K_m &= -U_\text{f} + U_\text{i} \\ &= m_\text{bob} g\left[L(1-\cos\theta_\text{i}) - L(1-\cos\theta_\text{f})\right] \\ &= m_\text{bob} gL\left[\cos\theta_\text{f} - \cos\theta_\text{i}\right] \end{aligned}$$

Substitute numerical values and evaluate K_m:

$$K_m = (0.40\,\text{kg})(9.81\,\text{m/s}^2)(1.6\,\text{m})[\cos 5.73° - \cos 53°] = 2.47\,\text{J}$$

Use conservation of energy to find the velocity of the bob just before its collision with the block:	$\Delta K + \Delta U = 0$ or, because $K_i = U_f = 0$, $K_f - U_i = 0$
Substitute for K_f and U_i to obtain:	$\frac{1}{2} m_{bob} v^2 - m_{bob} gL(1-\cos\theta_i) = 0$
Solving for v yields:	$v = \sqrt{2gL(1-\cos\theta_i)}$
Substitute numerical values and evaluate v:	$v = \sqrt{2(9.81\,\text{m/s}^2)(1.6\,\text{m})(1-\cos 53°)} = 3.536\,\text{m/s}$
Use conservation of energy to find the velocity of the bob just after its collision with the block:	$\Delta K + \Delta U = 0$ or, because $K_f = U_i = 0$, $-K_i + U_f = 0$
Substitute for K_i and U_f to obtain:	$-\frac{1}{2} m_{bob} v'^2 + m_{bob} gL(1-\cos\theta_f) = 0$
Solve for v':	$v' = \sqrt{2gL(1-\cos\theta_f)}$
Substitute numerical values and evaluate v':	$v' = \sqrt{2(9.81\,\text{m/s}^2)(1.6\,\text{m})(1-\cos 5.73°)} = 0.396\,\text{m/s}$
Use conservation of momentum to relate p_m after the collision to the momentum of the bob just before and just after the collision:	$p_i = p_f$ or $m_{bob} v = \pm m_{bob} v' + p_m$
Solve for and evaluate p_m:	$p_m = m_{bob} v \pm m_{bob} v' = (0.40\,\text{kg})(3.536\,\text{m/s} \pm 0.396\,\text{m/s}) = 1.414\,\text{kg}\cdot\text{m/s} \pm 0.158\,\text{kg}\cdot\text{m/s}$
Find the larger value for p_m:	$p_m = 1.414\,\text{kg}\cdot\text{m/s} + 0.158\,\text{kg}\cdot\text{m/s} = 1.573\,\text{kg}\cdot\text{m/s}$
Find the smaller value for p_m:	$p_m = 1.414\,\text{kg}\cdot\text{m/s} - 0.158\,\text{kg}\cdot\text{m/s} = 1.256\,\text{kg}\cdot\text{m/s}$

Substitute numerical values in equation (1) to determine the two values for m:

$$m = \frac{(1.573\,\text{kg}\cdot\text{m/s})^2}{2(2.47\,\text{J})} = \boxed{0.50\,\text{kg}}$$

or

$$m = \frac{(1.256\,\text{kg}\cdot\text{m/s})^2}{2(2.47\,\text{J})} = \boxed{0.32\,\text{kg}}$$

111 ••• [SSM] A 1.00-kg block and a second block of mass M are both initially at rest on a frictionless inclined plane (Figure 8-56) Mass M rests against a spring that has a force constant of 11.0 kN/m. The distance along the plane between the two blocks is 4.00 m. The 1.00-kg block is released, making an elastic collision with the unknown block. The 1.00-kg block then rebounds a distance of 2.56 m back up the inclined plane. The block of mass M comes momentarily comes to rest 4.00 cm from its initial position. Find M.

Picture the Problem Choose the zero of gravitational potential energy at the location of the spring's maximum compression. Let the system include the spring, the blocks, and Earth. Then the net external force is zero as is work done against friction. We can use conservation of energy to relate the energy transformations taking place during the evolution of this system.

Apply conservation of energy to the system:

$$\Delta K + \Delta U_g + \Delta U_s = 0$$

Because $\Delta K = 0$:

$$\Delta U_g + \Delta U_s = 0$$

Express the change in the gravitational potential energy:

$$\Delta U_g = -mg\Delta h - Mgx\sin\theta$$

Express the change in the potential energy of the spring:

$$\Delta U_s = \tfrac{1}{2}kx^2$$

Substitute to obtain:

$$-mg\Delta h - Mgx\sin\theta + \tfrac{1}{2}kx^2 = 0$$

Solving for M and simplifying yields:

$$M = \frac{\tfrac{1}{2}kx^2 - mg\Delta h}{gx\sin 30°} = \frac{kx}{g} - \frac{2m\Delta h}{x}$$

Relate Δh to the initial and rebound positions of the block whose mass is m:

$$\Delta h = (4.00\,\text{m} - 2.56\,\text{m})\sin 30° = 0.72\,\text{m}$$

Substitute numerical values and evaluate M:

$$M = \frac{\left(11.0\times10^{3}\ \text{N/m}\right)\left(0.0400\,\text{m}\right)}{9.81\,\text{m/s}^2} - \frac{2\left(1.00\,\text{kg}\right)\left(0.72\,\text{m}\right)}{0.0400\,\text{m}} = \boxed{8.9\,\text{kg}}$$

112 ••• A neutron of mass m makes an elastic head-on collision with a stationary nucleus of mass M. (*a*) Show that the kinetic energy of the nucleus after the collision is given by $K_{\text{nucleus}} = [4mM/(m + M)^2]K_{\text{n}}$, where K_{n} is the initial kinetic energy of the neutron. (*b*) Show that the *fractional* change in the kinetic energy of the neutron is given by

$$\frac{\Delta K_{\text{n}}}{K_{\text{n}}} = -\frac{4(m/M)}{\left(1+[m/M]\right)^2}\,.$$

(*c*) Show that this expression gives plausible results both if $m << M$ and $m = M$. What is the best stationary nucleus for the neutron to collide head-on with if the objective is to produce a maximum loss in the kinetic energy of the neutron?

Picture the Problem In this elastic head-on collision, the kinetic energy of recoiling nucleus is the difference between the initial and final kinetic energies of the neutron. We can derive the indicated results by using both conservation of energy and conservation of momentum and writing the kinetic energies in terms of the momenta of the particles before and after the collision.

(*a*) Use conservation of energy to relate the kinetic energies of the particles before and after the collision:

$$\frac{p_{\text{ni}}^2}{2m} = \frac{p_{\text{nf}}^2}{2m} + \frac{p_{\text{nucleus}}^2}{2M} \qquad (1)$$

Apply conservation of momentum to obtain a second relationship between the initial and final momenta:

$$p_{\text{ni}} = p_{\text{nf}} + p_{\text{nucleus}} \qquad (2)$$

Eliminate p_{nf} in equation (1) using equation (2):

$$\frac{p_{\text{nucleus}}}{2M} + \frac{p_{\text{nucleus}}}{2m} - \frac{p_{\text{ni}}}{m} = 0 \qquad (3)$$

Use equation (3) to write $p_{\text{ni}}^2/2m$ in terms of p_{nucleus}:

$$\frac{p_{\text{ni}}^2}{2m} = K_{\text{n}} = \frac{p_{\text{nucleus}}^2\left(M+m\right)^2}{8M^2m} \qquad (4)$$

Use equation (4) to express $K_{\text{nucleus}} = p_{\text{nucleus}}^2/2M$ in terms of K_{n}:

$$K_{\text{nucleus}} = \boxed{K_{\text{n}}\left[\frac{4Mm}{\left(M+m\right)^2}\right]} \qquad (5)$$

(*b*) Relate the *change* in the kinetic energy of the neutron to the after-collision kinetic energy of the nucleus:

$$\Delta K_{\text{n}} = -K_{\text{nucleus}}$$

Using equation (5), express the fraction of the energy lost in the collision:

$$\frac{\Delta K_{\text{n}}}{K_{\text{n}}} = -\frac{4Mm}{(M+m)^2} = \boxed{-\frac{4(m/M)}{(1+(m/M))^2}}$$

(*c*) If $m << M$:

$$\frac{\Delta K_{\text{n}}}{K_{\text{n}}} \to \boxed{0} \text{ as expected.}$$

If $m = M$:

$$\frac{\Delta K_{\text{n}}}{K_{\text{n}}} = -\frac{4}{(1+1)^2} = \boxed{-1} \text{ as expected.}$$

113 ••• The mass of a carbon nucleus is approximately 12 times the mass of a neutron. (*a*) Use the results of Problem 112 to show that after *N* head-on collisions of a neutron with carbon nuclei at rest, the kinetic energy of the neutron is approximately $0.716^N K_0$, where K_0 is its initial kinetic energy. (*b*) Neutrons emitted during the fission of a uranium nucleus have kinetic energies of about 2.0 MeV. For such a neutron to cause the fission of another uranium nucleus in a reactor, its kinetic energy must be reduced to about 0.020 eV. How many head-on collisions are needed to reduce the kinetic energy of a neutron from 2.0 MeV to 0.020 eV, assuming elastic head-on collisions with stationary carbon nuclei?

Picture the Problem Problem 112 (*b*) provides an expression for the fractional loss of kinetic energy per collision.

(*a*) Using the result of Problem 112 (*b*), express the fractional loss of energy per collision:

$$\frac{K_{\text{nf}}}{K_{\text{ni}}} = \frac{K_{\text{ni}} - \Delta K_{\text{n}}}{E_0} = \frac{(M-m)^2}{(M+m)^2}$$

Evaluate this fraction to obtain:

$$\frac{K_{\text{nf}}}{E_0} = \frac{(12m-m)^2}{(12m+m)^2} = 0.716$$

Express the kinetic energy of one neutron after *N* collisions:

$$K_{\text{nf}} = \boxed{0.716^N E_0}$$

(*b*) Substitute for K_{nf} and E_0 to obtain:

$$0.716^N = 10^{-8}$$

Take the logarithm of both sides of the equation and solve for N:

$$N = \frac{-8}{\log 0.716} \approx \boxed{55}$$

114 ••• On average, a neutron actually loses only 63 percent of its energy in an elastic collision with a hydrogen atom (not 100 percent) and 11 percent of its energy during an elastic collision with a carbon atom (not 28 percent). (These numbers are an average over all types of collisions, not just head-on ones. Thus the results are lower than the ones determined from analyses like that in Problem 113 because most collisions are not head-on.) Calculate the actual number of collisions, on average, needed to reduce the energy of a neutron from 2.0 MeV to 0.020 eV if the neutron collides with stationary (*a*) hydrogen atoms and (*b*) carbon atoms.

Picture the Problem We can relate the number of collisions needed to reduce the energy of a neutron from 2 MeV to 0.02 eV to the fractional energy loss per collision and solve the resulting exponential equation for N.

(*a*) Using the result of Problem 113 (*b*), express the fractional loss of energy per collision:

$$\frac{K_{\text{nf}}}{K_{\text{ni}}} = \frac{K_{\text{ni}} - \Delta K_{\text{n}}}{E_0} = \frac{K_{\text{ni}} - 0.63K_{\text{ni}}}{K_{\text{ni}}} = 0.37$$

Express the kinetic energy of one neutron after N collisions:

$$K_{\text{nf}} = 0.37^N K_0$$

Substitute for K_{nf} and K_0 to obtain:

$$0.37^N = 10^{-8}$$

Take the logarithm of both sides of the equation and solve for N:

$$N = \frac{-8}{\log 0.37} \approx \boxed{19}$$

(*b*) Proceed as in (*a*) to obtain:

$$\frac{K_{\text{nf}}}{K_{\text{ni}}} = \frac{K_{\text{ni}} - \Delta K_{\text{n}}}{E_0} = \frac{K_{\text{ni}} - 0.11K_{\text{ni}}}{K_{\text{ni}}} = 0.89$$

Express the kinetic energy of one neutron after N collisions:

$$K_{\text{nf}} = 0.89^N K_0$$

Substitute for K_{nf} and K_0 to obtain:

$$0.89^N = 10^{-8}$$

Take the logarithm of both sides of the equation and solve for N:

$$N = \frac{-8}{\log 0.89} \approx \boxed{158}$$

115 ••• **[SSM]** Two astronauts at rest face each other in space. One, with mass m_1, throws a ball of mass m_b to the other, whose mass is m_2. She catches the ball and throws it back to the first astronaut. Following each throw the ball has a speed of v relative to the thrower. After each has made one throw and one catch, (*a*) How fast are the astronauts moving? (*b*) How much has the two-astronaut system's kinetic energy changed and where did this energy come from?

Picture the Problem Let the direction that astronaut 1 first throws the ball be the positive direction and let v_b be the initial speed of the ball in the laboratory frame. Note that each collision is perfectly inelastic. We can apply conservation of momentum and the definition of the speed of the ball relative to the thrower to each of the perfectly inelastic collisions to express the final speeds of each astronaut after one throw and one catch.

(*a*) Use conservation of linear momentum to relate the speeds of astronaut 1 and the ball after the first throw:

$$m_1v_1 + m_bv_b = 0 \tag{1}$$

Relate the speed of the ball in the laboratory frame to its speed relative to astronaut 1:

$$v = v_b - v_1 \tag{2}$$

Eliminate v_b between equations (1) and (2) and solve for v_1:

$$v_1 = -\frac{m_b}{m_1 + m_b}v \tag{3}$$

Substitute equation (3) in equation (2) and solve for v_b:

$$v_b = \frac{m_1}{m_1 + m_b}v \tag{4}$$

Apply conservation of linear momentum to express the speed of astronaut 2 and the ball after the first catch:

$$0 = m_bv_b = (m_2 + m_b)v_2 \tag{5}$$

Solving for v_2 yields:

$$v_2 = \frac{m_b}{m_2 + m_b}v_b \tag{6}$$

Express v_2 in terms of v by substituting equation (4) in equation (6):

$$\begin{aligned} v_2 &= \frac{m_b}{m_2 + m_b}\frac{m_1}{m_1 + m_b}v \\ &= \left[\frac{m_bm_1}{(m_2 + m_b)(m_1 + m_b)}\right]v \end{aligned} \tag{7}$$

Use conservation of momentum to express the speed of astronaut 2 and the ball after she throws the ball:

$$(m_2 + m_b)v_2 = m_b v_{bf} + m_2 v_{2f} \qquad (8)$$

Relate the speed of the ball in the laboratory frame to its speed relative to astronaut 2:

$$v = v_{2f} - v_{bf} \qquad (9)$$

Eliminate v_{bf} between equations (8) and (9) and solve for v_{2f}:

$$v_{2f} = \boxed{\left(\frac{m_b}{m_2 + m_b}\right)\left(1 + \frac{m_1}{m_1 + m_b}\right)v} \qquad (10)$$

Substitute equation (10) in equation (9) and solve for v_{bf}:

$$v_{bf} = \left[\frac{m_b}{m_2 + m_b} - 1\right]\left[1 + \frac{m_1}{m_1 + m_b}\right]v \qquad (11)$$

Apply conservation of momentum to express the speed of astronaut 1 and the ball after she catches the ball:

$$(m_1 + m_b)v_{1f} = m_b v_{bf} + m_1 v_1 \qquad (12)$$

Using equations (3) and (11), eliminate v_{bf} and v_1 in equation (12) and solve for v_{1f}:

$$v_{1f} = \boxed{-\frac{m_2 m_b (2m_1 + m_b)}{(m_1 + m_b)^2 (m_2 + m_b)} v}$$

(*b*) The change in the kinetic energy of the system is:

$$\Delta K = K_f - K_i$$

or, because $K_i = 0$,

$$\Delta K = K_f = K_{1f} + K_{2f} = \tfrac{1}{2} m_1 v_{1f}^2 + \tfrac{1}{2} m_2 v_{2f}^2$$

Substitute for v_{1f} and v_{2f} to obtain:

$$\Delta K = \tfrac{1}{2} m_1 \left(-\frac{m_2 m_b (2m_1 + m_b)}{(m_1 + m_b)^2 (m_2 + m_b)}\right)^2 v^2 + \tfrac{1}{2} m_2 \left(\frac{m_b}{m_2 + m_b}\right)^2 \left(1 + \frac{m_1}{m_1 + m_b}\right)^2 v^2$$

Simplify to obtain:

$$\Delta K = \boxed{\tfrac{1}{2} \frac{m_2 m_b^2 (2m_1 + m_b)^2}{(m_2 + m_b)^2 (m_1 + m_b)^2} \left(1 + \frac{m_1 m_2}{(m_1 + m_b)^2}\right) v^2}$$

This additional energy came from chemical energy in the astronaut’s bodies.

116 ••• A stream of elastic glass beads, each with a mass of 0.50 g, comes out of a horizontal tube at a rate of 100 per second (see Figure 8-57). The beads fall a distance of 0.50 m to a balance pan and bounce back to their original height. How much mass must be placed in the other pan of the balance to keep the pointer at zero?

Picture the Problem Take the zero of gravitational potential energy to be at the elevation of the pan and let the system include the balance, the beads, and Earth. We can use conservation of energy to find the vertical component of the velocity of the beads as they hit the pan and then calculate the net downward force on the pan from Newton's second law. Let the +*y* direction be upward.

Use conservation of energy to relate the *y* component of the bead's velocity as it hits the pan to its height of fall:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$\tfrac{1}{2}mv_y^2 - mgh = 0 \Rightarrow v_y = \sqrt{2gh}$$

Substitute numerical values and evaluate v_y:

$$v_y = \sqrt{2\left(9.81\,\text{m/s}^2\right)\left(0.50\,\text{m}\right)} = 3.13\,\text{m/s}$$

Express the change in momentum in the *y* direction per bead:

$$\Delta p_y = p_{yf} - p_{yi} = mv_y - \left(-mv_y\right) = 2mv_y$$

Use Newton's second law to express the net force in the *y* direction exerted on the pan by the beads:

$$F_{\text{net},y} = -N\frac{\Delta p_y}{\Delta t}$$

Letting *M* represent the mass to be placed on the other pan, equate its weight to the net force exerted by the beads, substitute for Δp_y, and solve for *M*:

$$-Mg = -N\frac{\Delta p_y}{\Delta t}$$

and

$$M = \frac{N}{\Delta t}\left(\frac{2mv_y}{g}\right)$$

Substitute numerical values and evaluate *M*:

$$M = \left(100/\text{s}\right)\frac{\left[2\left(0.00050\,\text{kg}\right)\left(3.13\,\text{m/s}\right)\right]}{9.81\,\text{m/s}^2} = \boxed{32\,\text{g}}$$

117 ••• A dumbbell, consisting of two balls of mass *m* connected by a massless 1.00-m-long rod, rests on a frictionless floor against a frictionless wall with one ball directly above the other. The center-to-center distance between the balls is equal to 1.00. The dumbbell then begins to slide down the wall as in Figure 8-58. Find the speed of the bottom ball at the moment when it equals the speed of the top ball.

Picture the Problem Assume that the connecting rod goes halfway through both balls, i.e., the centers of mass of the balls are separated by 1.00 m. Let the system include the dumbbell, the wall and floor, and Earth. Let the zero of gravitational potential be at the center of mass of the lower ball and use conservation of energy to relate the speeds of the balls to the potential energy of the system. By symmetry, the speeds will be equal when the angle with the vertical is 45°.

Use conservation of energy to express the relationship between the initial and final energies of the system:

$$E_i = E_f$$

Express the initial energy of the system:

$$E_i = mgL$$

where L is the length of the rod.

Express the energy of the system when the angle with the vertical is 45°:

$$E_f = mgL\sin 45° + \tfrac{1}{2}(2m)v^2$$

Substitute to obtain:

$$gL = gL\left(\frac{1}{\sqrt{2}}\right) + v^2$$

Solving for v yields:

$$v = \sqrt{gL\left(1 - \frac{1}{\sqrt{2}}\right)}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(9.81\,\text{m/s}^2)(1.00\,\text{m})\left(1 - \frac{1}{\sqrt{2}}\right)}$$

$$= \boxed{1.70\ \text{m/s}}$$

Chapter 9
Rotation

Conceptual Problems

1 • Two points are on a disk that is turning about a fixed-axis through its center, perpendicular to the disk and through its center, at increasing angular velocity. One point is on the rim and the other point is halfway between the rim and the center. (*a*) Which point moves the greater distance in a given time? (*b*) Which point turns through the greater angle? (*c*) Which point has the greater speed? (*d*) Which point has the greater angular speed? (*e*) Which point has the greater tangential acceleration? (*f*) Which point has the greater angular acceleration? (*g*) Which point has the greater centripetal acceleration?

Determine the Concept (*a*) Because r is greater for the point on the rim, it moves the greater distance. (*b*) Both points turn through the same angle. (*c*) Because r is greater for the point on the rim, it has the greater speed. (*d*) Both points have the same angular speed. (*e*) Both points have zero tangential acceleration. (*f*) Both have zero angular acceleration. (*g*) Because r is greater for the point on the rim, it has the greater centripetal acceleration.

2 • True or false:

(*a*) Angular speed and linear speed have the same dimensions.
(*b*) All parts of a wheel rotating about a fixed axis must have the same angular speed.
(*c*) All parts of a wheel rotating about a fixed axis must have the same angular acceleration.
(*d*) All parts of a wheel rotating about a fixed axis must have the same centripetal acceleration.

(*a*) False. Angular speed has the dimensions $\left[1/\mathrm{T}\right]$whereas linear speed has dimensions$\left[\mathrm{L}/\mathrm{T}\right]$.

(*b*) True. The angular speed of all points on a wheel is $d\theta/dt$.

(*c*) True. The angular acceleration of all points on the wheel is $d\omega/dt$.

(*d*) False. The centripetal acceleration at a point on a rotating wheel is directly proportional to its distance from the center of the wheel

3 • Starting from rest and rotating at constant angular acceleration, a disk takes 10 revolutions to reach an angular speed ω. How many additional revolutions at the same angular acceleration are required for it to reach an angular speed of 2ω? (*a*) 10 rev, (*b*) 20 rev, (*c*) 30 rev, (*d*) 40 rev, (*e*) 50 rev?

Picture the Problem The constant-acceleration equation that relates the given variables is $\omega^2 = \omega_0^2 + 2\alpha\Delta\theta$. We can set up a proportion to determine the number of revolutions required to double ω and then subtract to find the number of additional revolutions to accelerate the disk to an angular speed of 2ω.

Using a constant-acceleration equation, relate the initial and final angular velocities to the angular acceleration:

$$\omega^2 = \omega_0^2 + 2\alpha\Delta\theta$$

or, because $\omega_0^2 = 0$,

$$\omega^2 = 2\alpha\Delta\theta$$

Let $\Delta\theta_{10}$ represent the number of revolutions required to reach an angular speed ω:

$$\omega^2 = 2\alpha\Delta\theta_{10} \qquad (1)$$

Let $\Delta\theta_{2\omega}$ represent the number of revolutions required to reach an angular speed ω:

$$(2\omega)^2 = 2\alpha\Delta\theta_{2\omega} \qquad (2)$$

Divide equation (2) by equation (1) and solve for $\Delta\theta_{2\omega}$:

$$\Delta\theta_{2\omega} = \frac{(2\omega)^2}{\omega^2}\Delta\theta_{10} = 4\Delta\theta_{10}$$

The number of *additional* revolutions is:

$$4\Delta\theta_{10} - \Delta\theta_{10} = 3\Delta\theta_{10} = 3(10\,\text{rev}) = 30\,\text{rev}$$

and $\boxed{(c)}$ is correct.

4 • You are looking down from above at a merry-go-round, and observe that is rotating counterclockwise and its rotation rate is slowing. If we designate counterclockwise as positive, what is the sign of the angular acceleration?

Determine the Concept Because the merry-go-round is slowing, the sign of its angular acceleration is $\boxed{\text{negative.}}$

5 • Chad and Tara go for a ride on a merry-go-round. Chad sits on a pony that is 2.0 m from the rotation axis, and Tara sits on a pony 4.0 m from the axis. The merry-go-round is traveling counterclockwise and is speeding up. Does Chad or Tara have (*a*) the larger linear speed? (*b*) the larger centripetal acceleration? (*c*) the larger tangential acceleration?

Determine the Concept

(*a*) The linear speed of all points on the merry-go-round is given by $v = r\omega$. Because she is farther from the rotation axis, Tara has the larger linear speed.

(*b*) The centripetal acceleration of all points on the merry-go-round is given by $a_c = r\omega^2$. Because she is farther from the rotation axis, Tara has the larger centripetal acceleration.

(*c*) The tangential acceleration of all points on the merry-go-round is given by $a_t = r\alpha$. Because the angular acceleration is the same for all points on the merry-go-round and she is farther from the rotation axis, Tara has the larger tangential acceleration.

6 • Disk B was identical to disk A before a hole was drilled though the center of disk B. Which disk has the largest moment of inertia about its symmetry axis center? Explain your answer.

Determine the Concept Because its mass is now greater than that of disk B, disk $\boxed{\text{A}}$ has the larger moment of inertia about its axis of symmetry.

7 • **[SSM]** The pitcher in a baseball game has a blazing fastball. You have not been able to swing the bat in time to hit the ball. You are now just trying to make the bat connect with the ball, hit the ball foul, and avoid a strikeout. So you decide to take your coach's advice and grip the bat high rather than at the very end. This change should increase bat speed; thus, you will be able to swing the bat quicker and increase your chances of hitting the ball. Explain how this theory works in terms of the moment of inertia, angular acceleration, and torque of the bat.

Determine the Concept By choking up, you are rotating the bat about an axis closer to the center of mass, thus reducing the bat's moment of inertia. The smaller the moment of inertia the larger the angular acceleration (a quicker bat) for the same torque.

8 • (*a*) Is the direction of an object's angular velocity necessarily the same as the direction of the net torque on it? Explain. (*b*) If the net torque and angular velocity are in opposite directions, what does that tell you about the angular speed? (*c*) Can the angular velocity be zero even if the net torque is not zero? If your answer is yes, give an example.

(*a*) No. If the object is slowing down, they are oppositely directed.

(*b*) The angular speed of the object will decrease.

(*c*) Yes. At the instant the object is stopping and turning around (angularly), such as a pendulum at its turnaround (highest) point, the net torque is not zero and the angular velocity is zero.

9 • A disk is free to rotate about a fixed axis. A tangential force applied a distance d from the axis causes an angular acceleration α. What angular acceleration is produced if the same force is applied a distance $2d$ from the axis? (*a*) α, (*b*) 2α, (*c*) $\alpha/2$, (*d*) 4α, (*e*) $\alpha/4$?

Determine the Concept The angular acceleration of a rotating object is proportional to the *net* torque acting on it. The net torque is the product of the tangential force and its lever arm.

Express the angular acceleration of the disk as a function of the net torque acting on it:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{Fd}{I} = \frac{F}{I}d \Rightarrow \alpha \propto d$$

Because $\alpha \propto d$, doubling d will double the angular acceleration. $\boxed{(b)}$ is correct.

10 • The moment of inertia of an object about an axis that does not pass through its center of mass is ______ the moment of inertia about a parallel axis through its center of mass. (*a*) always less than, (*b*) sometimes less than, (*c*) sometimes equal to, (*d*) always greater than.

Determine the Concept From the parallel-axis theorem we know that $I = I_{\text{cm}} + Mh^2$, where I_{cm} is the moment of inertia of the object with respect to an axis through its center of mass, M is the mass of the object, and h is the distance between the parallel axes. Therefore, I is always greater than I_{cm} by Mh^2. $\boxed{(d)}$ is correct.

11 • **[SSM]** The motor of a merry-go-round exerts a constant torque on it. As it speeds up from rest, the power output of the motor (*a*) is constant, (*b*) increases linearly with the angular speed of the merry-go-round, (*c*) is zero. (*d*) None of the above.

Determine the Concept The power delivered by the constant torque is the product of the torque and the angular speed of the merry-go-round. Because the constant torque causes the merry-go-round to accelerate, the power output increases linearly with the angular speed of the merry-go-round. $\boxed{(b)}$ is correct.

12 • A constant net torque acts on a merry-go-round from startup until it reaches its operating speed. During this time, the merry-go-round's rotational kinetic energy (*a*) is constant, (*b*) increases linearly with angular speed, (*c*) increases quadratically as the square of the angular speed, (*d*) none of the above.

Determine the Concept The work done by the net torque increases the rotational kinetic energy of the merry-go-round. Because $K_{\text{rot}} = \frac{1}{2}I\omega^2$, $\boxed{(c)}$ is correct.

13 • Most doors knobs are designed so the knob is located on the side opposite the hinges (rather than in the center of the door, for example). Explain why this practice makes doors easier to open.

Determine the Concept One reason is to maximize the moment arm about the line through the hinge pins for the force exerted by someone pulling or pushing on the knob.

14 • A wheel of radius R and angular speed ω is rolling without slipping toward the north on a flat, stationary surface. The velocity of the point on the rim that is (momentarily) in contact with the surface is (*a*) equal in magnitude to $R\omega$ and directed toward the north, (*b*) equal to in magnitude $R\omega$ and directed toward the south, (*c*) zero, (*d*) equal to the speed of the center of mass and directed toward the north, (*e*) equal to the speed of the center of mass and directed toward the south.

Determine the Concept If the wheel is rolling without slipping, a point at the top of the wheel moves with a speed twice that of the center of mass of the wheel, but the bottom of the wheel is momentarily at rest. $\boxed{(c)}$ is correct.

15 • A uniform solid cylinder and a uniform solid sphere have equal masses. Both roll without slipping on a horizontal surface without slipping. If their total kinetic energies are the same, then (*a*) the translational speed of the cylinder is greater than the translational speed of the sphere, (*b*) the translational speed of the cylinder is less than the translational speed of the sphere, (*c*) the translational speeds of the two objects are the same, (*d*) (*a*), (*b*), or (*c*) could be correct depending on the radii of the objects.

Picture the Problem The kinetic energies of both objects is the sum of their translational and rotational kinetic energies. Their speed dependence will differ due to the differences in their moments of inertia. We can express the total kinetic energy of both objects and equate them to decide which of their translational speeds is greater.

Express the kinetic energy of the cylinder:

$$\begin{aligned} K_{\text{cyl}} &= \tfrac{1}{2}I_{\text{cyl}}\omega_{\text{cyl}}^2 + \tfrac{1}{2}mv_{\text{cyl}}^2 \\ &= \tfrac{1}{2}\left(\tfrac{1}{2}mr^2\right)\frac{v_{\text{cyl}}^2}{r^2} + \tfrac{1}{2}mv_{\text{cyl}}^2 \\ &= \tfrac{3}{4}mv_{\text{cyl}}^2 \end{aligned}$$

Express the kinetic energy of the sphere:

$$K_{\text{sph}} = \tfrac{1}{2} I_{\text{sph}} \omega_{\text{sphl}}^2 + \tfrac{1}{2} m v_{\text{sph}}^2 = \tfrac{1}{2}\left(\tfrac{2}{5} m r^2\right)\frac{v_{\text{sph}}^2}{r^2} + \tfrac{1}{2} m v_{\text{sph}}^2 = \tfrac{7}{10} m v_{\text{sph}}^2$$

Equate the kinetic energies and simplify to obtain:

$v_{\text{cyl}} = \sqrt{\tfrac{14}{15}}\, v_{\text{sph}} < v_{\text{sph}}$ and $\boxed{(b)}$ is correct.

16 • Two identical-looking 1.0-m-long pipes are each plugged with 10 kg of lead. In the first pipe, the lead is concentrated at the middle of the pipe, while in the second the lead is divided into two 5-kg masses placed at opposite ends of the pipe. The ends of the pipes are then sealed using four identical caps. Without opening either pipe, how could you determine which pipe has the lead at both ends?

Determine the Concept You could spin the pipes about their center. The one which is easier to spin has its mass concentrated closer to the center of mass and, hence, has a smaller moment of inertia.

17 •• Starting simultaneously from rest, a coin and a hoop roll without slipping down an incline. Which of the following statements is true? (*a*) The hoop reaches the bottom first. (*b*) The coin reaches the bottom first. (*c*) The coin and hoop arrive at the bottom simultaneously. (*d*) The race to the bottom depends on their relative masses. (*e*) The race to the bottom depends on their relative diameters.

Picture the Problem The object moving the fastest when it reaches the bottom of the incline will arrive there first. Because the coin and the hoop begin from the same elevation, they will have the same kinetic energy at the bottom of the incline. The kinetic energies of both objects is the sum of their translational and rotational kinetic energies. Their speed dependence will differ due to the differences in their moments of inertia. We can express the total kinetic of both objects and equate them to their common potential energy loss to decide which of their translational speeds is greater at the bottom of the incline.

Express the kinetic energy of the coin at the bottom of the incline:

$$K_{\text{coin}} = \tfrac{1}{2} I_{\text{cyl}} \omega_{\text{coin}}^2 + \tfrac{1}{2} m_{\text{coin}} v_{\text{coin}}^2 = \tfrac{1}{2}\left(\tfrac{1}{2} m_{\text{coin}} r^2\right)\frac{v_{\text{coin}}^2}{r^2} + \tfrac{1}{2} m_{\text{coin}} v_{\text{coin}}^2 = \tfrac{3}{4} m_{\text{coin}} v_{\text{coin}}^2$$

Express the kinetic energy of the hoop at the bottom of the incline:

$$K_{\text{hoop}} = \tfrac{1}{2} I_{\text{hoop}} \omega_{\text{hoop}}^2 + \tfrac{1}{2} m_{\text{hoop}} v_{\text{hoop}}^2 = \tfrac{1}{2}\left(m_{\text{hoop}} r^2\right)\frac{v_{\text{hoop}}^2}{r^2} + \tfrac{1}{2} m_{\text{hoop}} v_{\text{hoop}}^2 = m_{\text{hoop}} v_{\text{hoop}}^2$$

Equate the kinetic energy of the coin to its change in potential energy as it rolled down the incline and solve for v_{coin}:

$$\tfrac{3}{4} m_{\text{coin}} v_{\text{coin}}^2 = m_{\text{coin}} gh \Rightarrow v_{\text{coin}} = \sqrt{\tfrac{4}{3} gh}$$

Equate the kinetic energy of the hoop to its change in potential energy as it rolled down the incline and solve for v_{hoop}:

$$m_{\text{hoop}} v_{\text{hoop}}^2 = m_{\text{hoop}} gh \Rightarrow v_{\text{hoop}} = \sqrt{gh}$$

Express the ratio of these speeds to obtain:

$$\frac{v_{\text{coin}}}{v_{\text{hoop}}} = \frac{\sqrt{\tfrac{4}{3} gh}}{\sqrt{gh}} = \sqrt{\tfrac{4}{3}} \Rightarrow v_{\text{coin}} > v_{\text{hoop}}$$

and $\boxed{(b)}$ is correct.

18 •• For a hoop of mass *M* and radius *R* that is rolling without slipping, which is larger, its translational kinetic energy or its rotational kinetic energy? (*a*) Its translational kinetic energy is larger. (*b*) Its rotational kinetic energy is larger. (*c*) Both energies have the same magnitude. (*d*) The answer depends on the radius of the hoop. (*e*) The answer depends on the mass of the hoop.

Picture the Problem We can use the definitions of the translational and rotational kinetic energies of the hoop and the moment of inertia of a hoop (ring) to express and compare the kinetic energies.

Express the ratio of the translational kinetic energy of the hoop to its rotational kinetic energy and simplify to obtain:

$$\frac{K_{\text{trans}}}{K_{\text{rot}}} = \frac{\tfrac{1}{2} mv^2}{\tfrac{1}{2} I_{\text{hoop}} \omega^2} = \frac{mv^2}{\left(mr^2\right)\frac{v^2}{r^2}} = 1$$

Therefore, the translational and rotational kinetic energies are the same and $\boxed{(c)}$ is correct.

19 •• For a disk of mass M and radius R that is rolling without slipping, which is larger, its translational kinetic energy or its rotational kinetic energy? (a) Its translational kinetic energy is larger. (b) Its rotational kinetic energy is larger. (c) Both energies have the same magnitude. (d) The answer depends on the radius of the disk. (e) The answer depends on the mass of the disk.

Picture the Problem We can use the definitions of the translational and rotational kinetic energies of the disk and the moment of inertia of a disk (cylinder) to express and compare the kinetic energies.

Express the ratio of the translational kinetic energy of the disk to its rotational kinetic energy:

$$\frac{K_{\text{trans}}}{K_{\text{rot}}} = \frac{\frac{1}{2}mv^2}{\frac{1}{2}I_{\text{disk}}\omega^2} = \frac{mv^2}{\left(\frac{1}{2}mr^2\right)\frac{v^2}{r^2}} = 2$$

Therefore, the translational kinetic energy is greater by a factor of two and $\boxed{(a)}$ is correct.

20 •• A perfectly rigid ball rolls without slipping along a perfectly rigid horizontal plane. Show that the frictional force acting on the ball must be zero. *Hint: Consider a possible direction for the action of the frictional force and what effects such a force would have on the velocity of the center of mass and on the angular velocity.*

Picture the Problem Let us assume that $f \neq 0$ and acts along the direction of motion. Now consider the acceleration of the center of mass and the angular acceleration about the point of contact with the plane. Because $F_{\text{net}} \neq 0$, $a_{\text{cm}} \neq 0$. However, $\tau = 0$ because $\ell = 0$, and so $\alpha = 0$. But $\alpha = 0$ is not consistent with $a_{\text{cm}} \neq 0$. Consequently, $f = 0$.

21 •• **[SSM]** A spool is free to rotate about a fixed axis, and a string wrapped around the axle of the spool causes the spool to rotate in a counterclockwise direction (see Figure 9-42a). However, if the spool is set on a horizontal tabletop, the spool instead (given sufficient frictional force between the table and the spool) rotates in a clockwise direction, and rolls to the right (Figure 9-42b). By considering torque about the appropriate axes, show that these conclusions are consistent with Newton's second law for rotations.

Determine the Concept First, visualize the situation. The string pulling to the right exerts a torque on the spool with a moment arm equal in length to the radius of the inner portion of the spool. When the spool is freely rotating about that axis, then the torque due to the pulling string causes a counter clockwise rotation. Second, in the situation in which the spool is resting on the horizontal tabletop, one should (for ease of understanding) consider torques not about the central axle of the spool, but about the point of contact with the tabletop. In this situation,

there is only one force that can produce a torque – the applied force. The motion of the spool can then be understood in terms of the force applied by the string and the moment arm equal to the difference between the outer radius and the inner radius. This torque will cause a clockwise rotation about the point of contact between spool and table – and thus the spool rolls to the right (whereas we might have thought the spool would rotate in a counter-clockwise sense, and thus move left).

22 • You want to locate the center of gravity of an arbitrarily shaped flat object. You are told to suspend the object from a point, and to suspend a plumb line from the same point. Then draw a vertical line on the object to represent the plumb line. Next, you repeat the process using a different suspension point. The center of gravity will be at the intersection of the drawn lines. Explain the principle(s) behind this process.

Determine the Concept You are finding positions at which gravity exerts no torque on the object, so the gravitational force (weight) passes through the center of mass. Thus you are triangulating, and in theory, two such lines should intersect at the center of mass. In practice, several lines do a better and more accurate job.

Estimation and Approximation

23 •• A baseball is thrown at 88 mi/h, and with a spin rate of 1500 rev/min. If the distance between the pitcher's point of release and the catcher's glove is about 61 feet, estimate how many revolutions the ball makes between release and catch. Neglect any effects of gravity or air resistance on the ball's flight.

Picture the Problem The number of revolutions made by the ball is the ratio of the angle through which it rotates to 2π rad/rev.

The number of revolutions N the ball makes between release and catch is given by:

$$N = \frac{\Delta\theta}{2\pi\ \text{rad/rev}} \quad (1)$$

where $\Delta\theta$ is the angular displacement of the ball as it travels from the pitcher to the catcher.

Because $\omega = 2\pi f$, $\Delta\theta$ is given by:

$$\Delta\theta = \omega\Delta t = 2\pi f\Delta t$$

Substituting for $\Delta\theta$ in equation (1) yields:

$$N = \frac{2\pi f\Delta t}{2\pi\ \text{rad/rev}} = \frac{f\Delta t}{\text{rad/rev}} \quad (2)$$

Express the time-of-flight of the ball:

$$\Delta t = \frac{d}{v}$$

where d is the distance from the release point to the catcher's glove and v is the speed of the ball.

Substituting for Δt in equation (2) yields:

$$N = \frac{fd}{v \text{ rad/rev}}$$

Substitute numerical values and evaluate N:

$$N = \frac{\left(1500\,\frac{\text{rev}}{\text{min}} \times \frac{1\text{ min}}{60\text{ s}}\right)(61\text{ ft})}{\left(88\,\frac{\text{mi}}{\text{h}} \times \frac{5280\text{ ft}}{\text{mi}} \times \frac{1\text{ h}}{3600\text{ s}}\right)\frac{\text{rad}}{\text{rev}}} \approx \boxed{12\text{ rev}}$$

24 •• Consider the Crab Pulsar, discussed on page 293. Justify the statement that the loss in rotational energy is equivalent to the power output of 100 000 stars. The total power radiated by the Sun is about 4×10^{26} W. Assume that the pulsar has a mass that is 2×10^{30} kg, has a radius that is 20 km, is rotating at about 30 rev/s, and has a rotational period that is increasing at 10^{-5} s/y.

Picture the Problem The power dissipated in the loss of rotational kinetic energy is the rate at which the rotational kinetic energy of the Crab Pulsar is decreasing.

Express the rate at which the rotational kinetic energy of the Crab Pulsar is changing:

$$P_{\text{Crab Pulsar}} = \frac{\Delta K}{\Delta t} = \frac{K_\text{f} - K_\text{i}}{\Delta t}$$

Substitute for K_f and K_i and simplify to obtain:

$$P_{\text{Crab Pulsar}} = \frac{\frac{1}{2}I\omega_\text{f}^2 - \frac{1}{2}I\omega_\text{i}^2}{\Delta t} = \frac{\frac{1}{2}I\left(\omega_\text{f}^2 - \omega_\text{i}^2\right)}{\Delta t}$$

Letting $\omega_\text{f} = \omega_\text{i} - \delta\omega$ yields:

$$P_{\text{Crab Pulsar}} = \frac{\frac{1}{2}I\left[(\omega_\text{i} - \delta\omega)^2 - \omega_\text{i}^2\right]}{\Delta t}$$

Expand the binomial expression and simplify to obtain:

$$P_{\text{Crab Pulsar}} = \frac{\frac{1}{2}I\left[(\delta\omega)^2 - 2\omega_\text{i}\delta\omega\right]}{\Delta t} \quad (1)$$

Express $\delta\omega$ in terms of ω_f and ω_i:

$$\delta\omega = \omega_\text{f} - \omega_\text{i} = \frac{2\pi}{T_\text{f}} - \omega_\text{i}$$

Substituting for T_f and ω_i yields:

$$\delta\omega = \frac{2\pi}{T_i + 10^{-5}\ \text{s}} - 60\pi\ \text{rad/s}$$

Substitute for T_i and simplify to obtain:

$$\delta\omega = \frac{2\pi}{\frac{2\pi}{60\pi}\text{s} + 10^{-5}\ \text{s}} - 60\pi\ \text{rad/s}$$
$$= -0.0565\ \text{s}^{-1}$$

Because $\delta\omega << \omega_i$:

$$(\delta\omega)^2 - 2\omega_i\delta\omega \approx -2\omega_i\delta\omega$$

With this substitution, equation (1) becomes:

$$P_{\text{Crab Pulsar}} = \frac{\frac{1}{2}I[-2\omega_i\delta\omega]}{\Delta t} = \frac{-I\omega_i\delta\omega}{\Delta t} \qquad (2)$$

The moment of inertia of a sphere of mass M and radius R is:

$$I = \tfrac{2}{5}MR^2$$

Substitute for I in equation (2) to obtain:

$$P_{\text{Crab Pulsar}} = \frac{-\frac{2}{5}MR^2\omega_i\delta\omega}{\Delta t} \qquad (3)$$

Dividing both sides of equation (3) by the power radiated by the Sun yields:

$$\frac{P_{\text{Crab Pulsar}}}{P_{\text{Sun}}} = \frac{-\frac{2}{5}MR^2\omega_i\delta\omega}{P_{\text{sun}}}$$

Substitute numerical values and evaluate $P_{\text{Crab Pulsar}}/P_{\text{Sun}}$:

$$\frac{P_{\text{Crab Pulsar}}}{P_{\text{Sun}}} = \frac{-\frac{2}{5}\left(2\times10^{30}\ \text{kg}\right)(20\ \text{km})^2\left(60\pi\ \frac{\text{rad}}{\text{s}}\right)\left(-0.0565\ \text{s}^{-1}\right)}{\left(4\times10^{26}\ \text{W}\right)\left(1\ \text{y}\times\frac{3.156\times10^7\ \text{s}}{\text{y}}\right)} \approx \boxed{10^5}$$

25 •• A 14-kg bicycle has 1.2-m-diameter wheels, each with a mass of 3.0 kg. The mass of the rider is 38 kg. Estimate the fraction of the total kinetic energy of the rider-bicycle system that is associated with rotation of the wheels.

Picture the Problem Assume the wheels are hoops. That is, neglect the mass of the spokes, and express the total kinetic energy of the bicycle and rider. Let M represent the mass of the rider, m the mass of the bicycle, m_w the mass of each bicycle wheel, and r the radius of the wheels.

Express the ratio of the kinetic energy associated with the rotation of the wheels to that associated with the total kinetic energy of the bicycle and rider:

$$\frac{K_{\text{rot}}}{K_{\text{tot}}}=\frac{K_{\text{rot}}}{K_{\text{trans}}+K_{\text{rot}}} \quad (1)$$

Express the translational kinetic energy of the bicycle and rider:

$$K_{\text{trans}}=K_{\text{bicycle}}+K_{\text{rider}}=\tfrac{1}{2}mv^2+\tfrac{1}{2}Mv^2$$

Express the rotational kinetic energy of the bicycle wheels:

$$K_{\text{rot}}=2K_{\text{rot, 1 wheel}}=2\left(\tfrac{1}{2}I_{\text{w}}\omega^2\right)=\left(m_{\text{w}}r^2\right)\frac{v^2}{r^2}=m_{\text{w}}v^2$$

Substitute for K_{rot} and K_{trans} in equation (1) and simplify to obtain:

$$\frac{K_{\text{rot}}}{K_{\text{tot}}}=\frac{m_{\text{w}}v^2}{\frac{1}{2}mv^2+\frac{1}{2}Mv^2+m_{\text{w}}v^2}=\frac{m_{\text{w}}}{\frac{1}{2}m+\frac{1}{2}M+m_{\text{w}}}=\frac{2}{2+\dfrac{m+M}{m_{\text{w}}}}$$

Substitute numerical values and evaluate $K_{\text{rot}}/K_{\text{trans}}$:

$$\frac{K_{\text{rot}}}{K_{\text{tot}}}=\frac{2}{2+\dfrac{14\,\text{kg}+38\,\text{kg}}{3.0\,\text{kg}}}=\boxed{10\%}$$

26 •• Why does toast falling off a table always land jelly-side down? The question may sound silly, but it has been a subject of serious scientific enquiry. The analysis is too complicated to reproduce here, but R. D. Edge and Darryl Steinert showed that a piece of toast, pushed gently over the edge of a table until it tilts off, typically falls off the table when it makes an angle of about 30° with the horizontal (Figure 9-43) and at that instant has an angular speed of $\omega=0.956\sqrt{g/\ell}$, where ℓ is the length of one edge of the piece of toast (assumed to be square). Assuming that a piece of toast is jelly-side up, what side will it land on if it falls from a 0.500-m-high table? If it falls from a 1.00-m-high table? Assume that ℓ = 10.0 cm. Ignore any forces due to air resistance.

Picture the Problem We can apply the definition of angular speed to find the angular orientation of the slice of toast when it has fallen a distance of 0.500 m (or 1.00 m) from the edge of the table. We can then interpret the orientation of the toast to decide whether it lands jelly-side up or down.

Relate the angular orientation θ of the toast to its initial angular orientation, its angular speed ω, and time of fall Δt:

$$\theta=\theta_0+\omega\Delta t$$

Substituting the expression given for ω in the problem statement to obtain:

$$\theta = \theta_0 + 0.956\sqrt{\frac{g}{\ell}}\Delta t \qquad (1)$$

Using a constant-acceleration equation, relate the distance the toast falls Δy to its time of fall Δt:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $a_y = g$,

$$\Delta y = \tfrac{1}{2}g(\Delta t)^2 \Rightarrow \Delta t = \sqrt{\frac{2\Delta y}{g}}$$

Substitute for Δt in equation (1) and simplify to obtain:

$$\theta = \theta_0 + 0.956\sqrt{\frac{g}{\ell}}\sqrt{\frac{2\Delta y}{g}}$$
$$= \theta_0 + 0.956\sqrt{\frac{2\Delta y}{\ell}}$$

Substitute numerical values and evaluate θ for $\Delta y = 0.500$ m:

$$\theta_{0.50\,\text{m}} = \frac{\pi}{6} + 0.956\sqrt{\frac{2(0.500\text{ m})}{0.100\text{ m}}}$$
$$= 3.547\text{ rad} \times \frac{180°}{\pi\text{ rad}}$$
$$= \boxed{203°}$$

Substitute numerical values and evaluate θ for $\Delta y = 1.00$ m:

$$\theta_{1.0\,\text{m}} = \frac{\pi}{6} + 0.956\sqrt{\frac{2(1.00\text{ m})}{0.100\text{ m}}}$$
$$= 4.799\text{ rad} \times \frac{180°}{\pi\text{ rad}}$$
$$= \boxed{275°}$$

The orientation of the slice of toast will therefore be at angles of 203° and 275° with respect to ground; that is, with the jelly-side down.

27 •• Consider your moment of inertia about a vertical axis through the center of your body, both when you are standing straight up with your arms flat against your sides, and when you are standing straight up holding yours arms straight out to the side. Estimate the ratio of the moment of inertia with your arms straight out to the moment of inertia with your arms flat against your sides.

Picture the Problem Assume that the mass of an average adult male is about 80 kg, and that we can model his body when he is standing straight up with his arms at his sides as a cylinder. From experience in men's clothing stores, a man's average waist circumference seems to be about 34 inches, and the average chest circumference about 42 inches. We'll also assume that about 20% of your body's mass is in your two arms, and that each has a length $L = 1$ m, so that each arm has a mass of about $m = 8$ kg.

Letting I_{out} represent his moment of inertia with his arms straight out and I_{in} his moment of inertia with his arms at his side, the ratio of these two moments of inertia is:

$$\frac{I_{out}}{I_{in}} = \frac{I_{body} + I_{arms}}{I_{in}} \qquad (1)$$

Express the moment of inertia of the ″man as a cylinder″:

$$I_{in} = \tfrac{1}{2} MR^2$$

Express the moment of inertia of his arms:

$$I_{arms} = 2\left(\tfrac{1}{3}\right) mL^2$$

Express the moment of inertia of his body-less-arms:

$$I_{body} = \tfrac{1}{2}(M - m)R^2$$

Substitute in equation (1) to obtain:

$$\frac{I_{out}}{I_{in}} = \frac{\tfrac{1}{2}(M - m)R^2 + 2\left(\tfrac{1}{3}\right)mL^2}{\tfrac{1}{2} MR^2}$$

Assume the circumference of the cylinder to be the average of the average waist circumference and the average chest circumference:

$$c_{av} = \frac{34\,\text{in} + 42\,\text{in}}{2} = 38\,\text{in}$$

Find the radius of a circle whose circumference is 38 in:

$$R = \frac{c_{av}}{2\pi} = \frac{38\,\text{in} \times \dfrac{2.54\,\text{cm}}{\text{in}} \times \dfrac{1\,\text{m}}{100\,\text{cm}}}{2\pi} = 0.154\,\text{m}$$

Substitute numerical values and evaluate I_{out}/I_{in}:

$$\frac{I_{out}}{I_{in}} = \frac{\tfrac{1}{2}(80\,\text{kg} - 16\,\text{kg})(0.154\,\text{m})^2 + \tfrac{2}{3}(8\,\text{kg})(1\,\text{m})^2}{\tfrac{1}{2}(80\,\text{kg})(0.154\,\text{m})^2} \approx \boxed{6}$$

Angular Velocity, Angular Speed and Angular Acceleration

28 • A particle moves with a constant speed of 25 m/s in a 90-m-radius circle. (*a*) What is its angular speed, in radians per second, about the center of the circle? (*b*) How many revolutions does it make in 30 s?

Picture the Problem The tangential and angular velocities of a particle moving in a circle are directly proportional. The number of revolutions made by the particle in a given time interval is proportional to both the time interval and its angular speed.

(*a*) Relate the angular speed of the particle to its speed along the circumference of the circle:

$$\omega = \frac{v}{r}$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{25\,\text{m/s}}{90\,\text{m}} = 0.278\,\text{rad/s} = \boxed{0.28\,\text{rad/s}}$$

(*b*) Using a constant-acceleration equation, relate the number of revolutions made by the particle in a given time interval to its angular speed:

$$\Delta\theta = \omega\Delta t = \left(0.278\frac{\text{rad}}{\text{s}}\right)(30\,\text{s})\left(\frac{1\,\text{rev}}{2\pi\,\text{rad}}\right) = \boxed{1.3\,\text{rev}}$$

29 • **[SSM]** A wheel, released from rest, is rotating with constant angular acceleration of 2.6 rad/s^2. At 6.0 s after its release: (*a*) What is its angular speed? (*b*) Through what angle has the wheel turned? (*c*) How many revolutions has it completed? (*d*) What is the linear speed and what is the magnitude of the linear acceleration of a point 0.30 m from the axis of rotation?

Picture the Problem Because the angular acceleration is constant, we can find the various physical quantities called for in this problem by using constant-acceleration equations.

(*a*) Using a constant-acceleration equation, relate the angular speed of the wheel to its angular acceleration:

$$\omega = \omega_0 + \alpha\Delta t$$

or, when $\omega_0 = 0$,

$$\omega = \alpha\Delta t$$

Evaluate ω when Δt = 6.0 s:

$$\omega = (2.6\,\text{rad/s}^2)(6.0\,\text{s}) = 15.6\,\text{rad/s} = \boxed{16\,\text{rad/s}}$$

(*b*) Using another constant-acceleration equation, relate the angular displacement to the wheel's angular acceleration and the time it has been accelerating:

$$\Delta\theta = \omega_0\Delta t + \tfrac{1}{2}\alpha(\Delta t)^2$$

or, when $\omega_0 = 0$,

$$\Delta\theta = \tfrac{1}{2}\alpha(\Delta t)^2$$

Evaluate $\Delta\theta$ when Δt = 6.0 s:

$$\Delta\theta(6.0\,\text{s}) = \tfrac{1}{2}(2.6\,\text{rad/s}^2)(6.0\,\text{s})^2 = 46.8\,\text{rad} = \boxed{47\,\text{rad}}$$

(*c*) Convert $\Delta\theta(6.0\,\text{s})$ from radians to revolutions:

$$\Delta\theta(6.0\,\text{s}) = 46.8\,\text{rad} \times \frac{1\,\text{rev}}{2\pi\,\text{rad}} = \boxed{7.4\,\text{rev}}$$

(*d*) Relate the angular speed of the particle to its tangential speed and evaluate the latter when $\Delta t = 6.0$ s:

$$v = r\omega = (0.30\,\text{m})(15.6\,\text{rad/s})$$
$$= \boxed{4.7\,\text{m/s}}$$

Relate the resultant acceleration of the point to its tangential and centripetal accelerations when $\Delta t = 6.0$ s:

$$a = \sqrt{a_\text{t}^2 + a_\text{c}^2} = \sqrt{(r\alpha)^2 + (r\omega^2)^2}$$
$$= r\sqrt{\alpha^2 + \omega^4}$$

Substitute numerical values and evaluate *a*:

$$a = (0.30\,\text{m})\sqrt{(2.6\,\text{rad/s}^2)^2 + (15.6\,\text{rad/s})^4} = \boxed{73\,\text{m/s}^2}$$

30 • When a turntable rotating at 33 rev/min is shut off, it comes to rest in 26 s. Assuming constant angular acceleration, find (*a*) the angular acceleration. During the 26 s, find (*b*) the average angular speed, and (*c*) the angular displacement, in revolutions.

Picture the Problem Because we're assuming constant angular acceleration; we can find the various physical quantities called for in this problem by using constant-acceleration equations for rotational motion.

(*a*) The angular acceleration of the turntable is given by:

$$\alpha = \frac{\Delta\omega}{\Delta t} = \frac{\omega - \omega_0}{\Delta t}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{0 - 33\dfrac{\text{rev}}{\text{min}} \times \dfrac{2\pi\,\text{rad}}{\text{rev}} \times \dfrac{1\,\text{min}}{60\,\text{s}}}{26\,\text{s}}$$
$$= \boxed{0.13\,\text{rad/s}^2}$$

(*b*) Because the angular acceleration is constant, the average angular speed is given by:

$$\omega_\text{av} = \frac{\omega_0 + \omega}{2}$$

Substitute numerical values and evaluate ω_{av}:

$$\omega_{av} = \frac{33\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}}{2} = 1.73\,\text{rad/s} = \boxed{1.7\,\text{rad/s}}$$

(*c*) Using the definition of ω_{av}, find the angular displacement of the turntable as it slows to a stop:

$$\Delta\theta = \omega_{av}\Delta t = (1.73\,\text{rad/s})(26\,\text{s}) = 44.9\,\text{rad}\times\frac{1\,\text{rev}}{2\pi\,\text{rad}} = \boxed{7.2\,\text{rev}}$$

31 • A 12-cm-radius disk that begins to rotate about its axis at $t = 0$, rotates with a constant angular acceleration of 8.0 rad/s^2. At $t = 5.0$ s, (*a*) what is the angular speed of the disk, and (*b*) what are the tangential and centripetal components of the acceleration of a point on the edge of the disk?

Picture the Problem Because the angular acceleration of the disk is constant, we can use a constant-acceleration equation to relate its angular speed to its acceleration and the time it has been accelerating. We can find the tangential and centripetal accelerations from their relationships to the angular speed and angular acceleration of the disk.

(*a*) Using a constant-acceleration equation, relate the angular speed of the disk to its angular acceleration and time during which it has been accelerating:

$$\omega = \omega_0 + \alpha\,\Delta t$$

or, because $\omega_0 = 0$,

$$\omega = \alpha\,\Delta t$$

Evaluate ω when $t = 5.0$ s:

$$\omega(5.0\,\text{s}) = (8.0\,\text{rad/s}^2)(5.0\,\text{s}) = \boxed{40\,\text{rad/s}}$$

(*b*) Express a_t in terms of α:

$$a_t = r\alpha$$

Evaluate a_t when $t = 5.0$ s:

$$a_t(5.0\,\text{s}) = (0.12\,\text{m})(8.0\,\text{rad/s}^2) = \boxed{0.96\,\text{m/s}^2}$$

Express a_c in terms of ω:

$$a_c = r\omega^2$$

Evaluate a_c when $t = 5.0$ s:

$$a_c(5.0\,\text{s}) = (0.12\,\text{m})(40\,\text{rad/s})^2 = \boxed{0.19\,\text{km/s}^2}$$

32 • A 12-m-radius Ferris wheel rotates once each 27 s. (*a*) What is its angular speed (in radians per second)? (*b*) What is the linear speed of a passenger? (*c*) What is the acceleration of a passenger?

Picture the Problem We can find the angular speed of the Ferris wheel from its definition and the linear speed and centripetal acceleration of the passenger from the relationships between those quantities and the angular speed of the Ferris wheel.

(*a*) Find ω from its definition:

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{2\pi\,\text{rad}}{27\,\text{s}} = 0.233\,\text{rad/s}$$
$$= \boxed{0.23\,\text{rad/s}}$$

(*b*) Find the linear speed of the passenger from his/her angular speed:

$$v = r\omega = (12\,\text{m})(0.233\,\text{rad/s})$$
$$= \boxed{2.8\,\text{m/s}}$$

Find the passenger's centripetal acceleration from his/her angular speed:

$$a_\text{c} = r\omega^2 = (12\,\text{m})(0.233\,\text{rad/s})^2$$
$$= \boxed{0.65\,\text{m/s}^2}$$

33 • A cyclist accelerates uniformly from rest. After 8.0 s, the wheels have rotated 3.0 rev. (*a*) What is the angular acceleration of the wheels? (*b*) What is the angular speed of the wheels at the end of the 8.0 s?

Picture the Problem Because the angular acceleration of the wheels is constant, we can use constant-acceleration equations in rotational form to find their angular acceleration and their angular speed at any given time.

(*a*) Using a constant-acceleration equation, relate the angular displacement of the wheel to its angular acceleration and the time it has been accelerating:

$$\Delta\theta = \omega_0\Delta t + \tfrac{1}{2}\alpha(\Delta t)^2$$

or, because $\omega_0 = 0$,

$$\Delta\theta = \tfrac{1}{2}\alpha(\Delta t)^2 \Rightarrow \alpha = \frac{2\Delta\theta}{(\Delta t)^2}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{2(3.0\,\text{rev})\left(\dfrac{2\pi\,\text{rad}}{\text{rev}}\right)}{(8.0\,\text{s})^2}$$
$$= 0.589\,\text{rad/s}^2 = \boxed{0.59\,\text{rad/s}^2}$$

(*b*) Using a constant-acceleration equation, relate the angular speed of the wheel to its angular acceleration and the time it has been accelerating:

$\omega = \omega_0 + \alpha\Delta t$

or, when $\omega_0 = 0$,

$\omega = \alpha\Delta t$

Evaluate ω when $\Delta t = 8.0$ s:

$$\omega(8.0\,\text{s}) = (0.589\,\text{rad/s}^2)(8.0\,\text{s}) = \boxed{4.7\,\text{rad/s}}$$

34 • What is the angular speed of Earth, in radians per second, as it rotates about its axis?

Picture the Problem Earth rotates through 2π radians every 24 hours.

Apply the definition of angular speed to obtain:

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{2\pi\,\text{rad}}{24\,\text{h}\times\frac{3600\,\text{s}}{\text{h}}} = \boxed{73\,\mu\text{rad/s}}$$

35 • A wheel rotates through 5.0 rad in 2.8 s as it is brought to rest with constant angular acceleration. Determine the wheel's initial angular speed before braking began.

Picture the Problem When the angular acceleration of a wheel is constant, its average angular speed is the average of its initial and final angular velocities. We can combine this relationship with the always applicable definition of angular speed to find the initial angular velocity of the wheel.

Express the average angular speed of the wheel in terms of its initial and final angular speeds:

$$\omega_{av} = \frac{\omega_0 + \omega}{2}$$

or, because $\omega = 0$,

$$\omega_{av} = \tfrac{1}{2}\omega_0$$

The average angular speed of the wheel is also given by:

$$\omega_{av} = \frac{\Delta\theta}{\Delta t}$$

Equate these two expressions for ω_{av} and solve for ω_0 to obtain:

$$\omega_0 = \frac{2\Delta\theta}{\Delta t}$$

Substitute numerical values and evaluate ω_0:

$$\omega_0 = \frac{2(5.0\,\text{rad})}{2.8\,\text{s}} = \boxed{3.6\,\text{rad/s}}$$

36 • A bicycle has 0.750-m-diameter wheels. The bicyclist accelerates from rest with constant acceleration to 24.0 km/h in 14.0 s. What is the angular acceleration of the wheels?

Picture the Problem The tangential and angular accelerations of the wheel are directly proportional to each other with the radius of the wheel as the proportionality constant. Provided there is no slippage, the acceleration of a point on the rim of the wheel is the same as the acceleration of the bicycle. We can use its defining equation to determine the acceleration of the bicycle.

Relate the tangential acceleration of a point on the wheel (equal to the acceleration of the bicycle) to the wheel's angular acceleration and solve for its angular acceleration:

$$a = a_{\mathrm{t}} = r\alpha \Rightarrow \alpha = \frac{a}{r}$$

Use its definition to express the acceleration of the wheel:

$$a = \frac{\Delta v}{\Delta t} = \frac{v - v_0}{\Delta t}$$

or, because $v_0 = 0$,

$$a = \frac{v}{\Delta t}$$

Substitute in the expression for α to obtain:

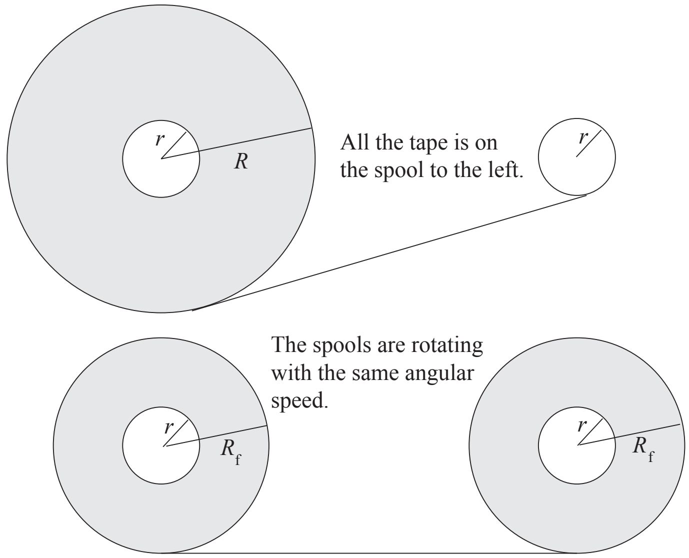
$$\alpha = \frac{v}{r\Delta t} = \frac{v}{\frac{1}{2}d\Delta t} = \frac{2v}{d\Delta t}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{2\left(24.0\,\frac{\text{km}}{\text{h}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)\left(\frac{1000\,\text{m}}{\text{km}}\right)}{(0.750\,\text{m})(14.0\,\text{s})} = \boxed{1.3\,\text{rad/s}^2}$$

37 •• **[SSM]** The tape in a standard VHS videotape cassette has a total length of 246 m, which is enough for the tape to play for 2.0 h (Figure 9-44). As the tape starts, the full reel has a 45-mm outer radius and a 12-mm inner radius. At some point during the play, both reels have the same angular speed. Calculate this angular speed in radians per second and in revolutions per minute. (*Hint: Between the two reels the tape moves at constant speed.*)

Picture the Problem The two tapes will have the same tangential and angular velocities when the two reels are the same size, i.e., have the same area. We can calculate the tangential speed of the tape from its length and running time and relate the angular speed to the constant tangential speed and the radii of the reels when they are turning with the same angular speed.



Relate the angular speed of a tape to its tangential speed when the tapes have the same angular speed:

$$\omega_f = \frac{v}{R_f} \qquad (1)$$

At the instant both reels have the same area:

$$\pi R_f^2 - \pi r^2 = \tfrac{1}{2}\left(\pi R^2 - \pi r^2\right)$$

Solving for R_f yields:

$$R_f = \sqrt{\frac{R^2 + r^2}{2}}$$

Express the tangential speed of the tape in terms of its length L and running time T:

$$v = \frac{L}{T}$$

Substituting or R_f and v in equation (1) gives:

$$\omega_f = \frac{\frac{L}{T}}{\sqrt{\frac{R^2 + r^2}{2}}} = \frac{L}{T}\sqrt{\frac{2}{R^2 + r^2}}$$

Substitute numerical values and evaluate R_f:

$$\omega_f = \frac{246\ \text{m}}{2.0\ \text{h} \times \frac{3600\ \text{s}}{\text{h}}}\sqrt{\frac{2}{(45\ \text{mm})^2 + (12\ \text{mm})^2}} = 1.04\ \text{rad/s} = \boxed{1.0\ \text{rad/s}}$$

$$= 1.04\ \frac{\text{rad}}{\text{s}} \times \frac{1\ \text{rev}}{2\pi\ \text{rad}} \times \frac{60\ \text{s}}{\text{min}} = \boxed{9.9\ \text{rev/min}}$$

38 •• To start a lawn mower, you must pull on a rope wound around the perimeter of a flywheel. After you pull the rope for 0.95 s, the flywheel is rotating at 4.5 revolutions per second, at which point the rope disengages. This attempt at starting the mower does not work, however, and the flywheel slows, coming to rest 0.24 s after the disengagement. Assume constant acceleration during both spin up and spin down. (*a*) Determine the average angular acceleration during the 4.5-s spin-up and again during the 0.24-s spin-down. (*b*) What is the maximum angular speed reached by the flywheel? (*c*) Determine the ratio of the number of revolutions made during spin-up to the number made during spin-down.

Picture the Problem The average angular acceleration of the starter is the ratio of the change in angular speed to the time during which the starter either speeds up slows down. The number of revolutions through which the starter turns is the product of its average angular speed and the elapsed time.

(*a*) The average angular acceleration of the starter is given by:

$$\alpha_{av} = \frac{\Delta\omega}{\Delta t} = \frac{\omega_f - \omega_i}{\Delta t}$$

Evaluate α_{av} for $\omega_i = 0$ and $\omega_f = 4.5$ rev/s:

$$\alpha_{av} = \frac{4.5\,\frac{\text{rev}}{\text{s}}\times\frac{2\pi\ \text{rad}}{\text{rev}} - 0}{0.95\ \text{s}} = 29.8\ \text{rad/s}^2$$

$$= \boxed{30\ \text{rad/s}^2}$$

Evaluate α_{av} for $\omega_i = 4.5$ rev/s and $\omega_f = 0$:

$$\alpha_{av} = \frac{0 - 4.5\,\frac{\text{rev}}{\text{s}}\times\frac{2\pi\ \text{rad}}{\text{rev}}}{0.24\ \text{s}}$$

$$= -118\ \text{rad/s}^2 = \boxed{-1.2\times10^2\ \text{rad/s}^2}$$

(*b*) The maximum angular speed reached by the starter is the angular speed it had when the rope comes off:

$$\omega_{max} = 4.5\,\frac{\text{rev}}{\text{s}}\times\frac{2\pi\ \text{rad}}{\text{rev}} = \boxed{28\ \text{rad/s}}$$

(*c*) Use a constant-acceleration equation to express the ratio of the number of revolutions during startup to the number of revolutions during slowdown:

$$\frac{\Delta\theta_{\text{spin up}}}{\Delta\theta_{\text{spin down}}} = \frac{\omega_{\text{av,spin up}}(\Delta t)_{\text{spin up}}}{\omega_{\text{av,spin down}}(\Delta t)_{\text{spin down}}}$$

or, because $\omega_{\text{av, spin up}} = \omega_{\text{av, spin down}}$,

$$\frac{\Delta\theta_{\text{spin up}}}{\Delta\theta_{\text{spin down}}} = \frac{(\Delta t)_{\text{spin up}}}{(\Delta t)_{\text{spin down}}}$$

Substitute numerical values and evaluate $\Delta\theta_{\text{spin up}}/\Delta\theta_{\text{spin down}}$:

$$\frac{\Delta\theta_{\text{spin up}}}{\Delta\theta_{\text{spin down}}}=\frac{0.95\text{ s}}{0.24\text{ s}}=\boxed{4.0}$$

39 ••• Mars orbits the Sun at a mean orbital radius of 228 Gm (1 Gm = 10^9 m) and has an orbital period of 687 d. Earth orbits the Sun at a mean orbital radius of 149.6 Gm. (*a*) The Earth-Sun line sweeps out an angle of 360° during one Earth year. Approximately what angle is swept out by the Mars-Sun line during one Earth-year? (*b*) How frequently are Mars and the Sun in opposition (on diametrically opposite sides of Earth)?

Picture the Problem Two solutions for Part (*a*), both based on the definition of average angular speed ($\omega=\Delta\theta/\Delta t$) are given below.

(*a*) **First solution** The angle between the Earth-Sun line and the Mars-Sun line is given by:

$$\theta=\left(\frac{\Delta\theta}{\Delta t}\right)_{\text{Mars}}\Delta t$$

where $\left(\frac{\Delta\theta}{\Delta t}\right)_{\text{Mars}}=\frac{2\pi\text{ rad}}{687\text{ d}}$ is the rate at which the angle between the Earth-Sun line and the Mars-Sun line is swept out.

For Δt = 365.24 d (one Earth year):

$$\theta=\left(\frac{2\pi\text{ rad}}{687\text{ d}}\right)(365.24\text{ d})=\boxed{3.34\text{ rad}}$$

A second solution This solution assumes that the question is "If Earth and Mars have the same angular coordinate at t = 0, what will be the angle between the Earth-Sun and Mars-Sun lines when t = 1.0 y (Earth year)?" Let θ_E = 0 and θ_M = 0 at t = 0 and let T_E = orbital period of Earth = 365.24 d.

The angles through which the Mars-Sun and Earth-Sun lines rotate in time Δt are given by:

$$\theta_M=\left(\frac{\Delta\theta}{\Delta t}\right)_M\Delta t$$

and

$$\theta_E=\left(\frac{\Delta\theta}{\Delta t}\right)_E\Delta t$$

Subtracting the first equation from the second equation gives:

$$\theta_E-\theta_M=\left(\frac{\Delta\theta}{\Delta t}\right)_E\Delta t-\left(\frac{\Delta\theta}{\Delta t}\right)_M\Delta t$$

At the end of one Earth year $\left(\frac{\Delta\theta}{\Delta t}\right)_E\Delta t=2\pi$ and $\theta_M=\left(\frac{\Delta\theta}{\Delta t}\right)_M T_E$:

$$\theta_E-\theta_M=2\pi-\left(\frac{\Delta\theta}{\Delta t}\right)_M T_E$$

Substitute numerical values for $\Delta\theta$, Δt and T_E and evaluate $\theta_E - \theta_M$:

$$\theta_E - \theta_M = 2\pi - \left(\frac{2\pi}{687\text{ d}}\right)(365.24\text{ d})$$
$$= 2\pi\left(1 - \frac{365.24}{687}\right)$$
$$= \boxed{2.94\text{ rad}}$$

(*b*) The second alignment of Earth and Mars will occur when both planets have the same angular displacement from their initial alignment-with Earth having made one full revolution more than Mars:

$$\theta_{\text{Earth}} = \omega_{\text{Earth}}\Delta t = 2\pi + \theta_{\text{Mars}} \quad (1)$$

The angular position of Mars at this time is:

$$\theta_{\text{Mars}} = \omega_{\text{Mars}}\Delta t \quad (2)$$

Substituting for θ_{Mars} in equation (1) yields:

$$\omega_{\text{Earth}}\Delta t = 2\pi + \omega_{\text{Mars}}\Delta t$$

Solve for Δt to obtain:

$$\Delta t = \frac{2\pi}{\omega_{\text{Earth}} - \omega_{\text{Mars}}} \quad (3)$$

The angular speeds of Earth and Mars are related to their periods:

$$\omega_{\text{Earth}} = \frac{2\pi}{T_{\text{Earth}}} \text{ and } \omega_{\text{Mars}} = \frac{2\pi}{T_{\text{Mars}}}$$

Substituting for ω_{Earth} and ω_{Mars} in equation (3) and simplifying yields:

$$\Delta t = \frac{2\pi}{\frac{2\pi}{T_{\text{Earth}}} - \frac{2\pi}{T_{\text{Mars}}}} = \frac{T_{\text{Earth}}T_{\text{Mars}}}{T_{\text{Mars}} - T_{\text{Earth}}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{(365.24\text{ d})(687\text{ d})}{687\text{ d} - 365.24\text{ d}} = \boxed{780\text{ d}}$$

Calculating the Moment of Inertia

40 • A tennis ball has a mass of 57 g and a diameter of 7.0 cm. Find the moment of inertia about its diameter. Model the ball as a thin spherical shell.

Picture the Problem One can find the formula for the moment of inertia of a thin spherical shell in Table 9-1.

The moment of inertia of a thin spherical shell about its diameter is:

$$I = \tfrac{2}{3}MR^2$$

Substitute numerical values and evaluate I:

$$I = \tfrac{2}{3}(0.057\,\text{kg})(0.035\,\text{m})^2$$
$$= \boxed{4.7\times10^{-5}\,\text{kg}\cdot\text{m}^2}$$

41 • **[SSM]** Four particles, one at each of the four corners of a square with 2.0-m long edges, are connected by massless rods (Figure 9-45). The masses of the particles are $m_1 = m_3 = 3.0$ kg and $m_2 = m_4 = 4.0$ kg. Find the moment of inertia of the system about the z axis.

Picture the Problem The moment of inertia of a system of particles with respect to a given axis is the sum of the products of the mass of each particle and the square of its distance from the given axis.

Use the definition of the moment of inertia of a system of four particles to obtain:

$$I = \sum_{\text{i}} m_{\text{i}} r_{\text{i}}^2$$
$$= m_1r_1^2 + m_2r_2^2 + m_3r_3^2 + m_4r_4^2$$

Substitute numerical values and evaluate I_z:

$$I_z = (3.0\,\text{kg})(2.0\,\text{m})^2 + (4.0\,\text{kg})(0)^2 + (3.0\,\text{kg})(2.0\,\text{m})^2 + (4.0\,\text{kg})\left(2\sqrt{2}\,\text{m}\right)^2$$
$$= \boxed{56\,\text{kg}\cdot\text{m}^2}$$

42 •• Use the parallel-axis theorem and the result for Problem 41 to find the moment of inertia of the four-particle system in Figure 9-45 about an axis that passes through the center of mass and is parallel with the z axis. Check your result by direct computation.

Picture the Problem According to the parallel-axis theorem, $I = I_{\text{cm}} + Mh^2$, where I_{cm} is the moment of inertia of the object with respect to an axis through its center of mass, M is the mass of the object, and h is the distance between the parallel axes. Note that the center of mass of the system is at the intersection of the diagonals connecting the four masses.

Use the parallel-axis theorem to obtain an expression for I_{cm}:

$$I_z = I_{\text{cm}} + Mh^2 \Rightarrow I_{\text{cm}} = I_z - Mh^2$$

By symmetry:

$$x_{\text{cm}} = 1.0\,\text{m and } y_{\text{cm}} = 1.0\,\text{m}$$

Find the square of the distance from the center of mass to the z axis (note that this distance is also the distance from the center of mass to the center of the object whose mass is m_2):

$$h^2 = r_2^2 = (1.0\,\text{m} - 0)^2 + (1.0\,\text{m} - 0)^2 = 2.0\,\text{m}^2$$

Substitute numerical values in equation (1) and evaluate I_{cm}:

$$I_{\text{cm}} = 56\,\text{kg}\cdot\text{m}^2 - (14\,\text{kg})(2.0\,\text{m}^2) = \boxed{28\,\text{kg}\cdot\text{m}^2}$$

I_{cm} is also given by:

$$I_{\text{cm}} = m_1r_1^2 + m_2r_2^2 + m_3r_3^2 + m_4r_4^2$$

Because $m_1 = m_3$, $m_2 = m_4$, $r_1^2 = r_3^2$ and $r_2^2 = r_4^2$, the expression for I_{cm} becomes:

$$I_{\text{cm}} = 2\left(m_1r_1^2 + m_2r_2^2\right)$$

Substitute numerical values and evaluate I_{cm}:

$$I_{\text{cm}} = 2\left[(3.0\,\text{kg})\left(\sqrt{2.0\,\text{m}}\right)^2 + (4.0\,\text{kg})\left(\sqrt{2.0\,\text{m}}\right)^2\right] = \boxed{28\,\text{kg}\cdot\text{m}^2}$$

43 • For the four-particle system of Figure 9-45, (*a*) find the moment of inertia I_x about the x axis, which passes through m_2 and m_3, and (*b*) find the moment of inertia I_y about the y axis, which passes through m_1 and m_2.

Picture the Problem The moment of inertia of a system of particles with respect to a given axis is the sum of the products of the mass of each particle and the square of its distance from the given axis.

(*a*) Apply the definition of the moment of inertia of a system of particles to express I_x:

$$I_x = \sum_i m_i r_i^2 = m_1r_1^2 + m_2r_2^2 + m_3r_3^2 + m_4r_4^2$$

Substitute numerical values and evaluate I_x:

$$I_x = (3.0\,\text{kg})(2.0\,\text{m})^2 + (4.0\,\text{kg})(0)^2 + (3.0\,\text{kg})(0)^2 + (4.0\,\text{kg})(2.0\,\text{m})^2 = \boxed{28\,\text{kg}\cdot\text{m}^2}$$

(*b*) Apply the definition of the moment of inertia of a system of particles to express I_y:

$$I_y = \sum_i m_i r_i^2 = m_1r_1^2 + m_2r_2^2 + m_3r_3^2 + m_4r_4^2$$

Substitute numerical values and evaluate I_y:

$$I_y = (3.0\,\text{kg})(0)^2 + (4.0\,\text{kg})(0)^2 + (3.0\,\text{kg})(2.0\,\text{m})^2 + (4.0\,\text{kg})(2.0\,\text{m})^2 = \boxed{28\,\text{kg}\cdot\text{m}^2}$$

44 • Determine the moment of inertia of a uniform solid sphere of mass M and radius R about an axis that is tangent to the surface of the sphere (Figure 9-46).

Picture the Problem According to the parallel-axis theorem, $I = I_{\text{cm}} + Mh^2$, where I_{cm} is the moment of inertia of the object with respect to an axis through its center of mass, M is the mass of the object, and h is the distance between the parallel axes.

The moment of inertia of a solid sphere of mass M and radius R about an axis that is tangent to the sphere is given by:

$$I = I_{\text{cm}} + Mh^2 \quad (1)$$

Use Table 9-1 to find the moment of inertia of a sphere with respect to an axis through its center of mass:

$$I_{\text{cm}} = \tfrac{2}{5}MR^2$$

Substitute for I_{cm} and h in equation (1) and simplify to obtain:

$$I = \tfrac{2}{5}MR^2 + MR^2 = \boxed{\tfrac{7}{5}MR^2}$$

45 •• A 1.00-m-diameter wagon wheel consists of a thin rim having a mass of 8.00 kg and 6 spokes, each with a mass of 1.20 kg. Determine the moment of inertia of the wagon wheel about its axis.

Picture the Problem The moment of inertia of the wagon wheel is the sum of the moments of inertia of the rim and the six spokes.

Express the moment of inertia of the wagon wheel as the sum of the moments of inertia of the rim and the spokes:

$$I_{\text{wheel}} = I_{\text{rim}} + I_{\text{spokes}} \quad (1)$$

Using Table 9-1, find formulas for the moments of inertia of the rim and spokes:

$$I_{\text{rim}} = M_{\text{rim}}R^2$$

and

$$I_{\text{spoke}} = \tfrac{1}{3}M_{\text{spoke}}L^2$$

Substitute for I_{rim} and I_{spoke} in equation (1) to obtain:

$$I_{\text{wheel}} = M_{\text{rim}}R^2 + 6\left(\tfrac{1}{3}M_{\text{spoke}}L^2\right) = M_{\text{rim}}R^2 + 2M_{\text{spoke}}L^2$$

Substitute numerical values and evaluate I_{wheel}:

$$I_{\text{wheel}} = (8.00\,\text{kg})(0.50\,\text{m})^2 + 2(1.20\,\text{kg})(0.50\,\text{m})^2 = \boxed{2.6\,\text{kg}\cdot\text{m}^2}$$

46 •• Two point masses m_1 and m_2 are separated by a massless rod of length L. (*a*) Write an expression for the moment of inertia I about an axis perpendicular to the rod and passing through it a distance x from mass m_1. (*b*) Calculate dI/dx and show that I is at a minimum when the axis passes through the center of mass of the system.

Picture the Problem The moment of inertia of a system of particles depends on the axis with respect to which it is calculated. Once this choice is made, the moment of inertia is the sum of the products of the mass of each particle and the square of its distance from the chosen axis.

(*a*) Apply the definition of the moment of inertia of a system of particles:

$$I = \sum_i m_i r_i^2 = \boxed{m_1x^2 + m_2(L-x)^2}$$

(*b*) Set the derivative of I with respect to x equal to zero in order to identify values for x that correspond to either maxima or minima:

$$\frac{dI}{dx} = 2m_1x + 2m_2(L-x)(-1) = 2(m_1x + m_2x - m_2L) = 0 \text{ for extrema}$$

If $\frac{dI}{dx} = 0$, then:

$$m_1x + m_2x - m_2L = 0$$

Solving for x yields:

$$x = \frac{m_2L}{m_1 + m_2}$$

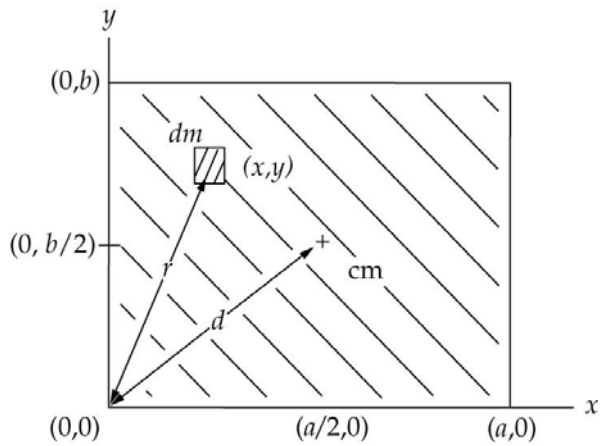
Convince yourself that you've found a minimum by showing that d^2I/dx^2 is positive at this point.

$\boxed{x = \frac{m_2L}{m_1+m_2} \text{ is, by definition, the distance of the center of mass from } m_1.}$

47 •• A uniform rectangular plate has mass m and edges of lengths a and b. (*a*) Show by integration that the moment of inertia of the plate about an axis that is perpendicular to the plate and passes through one corner is $m(a^2 + b^2)/3$.

(*b*) What is the moment of inertia about an axis that is perpendicular to the plate and passes through its center of mass?

Picture the Problem Let σ be the mass per unit area of the uniform rectangular plate. Then the elemental unit has mass $dm = \sigma\, dxdy$. Let the corner of the plate through which the axis runs be the origin. The distance of the element whose mass is dm from the corner r is related to the coordinates of dm through the Pythagorean relationship $r^2 = x^2 + y^2$.



(*a*) Express the moment of inertia of the element whose mass is dm with respect to an axis perpendicular to it and passing through one of the corners of the uniform rectangular plate:

$$dI = \sigma\left(x^2 + y^2\right)dxdy$$

Integrate this expression to find I:

$$I = \sigma\int_0^a\int_0^b\left(x^2 + y^2\right)dxdy = \tfrac{1}{3}\sigma\left(a^3b + ab^3\right)$$

$$= \boxed{\tfrac{1}{3}m\left(a^2 + b^2\right)}$$

(*b*) Letting d represent the distance from the origin to the center of mass of the plate, use the parallel axis theorem to relate the moment of inertia found in (*a*) to the moment of inertia with respect to an axis through the center of mass:

$$I = I_{\text{cm}} + md^2$$

or

$$I_{\text{cm}} = I - md^2 = \tfrac{1}{3}m\left(a^2 + b^2\right) - md^2$$

Using the Pythagorean theorem, relate the distance d to the center of mass to the lengths of the sides of the plate:

$$d^2 = \left(\tfrac{1}{2}a\right)^2 + \left(\tfrac{1}{2}b\right)^2 = \tfrac{1}{4}\left(a^2 + b^2\right)$$

Substitute for d^2 in the expression for I_{cm} and simplify to obtain:

$$I_{\text{cm}} = \tfrac{1}{3}m\left(a^2 + b^2\right) - \tfrac{1}{4}m\left(a^2 + b^2\right)^2$$
$$= \boxed{\tfrac{1}{12}m\left(a^2 + b^2\right)}$$

48 •• In attempting to ensure a spot on the pep squad, you and your friend Corey research baton-twirling. Each of you is using "The Beast" as a model baton: two uniform spheres, each of mass 500 g and radius 5.00 cm, mounted at the ends of a 30.0-cm uniform rod of mass 60.0 g (Figure 9-47). You want to determine the moment of inertia I of "The Beast" about an axis perpendicular to the rod and passing through its center. Corey uses the approximation that the two spheres can be treated as point particles that are 20.0 cm from the axis of rotation, and that the mass of the rod is negligible. You, however, decide to do an exact calculation. (*a*) Compare the two results. (Give the percentage difference between them). (*b*) Suppose the spheres were replaced by two thin spherical shells, each of the same mass as the original solid spheres. Give a conceptual argument explaining how this replacement would, or would not, change the value of I.

Picture the Problem Corey will use the point-particle relationship $I_{\text{app}} = \sum_{\text{i}} m_{\text{i}} r_{\text{i}}^2 = m_1 r_1^2 + m_2 r_2^2$ for his calculation whereas your calculation will take into account not only the rod but also the fact that the spheres are not point particles.

(*a*) Using the point-mass approximation and the definition of the moment of inertia of a system of particles, express I_{app}:

$$I_{\text{app}} = \sum_{\text{i}} m_{\text{i}} r_{\text{i}}^2 = m_1 r_1^2 + m_2 r_2^2$$

Substitute numerical values and evaluate I_{app}:

$$I_{\text{app}} = (0.500\,\text{kg})(0.200\,\text{m})^2 + (0.500\,\text{kg})(0.200\,\text{m})^2 = 0.0400\,\text{kg}\cdot\text{m}^2$$

Express the moment of inertia of the two spheres and connecting rod system:

$$I = I_{\text{spheres}} + I_{\text{rod}}$$

Use Table 9-1 to find the moments of inertia of a sphere (with respect to its center of mass) and a rod (with respect to an axis through its center of mass):

$I_{\text{sphere}} = \frac{2}{5} M_{\text{sphere}} R^2$

and

$I_{\text{rod}} = \frac{1}{12} M_{\text{rod}} L^2$

Because the spheres are not on the axis of rotation, use the parallel axis theorem to express their moment of inertia with respect to the axis of rotation:

$I_{\text{sphere}} = \frac{2}{5} M_{\text{sphere}} R^2 + M_{\text{sphere}} h^2$

where h is the distance from the center of mass of a sphere to the axis of rotation.

Substitute to obtain:

$I = 2\left[\frac{2}{5} M_{\text{sphere}} R^2 + M_{\text{sphere}} h^2\right] + \frac{1}{12} M_{\text{rod}} L^2$

Substitute numerical values and evaluate I:

$$I = 2\left[\tfrac{2}{5}(0.500\,\text{kg})(0.0500\,\text{m})^2 + (0.500\,\text{kg})(0.200\,\text{m})^2\right] + \tfrac{1}{12}(0.0600\,\text{kg})(0.300\,\text{m})^2$$
$$= 0.0415\,\text{kg}\cdot\text{m}^2$$

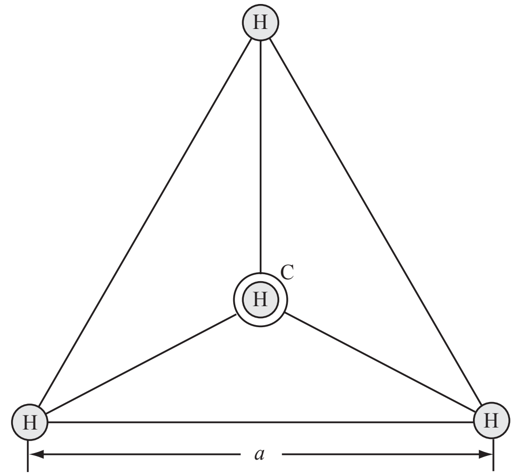
The percent difference between I and I_{app} is:

$$\frac{I - I_{\text{app}}}{I} = \frac{0.0415\,\text{kg}\cdot\text{m}^2 - 0.0400\,\text{kg}\cdot\text{m}^2}{0.0415\,\text{kg}\cdot\text{m}^2} = \boxed{3.6\ \%}$$

(*b*) The rotational inertia would increase because I_{cm} of a hollow sphere is greater than I_{cm} of a solid sphere.

49 •• The methane molecule (CH_4) has four hydrogen atoms located at the vertices of a regular tetrahedron of edge length 0.18 nm, with the carbon atom at the center of the tetrahedron (Figure 9-48). Find the moment of inertia of this molecule for rotation about an axis that passes through the centers of the carbon atom and one of the hydrogen atoms.

Picture the Problem The axis of rotation passes through the center of the base of the tetrahedron. The carbon atom and the hydrogen atom at the apex of the tetrahedron do not contribute to I because the distance of their nuclei from the axis of rotation is zero. From the geometry, the distance of the three H nuclei from the rotation axis is $a/\sqrt{3}$, where a is the length of a side of the tetrahedron.



Apply the definition of the moment of inertia for a system of particles to obtain:

$$I = \sum_i m_i r_i^2 = m_H r_1^2 + m_H r_2^2 + m_H r_3^2$$

$$= 3m_H\left(\frac{a}{\sqrt{3}}\right)^2 = m_H a^2$$

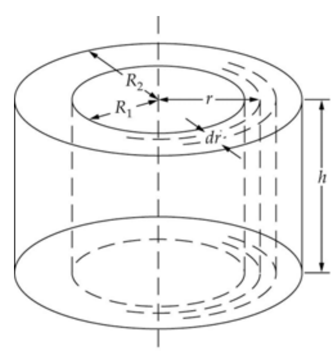
Substitute numerical values and evaluate I:

$$I = \left(1.67\times10^{-27}\ \text{kg}\right)\left(0.18\times10^{-9}\ \text{m}\right)^2$$

$$= \boxed{5.4\times10^{-47}\ \text{kg}\cdot\text{m}^2}$$

50 •• A hollow cylinder has mass m, an outside radius R_2, and an inside radius R_1. Use integration to show that the moment of inertia about its axis is given by $I = \frac{1}{2}m\left(R_2^2 + R_1^2\right)$. *Hint: Review Section 9-3, where the moment of inertia is calculated for a solid cylinder by direct integration.*

Picture the Problem Let the mass of the element of volume dV be $dm = \rho dV = 2\pi\rho hrdr$ where h is the height of the cylinder. We'll begin by expressing the moment of inertia dI for the element of volume and then integrating it between R_1 and R_2.



Express the moment of inertia of an element of mass dm:

$$dI = r^2 dm = 2\pi\rho\, hr^3 dr$$

Integrate dI from R_1 to R_2 to obtain:

$$I = 2\pi\rho h\int_{R_1}^{R_2} r^3 dr = \tfrac{1}{2}\pi\rho h\left(R_2^4 - R_1^4\right)$$
$$= \tfrac{1}{2}\pi\rho h\left(R_2^2 - R_1^2\right)\left(R_2^2 + R_1^2\right)$$

The mass of the hollow cylinder is $m = \pi\rho h\left(R_2^2 - R_1^2\right)$, so:

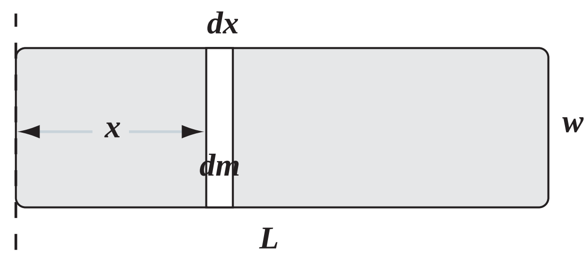
$$\rho = \frac{m}{\pi h\left(R_2^2 - R_1^2\right)}$$

Substitute for ρ and simplify to obtain:

$$I = \tfrac{1}{2}\pi\left(\frac{m}{\pi h\left(R_2^2 - R_1^2\right)}\right)h\left(R_2^2 - R_1^2\right)\left(R_2^2 + R_1^2\right) = \boxed{\tfrac{1}{2}m\left(R_2^2 + R_1^2\right)}$$

51 •• While slapping the water's surface with his tail to communicate danger, a beaver must rotate it about one of its narrow ends. Let us model the tail as a rectangle of uniform thickness and density (Figure 9-49). Estimate its moment of inertia about the line passing through its narrow end (dashed line). Assume the tail measures 15 by 30 cm with a thickness of 1.0 cm and that the flesh has the density of water.

Picture the Problem The pictorial representation shows our model of the beaver tail pivoted about the dashed line shown to the left. We can apply $I = \int x^2 dm$ to this configuration to derive an expression for the moment of inertia of the beaver tail.



The moment of inertia, about an axis through the short side of the rectangular object, is:

$$I = \int x^2 dm$$

Letting the density of the beaver's tail be represented by ρ:

$$dm = \rho dV = \rho wtdx$$

Substituting for dm yields:

$$I = \int \rho wtx^2 dx = \rho wt\int x^2 dx$$

Integrating over the length L of the beaver's tail yields:

$$I = \rho wt\int_0^L x^2 dx = \tfrac{1}{3}\rho wtL^3$$

Substitute numerical values and evaluate I:

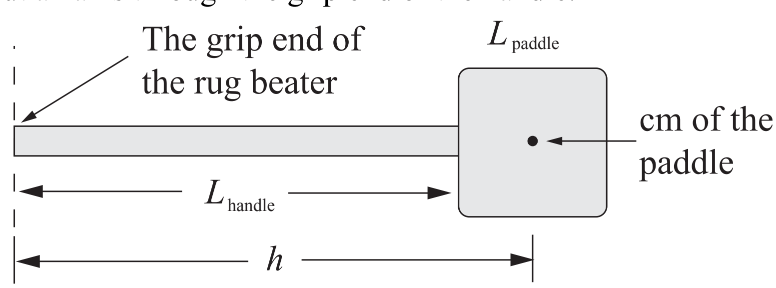
$$I = \tfrac{1}{3}\left(1.0\,\frac{\text{g}}{\text{cm}^3}\right)(15\text{ cm})(1.0\text{ cm})(30\text{ cm})^3$$

$$= \boxed{0.045\text{ kg}\cdot\text{m}^2}$$

Remarks: Had we substituted $m = \rho wtL$ in the expression for I, we would have obtained $I = \frac{1}{3}mL^2$ as the expression for the moment of inertia, about an axis through its short side, of a rectangular plate of uniform thickness.

52 •• To prevent damage to her shoulders, your elderly grandmother wants to purchase the rug beater (Figure 9-50) with the lowest moment of inertia about its grip end. Knowing you are taking physics, she asks your advice. There are two models to choose from. Model A has a 1.0-m-long handle on a 40-cm-edge-length square, where the masses of the handle and square are 1.0 kg and 0.50 kg, respectively. Model B has a 0.75-m-long handle and a 30-cm-edge-length square, where the masses of the handle and square are 1.5 kg and 0.60 kg, respectively. Which model should you recommend? Determine which beater is easiest to swing from the very end by computing the moment of inertia for both beaters.

Picture the Problem We can model the paddles attached to the handles of the rug beaters as point masses. The moment of inertia of the rug beaters can then be expressed as the sum of the moment of inertia of their handles and the moment of inertia of the point masses. Let the subscript A refer to Model A and the subscript B to Model B and find the moments of inertia of the two models. The rug beater that is easiest for your grandmother to use is the one with the smaller moment of inertia about an axis through the grip end of the handle.



The moment of inertia of Model A is:

$$I_{\text{A}} = I_{\text{handle, A}} + I_{\text{paddle, A}}$$

From Table 9-1:

$$I_{\text{handle, A}} = \tfrac{1}{3}m_{\text{handle, A}}L_{\text{handle, A}}^2$$

The moment of inertia of the point-mass paddle is given by:

$$I_{\text{paddle, A}} = m_{\text{paddle, A}} h_{\text{A}}^2$$

where h_A is the sum of L_A and half the width of the paddle.

Substituting for $I_{\text{handle, A}}$ and $I_{\text{paddle, A}}$ gives:

$$I_{\text{A}} = \tfrac{1}{3} m_{\text{handle, A}} L_{\text{handle, A}}^2 + m_{\text{paddle, A}} h_{\text{A}}^2$$

Substitute numerical values and evaluate I_A:

$$I_{\text{A}} = \tfrac{1}{3}(1.0\ \text{kg})(1.0\ \text{m})^2 + (0.50\ \text{kg})(1.2\ \text{m})^2 = 1.05\ \text{kg}\cdot\text{m}^2$$

Similarly, for Model B:

$$I_{\text{B}} = \tfrac{1}{3} m_{\text{handle, B}} L_{\text{handle, B}}^2 + m_{\text{paddle, B}} h_{\text{B}}^2$$

Substitute numerical values and evaluate I_B:

$$I_{\text{B}} = \tfrac{1}{3}(1.5\ \text{kg})(0.75\ \text{m})^2 + (0.60\ \text{kg})(0.81\ \text{m})^2 = 0.77\ \text{kg}\cdot\text{m}^2$$

Because its moment of inertia is smaller that that of the less massive rug beater, the more massive rug beater (Model B) will be easier to use.

Remarks: These point-mass approximation results agree to within 0.7% with those obtained modeling the paddles as rectangles.

53 ••• [SSM] Use integration to show that the moment of inertia of a thin spherical shell of radius R and mass m about an axis through its center is $2mR^2/3$.

Picture the Problem We can derive the given expression for the moment of inertia of a spherical shell by following the procedure outlined in the problem statement.

Find the moment of inertia of a sphere, with respect to an axis through a diameter, in Table 9-1:

$$I = \tfrac{2}{5} mR^2$$

Express the mass of the sphere as a function of its density and radius:

$$m = \tfrac{4}{3}\pi\rho R^3$$

Substitute for m to obtain:

$$I = \tfrac{8}{15}\pi\rho R^5$$

Express the differential of this expression:

$$dI = \tfrac{8}{3}\pi\rho R^4 dR \qquad (1)$$

Express the increase in mass dm as the radius of the sphere increases by dR:

$$dm = 4\pi\,\rho R^2 dR \qquad (2)$$

Eliminate dR between equations (1) and (2) to obtain:

$$dI = \tfrac{2}{3}R^2 dm$$

Integrate over the mass of the spherical shell to obtain:

$$I_{\text{spherical shell}} = \boxed{\tfrac{2}{3}mR^2}$$

54 ••• According to one model, the density of Earth varies with the distance r from the center of Earth as $\rho = C\,[1.22 - (r/R)]$, where R is the radius of Earth and C is a constant. (a) Find C in terms of the total mass M and the radius R. (b) According to this model, what is the moment of inertia of Earth about an axis through its center. (See Problem 53.)

Picture the Problem We can find C in terms of M and R by integrating a spherical shell of mass dm with the given density function to find the mass of Earth as a function of M and then solving for C. In Part (b), we'll start with the moment of inertia of the same spherical shell, substitute Earth's density function, and integrate from 0 to R. Let the axis of rotation be Earth's axis.

(a) Express the mass of Earth using the given density function:

$$M = \int dm = \int_0^R 4\pi\,\rho r^2 dr$$
$$= 4\pi C\int_0^R 1.22r^2 dr - \frac{4\pi C}{R}\int_0^R r^3 dr$$
$$= \frac{4\pi}{3}1.22CR^3 - \pi CR^3$$

Solve for C as a function of M and R to obtain:

$$C = \boxed{0.508\frac{M}{R^3}}$$

(b) From Problem 9-53 we have:

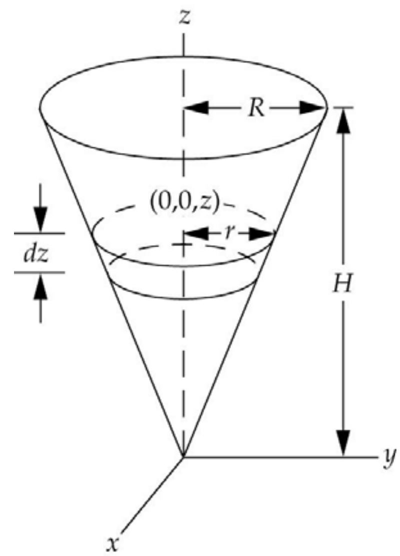
$$dI = \tfrac{8}{3}\pi\,\rho r^4 dr$$

Integrate and simplify to obtain:

$$I = \tfrac{8}{3}\pi\int_0^R \rho r^4 dr = \frac{8\pi(0.508)M}{3R^3}\left[\int_0^R 1.22r^4 dr - \frac{1}{R}\int_0^R r^5 dr\right]$$
$$= \frac{4.26M}{R^3}\left[\frac{1.22}{5}R^5 - \frac{1}{6}R^5\right] = \boxed{0.329MR^2}$$

55 ••• Use integration to determine the moment of inertia about its axis of a uniform right circular cone of height H, base radius R, and mass M.

Picture the Problem Let the origin be at the apex of the cone, with the z axis along the cone's symmetry axis. Then the radius of the elemental ring, at a distance z from the apex, can be obtained from the proportion $\frac{r}{z}=\frac{R}{H}$. The mass dm of the elemental disk is $\rho dV = \rho\pi r^2 dz$. We'll integrate $r^2 dm$ to find the moment of inertia of the disk in terms of R and H and then integrate dm to obtain a second equation in R and H that we can use to eliminate H in our expression for I.



Express the moment of inertia of the cone in terms of the moment of inertia of the elemental disk:

$$I = \tfrac{1}{2}\int r^2 dm$$
$$= \tfrac{1}{2}\int_0^H \frac{R^2}{H^2}z^2\left(\rho\pi\frac{R^2}{H^2}z^2\right)dz$$
$$= \frac{\pi\rho R^4}{2H^4}\int_0^H z^4 dz = \frac{\pi\rho R^4 H}{10}$$

Express the total mass of the cone in terms of the mass of the elemental disk:

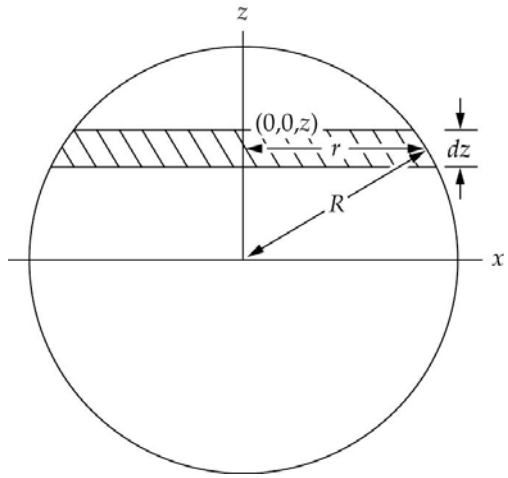
$$M = \pi\rho\int_0^H r^2 dz = \pi\rho\int_0^H \frac{R^2}{H^2}z^2 dz$$
$$= \tfrac{1}{3}\pi\rho R^2 H$$

Divide I by M, simplify, and solve for I to obtain:

$$I = \boxed{\tfrac{3}{10}MR^2}$$

56 ••• Use integration to determine the moment of inertia of a thin uniform disk of mass M and radius R about an axis in the plane of the disk and passing through its center. Check your answer by referring to Table 9-1.

Picture the Problem Let the axis of rotation be the x axis. The radius r of the elemental area is $\sqrt{R^2-z^2}$ and its mass, dm, is $\sigma\, dA = 2\sigma\sqrt{R^2-z^2}\,dz$. We'll integrate $z^2\, dm$ to determine I in terms of σ and then divide this result by M in order to eliminate σ and express I in terms of M and R.



Express the moment of inertia about the x axis: $I = \int z^2 dm = \int z^2 \sigma \, dA$

Substitute for dm to obtain: $$I = \int_{-R}^{R} z^2 \left(2\sigma\sqrt{R^2 - z^2}\, dz\right)$$

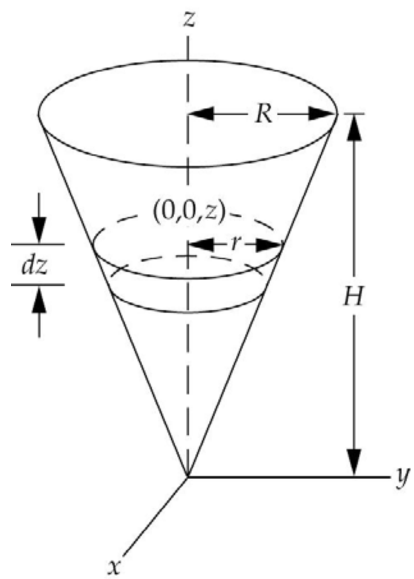
Carrying out the integration yields: $I = \frac{1}{4}\sigma\pi R^4$

The mass of the thin uniform disk is: $M = \sigma\pi R^2$

Divide I by M, simplify, and solve for I to obtain: $I = \boxed{\frac{1}{4}MR^2}$, a result in agreement with the expression given in Table 9-1 for a cylinder of length $L = 0$.

57 ••• An advertising firm has contacted your engineering firm to create a new advertisement for a local ice-cream stand. The owner of this stand wants to add rotating solid cones (painted to look like ice-cream cones, of course) to catch the eye of travelers. Each cone will rotate about an axis parallel to its base and passing through its apex. The actual size of the cones is to be decided upon, and the owner wonders if it would be more energy-efficient to rotate smaller cones than larger ones. He asks your firm to write a report showing the determination of the moment of inertia of a homogeneous right circular cone of height H, base radius R, and mass M. What is the result of your report?

Picture the Problem Choose the coordinate system shown in the diagram below. Then the radius of the elemental disk, at a distance z from the apex, can be obtained from the proportion $\frac{r}{z}=\frac{R}{H}$. The mass dm of the elemental disk is $\rho dV = \rho\pi r^2dz$. Each elemental disk rotates about an axis that is parallel to its diameter but removed from it by a distance z. We can use the result from Problem 9-56 for the moment of inertia of the elemental disk with respect to a diameter and then use the parallel axis theorem to express the moment of inertia of the cone with respect to the x axis.



Using the parallel axis theorem, express the moment of inertia of the elemental disk with respect to the x axis:

$$dI_x = dI_{\text{disk}} + dm\,z^2 \qquad (1)$$

where

$$dm = \rho\,dV = \rho\pi\,r^2dz$$

In Problem 9-56 it was established that the moment of inertia of a thin uniform disk of mass M and radius R rotating about a diameter is $\frac{1}{4}MR^2$. Express this result in terms of our elemental disk:

$$dI_{\text{disk}} = \tfrac{1}{4}\left(\rho\pi\,r^2dz\right)r^2 = \tfrac{1}{4}\rho\pi\left(\frac{R^2}{H^2}z^2\right)^2 dz$$

Substituting for dI_{disk} in equation (1) yields:

$$dI_x = \pi\rho\left[\frac{1}{4}\left(\frac{R^2}{H^2}z^2\right)^2\right]dz + \left(\pi\rho\left(\frac{R}{H}z\right)^2dz\right)z^2$$

Integrate from 0 to H to obtain:

$$I_x = \pi\rho\int_0^H\left[\frac{1}{4}\left(\frac{R^2}{H^2}z^2\right)^2 + \frac{R^2}{H^2}z^4\right]dz$$

$$= \pi\rho\left(\frac{R^4H}{20} + \frac{R^2H^3}{5}\right)$$

Express the total mass of the cone in terms of the mass of the elemental disk:

$$M = \pi\rho\int_0^H r^2 dz = \pi\rho\int_0^H \frac{R^2}{H^2} z^2 dz$$
$$= \tfrac{1}{3}\pi\rho R^2 H$$

Divide I_x by M, simplify, and solve for I_x to obtain:

$$I_x = \boxed{3M\left(\frac{H^2}{5} + \frac{R^2}{20}\right)}$$

Remarks: Because both *H* and *R* appear in the numerator, the larger the cones are, the greater their moment of inertia and the greater the energy consumption required to set them into motion.

Torque, Moment of Inertia, and Newton's Second Law for Rotation

58 • A firm wants to determine the amount of frictional torque in their current line of grindstones, so they can redesign them to be more energy efficient. To do this, they ask you to test the best-selling model, which is basically a disk-shaped grindstone of mass 1.70 kg and radius 8.00 cm which operates at 730 rev/min. When the power is shut off, you time the grindstone and find it takes 31.2 s for it to stop rotating. (*a*) What is the angular acceleration of the grindstone? (Assume constant angular acceleration.) (*b*) What is the frictional torque exerted on the grindstone?

Picture the Problem (*a*) We can use the definition of angular acceleration to find the angular acceleration of the grindstone. (*b*) Applying Newton's second law in rotational form will allow us to find the torque exerted by the friction force acting on the grindstone.

(*a*) From the definition of angular acceleration we have:

$$\alpha = \frac{\Delta\omega}{\Delta t} = \frac{\omega - \omega_0}{\Delta t}$$

or, because $\omega = 0$,

$$\alpha = \frac{-\omega_0}{\Delta t}$$

Substitute numerical values and evaluate α:

$$\alpha = -\frac{730\frac{\text{rev}}{\text{min}} \times \frac{2\pi\,\text{rad}}{\text{rev}} \times \frac{1\,\text{min}}{60\,\text{s}}}{31.2\,\text{s}}$$
$$= \boxed{-2.45\,\text{rad/s}^2}$$

where the minus sign means that the grindstone is slowing down.

(*b*) Use Newton's second law in rotational form to relate the angular acceleration of the grindstone to the frictional torque slowing it:

$$\tau_{\text{frictional}} = -I\alpha$$

Express the moment of inertia of disk with respect to its axis of rotation:

$$I = \tfrac{1}{2}MR^2$$

Substitute for I to obtain:

$$\tau_{\text{frictional}} = -\tfrac{1}{2}MR^2\alpha$$

Substitute numerical values and evaluate $\tau_{\text{frictional}}$:

$$\tau_{\text{frictional}} = -\tfrac{1}{2}(1.70\,\text{kg})(0.0800\,\text{m})^2\left(-2.45\,\text{rad/s}^2\right) = \boxed{0.0133\,\text{N}\cdot\text{m}}$$

59 • **[SSM]** A 2.5-kg 11-cm-radius cylinder, initially at rest, is free to rotate about the axis of the cylinder. A rope of negligible mass is wrapped around it and pulled with a force of 17 N. Assuming that the rope does not slip, find (*a*) the torque exerted on the cylinder by the rope, (*b*) the angular acceleration of the cylinder, and (*c*) the angular speed of the cylinder after 0.50 s.

Picture the Problem We can find the torque exerted by the 17-N force from the definition of torque. The angular acceleration resulting from this torque is related to the torque through Newton's second law in rotational form. Once we know the angular acceleration, we can find the angular speed of the cylinder as a function of time.

(*a*) The torque exerted by the rope is:

$$\tau = F\ell = (17\,\text{N})(0.11\,\text{m}) = 1.87\,\text{N}\cdot\text{m} = \boxed{1.9\,\text{N}\cdot\text{m}}$$

(*b*) Use Newton's second law in rotational form to relate the acceleration resulting from this torque to the torque:

$$\alpha = \frac{\tau}{I}$$

Express the moment of inertia of the cylinder with respect to its axis of rotation:

$$I = \tfrac{1}{2}MR^2$$

Substitute for I and simplify to obtain:

$$\alpha = \frac{2\tau}{MR^2}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{2(1.87\,\text{N}\cdot\text{m})}{(2.5\,\text{kg})(0.11\,\text{m})^2} = 124\,\text{rad/s}^2$$
$$= \boxed{1.2\times10^2\ \text{rad/s}^2}$$

(*c*) Using a constant-acceleration equation, express the angular speed of the cylinder as a function of time:

$$\omega = \omega_0 + \alpha t$$

or, because $\omega_0 = 0$,

$$\omega = \alpha t$$

Substitute numerical values and evaluate ω (0.50 s):

$$\omega(0.50\,\text{s}) = (124\,\text{rad/s}^2)(0.50\,\text{s})$$
$$= \boxed{62\ \text{rad/s}}$$

60 •• A grinding wheel is initially at rest. A constant external torque of 50.0 N·m is applied to the wheel for 20.0 s, giving the wheel an angular speed of 600 rev/min. The external torque is then removed, and the wheel comes to rest 120 s later. Find (*a*) the moment of inertia of the wheel, and (*b*) the frictional torque, which is assumed to be constant.

Picture the Problem We can apply Newton's second law in rotational form to both the speeding up and slowing down motions of the wheel to obtain two equations in *I,* the moment of inertia of the wheel, and τ_{fr}, the frictional torque, that we can solve simultaneously for *I* and τ_{fr}. We'll assume that both the speeding-up and slowing-down of the wheel took place under constant-acceleration conditions.

Apply $\sum\tau = I\alpha$ to the wheel during the speeding-up portion of its motion:

$$\tau_{\text{ext}} - \tau_{\text{fr}} = I\alpha_{\text{speeding up}} \qquad (1)$$

Apply $\sum\tau = I\alpha$ to the wheel during the slowing-down portion of its motion:

$$\tau_{\text{fr}} = I\alpha_{\text{slowing down}} \qquad (2)$$

(*a*) Eliminating τ_{fr} between equations (1) and (2) and solving for *I* yields:

$$I = \frac{\tau_{\text{ext}}}{\alpha_{\text{speeding up}} + \alpha_{\text{slowing down}}}$$

Substituting for $\alpha_{\text{speeding up}}$ and $\alpha_{\text{slowing down}}$ yields:

$$I = \frac{\tau_{\text{ext}}}{\dfrac{\Delta\omega_{\text{speeding up}}}{\Delta t_{\text{speeding up}}} + \dfrac{\Delta\omega_{\text{slowing down}}}{\Delta t_{\text{slowing down}}}}$$

Substitute numerical values and evaluate I:

$$I = \frac{50.0\ \text{N}\cdot\text{m}}{\dfrac{600\dfrac{\text{rev}}{\text{min}}\times\dfrac{2\pi\ \text{rad}}{\text{rev}}\times\dfrac{1\ \text{min}}{60\ \text{s}}}{20.0\ \text{s}} + \dfrac{-600\dfrac{\text{rev}}{\text{min}}\times\dfrac{2\pi\ \text{rad}}{\text{rev}}\times\dfrac{1\ \text{min}}{60\ \text{s}}}{120\ \text{s}}} = 19.10\ \text{kg}\cdot\text{m}^2$$

$$= \boxed{19.1\ \text{kg}\cdot\text{m}^2}$$

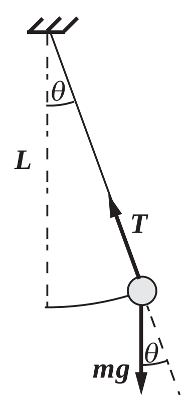
(b) Substitute numerical values in equation (2) and evaluate τ_{fr}:

$$\tau_{\text{fr}} = \left(19.10\ \text{kg}\cdot\text{m}^2\right)\left(\frac{-600\dfrac{\text{rev}}{\text{min}}\times\dfrac{2\pi\ \text{rad}}{\text{rev}}\times\dfrac{1\ \text{min}}{60\ \text{s}}}{120\ \text{s}}\right) = \boxed{-10.0\ \text{N}\cdot\text{m}}$$

where the minus sign is a consequence of the fact that the frictional torque opposes the motion of the wheel.

61 •• A pendulum consisting of a string of length L attached to a bob of mass m swings in a vertical plane. When the string is at an angle θ to the vertical, (a) calculate the tangential acceleration of the bob using $\sum F_{\text{t}} = ma_{\text{t}}$. ($b$) What is the torque exerted about the pivot point? (c) Show that $\sum\tau = I\alpha$ with $a_{\text{t}} = L\alpha$ gives the same tangential acceleration as found in Part (a).

Picture the Problem The pendulum and the forces acting on it are shown in the free-body diagram. Note that the tension in the string is radial, and so exerts no tangential force on the ball. We can use Newton's second law in both translational and rotational form to find the tangential component of the acceleration of the bob.



(a) Referring to the free-body diagram, express the component of $m\vec{g}$ that is tangent to the circular path of the bob:

$$F_{\text{t}} = mg\sin\theta$$

Use Newton's second law to express the tangential acceleration of the bob:

$$a_{\text{t}} = \frac{F_{\text{t}}}{m} = \frac{mg\sin\theta}{m} = \boxed{g\sin\theta}$$

(*b*) Noting that, because the line-of-action of the tension passes through the pendulum's pivot point, its lever arm is zero and the net torque is due to the weight of the bob, sum the torques about the pivot point to obtain:

$$\sum \tau_{\text{pivot point}} = \boxed{mgL\sin\theta}$$

(*c*) Use Newton's second law in rotational form to relate the angular acceleration of the pendulum to the net torque acting on it:

$$\tau_{\text{net}} = mgL\sin\theta = I\alpha$$

Solve for α to obtain:

$$\alpha = \frac{mgL\sin\theta}{I}$$

Express the moment of inertia of the bob with respect to the pivot point:

$$I = mL^2$$

Substitute for I and simplify to obtain:

$$\alpha = \frac{mgL\sin\theta}{mL^2} = \frac{g\sin\theta}{L}$$

Relate α to a_t, substitute for α, and simplify to obtain:

$$a_t = r\alpha = L\left(\frac{g\sin\theta}{L}\right) = \boxed{g\sin\theta}$$

62 **•••** A uniform rod of mass M and length L is pivoted at one end and hangs as in Figure 9-51 so that it is free to rotate without friction about its pivot. It is struck a sharp horizontal blow a distance x below the pivot, as shown. (*a*) Show that, just after the rod is struck, the speed of the center of mass of the rod is given by $v_0 = 3xF_0\Delta t/(2ML)$, where F_0 and Δt are the average force and duration, respectively, of the blow. (*b*) Find the horizontal component of the force exerted by the pivot on the rod, and show that this force component is zero if $x = \frac{2}{3}L$. This point (the point of impact when the horizontal component of the pivot force is zero) is called the *center of percussion* of the rod-pivot system.

Picture the Problem We can express the velocity of the center of mass of the rod in terms of its distance from the pivot point and the angular speed of the rod. We can find the angular speed of the rod by using Newton's second law to find its angular acceleration and then a constant-acceleration equation that relates ω to α. We'll use the impulse-momentum relationship to derive the expression for the force delivered to the rod by the pivot. Finally, the location of the *center of percussion* of the rod will be verified by setting the force exerted by the pivot to zero.

(*a*) Relate the velocity of the center of mass to its distance from the pivot point:

$$v_{cm} = \frac{L}{2}\omega \qquad (1)$$

Express the torque due to F_0:

$$\tau = F_0 x = I_{pivot}\alpha \Rightarrow \alpha = \frac{F_0 x}{I_{pivot}}$$

Express the moment of inertia of the rod with respect to an axis through its pivot point:

$$I_{pivot} = \tfrac{1}{3}ML^2$$

Substitute for I_{pivot} and simplify to obtain:

$$\alpha = \frac{3F_0 x}{ML^2}$$

Express the angular speed of the rod in terms of its angular acceleration:

$$\omega = \alpha\,\Delta t = \frac{3F_0 x\Delta t}{ML^2}$$

Substitute in equation (1) to obtain:

$$v_{cm} = \boxed{\frac{3F_0 x\Delta t}{2ML}}$$

(*b*) Let I_P be the impulse exerted by the pivot on the rod. Then the total impulse (equal to the change in momentum of the rod) exerted on the rod is:

$$I_P + F_0\Delta t = Mv_{cm}$$

and

$$I_P = Mv_{cm} - F_0\Delta t$$

Substitute your result from (*a*) to obtain:

$$I_P = \frac{3F_0 x\Delta t}{2L} - F_0\Delta t = F_0\Delta t\left(\frac{3x}{2L} - 1\right)$$

Because $I_P = F_P\Delta t$:

$$F_P = \boxed{F_0\left(\frac{3x}{2L} - 1\right)}$$

If F_P is zero, then:

$$\frac{3x}{2L} - 1 = 0 \Rightarrow x = \boxed{\frac{2L}{3}}$$

63 ••• A uniform horizontal disk of mass M and radius R is spinning about the vertical axis through its center with an angular speed ω. When the spinning disk is dropped onto a horizontal tabletop, kinetic-frictional forces on the disk oppose its spinning motion. Let μ_k be the coefficient of kinetic friction between the disk and the tabletop. (*a*) Find the torque $d\tau$ exerted by the force of friction

on a circular element of radius r and width dr. (b) Find the total torque exerted by friction on the disk. (c) Find the time required for the disk to stop rotating.

Picture the Problem We'll first express the torque exerted by the force of friction on the elemental disk and then integrate this expression to find the torque on the entire disk. We'll use Newton's second law to relate this torque to the angular acceleration of the disk and then to the stopping time for the disk.

(a) Express the torque exerted on the elemental disk in terms of the friction force and the distance to the elemental disk:

$$d\tau_{\mathrm{f}} = r\,df_{\mathrm{k}} \quad (1)$$

Using the definition of the coefficient of friction, relate the force of friction to μ_{k} and the weight of the circular element:

$$df_{\mathrm{k}} = \mu_{\mathrm{k}}\,g\,dm \quad (2)$$

Letting σ represent the mass per unit area of the disk, express the mass of the circular element:

$$dm = 2\pi r\sigma\,dr \quad (3)$$

Substitute equations (2) and (3) in (1) to obtain:

$$d\tau_{\mathrm{f}} = 2\pi\mu_{\mathrm{k}}\sigma g r^2 dr \quad (4)$$

Because $\sigma = \dfrac{M}{\pi R^2}$:

$$d\tau_{\mathrm{f}} = \boxed{\frac{2\mu_{\mathrm{k}} M g}{R^2} r^2 dr}$$

(b) Integrate $d\tau_{\mathrm{f}}$ to obtain the total torque on the elemental disk:

$$\tau_{\mathrm{f}} = \frac{2\mu_{\mathrm{k}} M g}{R^2}\int_0^R r^2 dr = \boxed{\tfrac{2}{3} MR\mu_{\mathrm{k}} g}$$

(c) Relate the disk's stopping time to its angular speed and acceleration:

$$\Delta t = \frac{\omega}{\alpha}$$

Using Newton's second law, express α in terms of the net torque acting on the disk:

$$\alpha = \frac{\tau_{\mathrm{f}}}{I}$$

Substituting for α yields:

$$\Delta t = \frac{\omega}{\frac{\tau_{\mathrm{f}}}{I}} = \frac{I\omega}{\tau_{\mathrm{f}}}$$

The moment of inertia of the disk, with respect to its axis of rotation, is:

$$I = \tfrac{1}{2}MR^2$$

Substitute for I and τ_f (from Part (a)) and simplify to obtain:

$$\Delta t = \frac{\tfrac{1}{2}MR^2\omega}{\tfrac{2}{3}MR\mu_k g} = \boxed{\frac{3R\omega}{4\mu_k g}}$$

Energy Methods Including Rotational Kinetic Energy

64 • The particles in Figure 9-52 are connected by a very light rod. They rotate about the y axis at 2.0 rad/s. (a) Find the speed of each particle, and use it to calculate the kinetic energy of this system directly from $\sum \tfrac{1}{2}m_i v_i^2$. (b) Find the moment of inertia about the y axis, calculate the kinetic energy from $K = \tfrac{1}{2}I\omega^2$, and compare your result with your Part-(a) result.

Picture the Problem The kinetic energy of this rotating system of particles can be calculated either by finding the tangential velocities of the particles and using these values to find the kinetic energy or by finding the moment of inertia of the system and using the expression for the rotational kinetic energy of a system.

(a) Use the relationship between v and ω to find the speed of each particle:

$$v_3 = r_3\omega = (0.20\,\text{m})(2.0\,\text{rad/s}) = 0.40\,\text{m/s}$$

and

$$v_1 = r_1\omega = (0.40\,\text{m})(2.0\,\text{rad/s}) = 0.80\,\text{m/s}$$

The kinetic energy of the system is:

$$K = 2K_3 + 2K_1 = m_3v_3^2 + m_1v_1^2$$

Substitute numerical values and evaluate K:

$$K = (3.0\,\text{kg})(0.40\,\text{m/s})^2 + (1.0\,\text{kg})(0.80\,\text{m/s})^2 = \boxed{1.1\,\text{J}}$$

(b) Use the definition of the moment of inertia of a system of particles to obtain:

$$I = \sum_i m_i r_i^2 = m_1r_1^2 + m_2r_2^2 + m_3r_3^2 + m_4r_4^2$$

Substitute numerical values and evaluate I:

$$I = (1.0\,\text{kg})(0.40\,\text{m})^2 + (3.0\,\text{kg})(0.20\,\text{m})^2 + (1.0\,\text{kg})(0.40\,\text{m})^2 + (3.0\,\text{kg})(0.20\,\text{m})^2 = 0.560\,\text{kg}\cdot\text{m}^2$$

The kinetic energy of the system of particles is given by:

$$K = \tfrac{1}{2}I\omega^2$$

Substitute numerical values and evaluate K:

$$K = \tfrac{1}{2}\left(0.560\,\text{kg}\cdot\text{m}^2\right)\left(2.0\,\text{rad/s}\right)^2 = \boxed{1.1\,\text{J}}$$

in agreement with our Part (*a*) result.

65 • [SSM] A 1.4-kg 15-cm-diameter solid sphere is rotating about its diameter at 70 rev/min. (*a*) What is its kinetic energy? (*b*) If an additional 5.0 mJ of energy are added to the kinetic energy, what is the new angular speed of the sphere?

Picture the Problem We can find the kinetic energy of this rotating ball from its angular speed and its moment of inertia. In Part (*b*) we can use the work-kinetic energy theorem to find the angular speed of the sphere when additional kinetic energy has been added to the sphere.

(*a*) The initial rotational kinetic energy of the ball is:

$$K_\text{i} = \tfrac{1}{2}I\omega_\text{i}^2$$

Express the moment of inertia of the ball with respect to its diameter:

$$I = \tfrac{2}{5}MR^2$$

Substitute for I to obtain:

$$K_\text{i} = \tfrac{1}{5}MR^2\omega_\text{i}^2$$

Substitute numerical values and evaluate K:

$$K_\text{i} = \tfrac{1}{5}(1.4\,\text{kg})(0.075\,\text{m})^2\left(70\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}\right)^2 = 84.6\,\text{mJ} = \boxed{85\,\text{mJ}}$$

(*b*) Apply the work-kinetic energy theorem to the sphere to obtain:

$$W = \Delta K = K_\text{f} - K_\text{i}$$

or

$$W = \tfrac{1}{2}I\omega_\text{f}^2 - K_\text{i} \Rightarrow \omega_\text{f} = \sqrt{\frac{2(W+K_\text{i})}{I}}$$

Substitute for I and simplify to obtain:

$$\omega_\text{f} = \sqrt{\frac{2(W+K_\text{i})}{\frac{2}{5}MR^2}} = \sqrt{\frac{5(W+K_\text{i})}{MR^2}}$$

Substitute numerical values and evaluate ω_f:

$$\omega_f = \sqrt{\frac{5(84.6\text{ mJ} + 5.0\text{ mJ})}{(1.4\text{ kg})(7.5\text{ cm})^2}}$$
$$= 7.542\frac{\text{rad}}{\text{s}} \times \frac{1\text{ rev}}{2\pi\text{ rad}} \times \frac{60\text{ s}}{\text{min}}$$
$$= \boxed{72\text{ rev/min}}$$

66 •• Calculate the kinetic energy of Earth due to its spinning about its axis, and compare your answer with the kinetic energy of the orbital motion of Earth's center of mass about the Sun. Assume Earth to be a homogeneous sphere of mass 6.0×10^{24} kg and radius 6.4×10^6 m. The radius of Earth's orbit is 1.5×10^{11} m.

Picture the Problem Earth's rotational kinetic energy is given by $K_{\text{rot}} = \frac{1}{2}I\omega^2$ where I is its moment of inertia with respect to its axis of rotation. The center of mass of the Earth-Sun system is so close to the center of the Sun and the Earth-Sun distance so large that we can use the Earth-Sun distance as the separation of their centers of mass and assume each to be a point mass.

Express the rotational kinetic energy of Earth:

$$K_{\text{rot}} = \tfrac{1}{2}I\omega^2 \quad (1)$$

Find the angular speed of Earth's rotation using the definition of ω:

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{2\pi\text{ rad}}{24\text{ h} \times \frac{3600\text{ s}}{\text{h}}}$$
$$= 7.27 \times 10^{-5}\text{ rad/s}$$

From Table 9-1, for the moment of inertia of a homogeneous sphere, we find:

$$I = \tfrac{2}{5}MR^2$$
$$= \tfrac{2}{5}(6.0 \times 10^{24}\text{ kg})(6.4 \times 10^6\text{ m})^2$$
$$= 9.83 \times 10^{37}\text{ kg}\cdot\text{m}^2$$

Substitute numerical values in equation (1) to obtain:

$$K_{\text{rot}} = \tfrac{1}{2}(9.83 \times 10^{37}\text{ kg}\cdot\text{m}^2)$$
$$\times (7.27 \times 10^{-5}\text{ rad/s})^2$$
$$= 2.60 \times 10^{29}\text{ J} = \boxed{2.6 \times 10^{29}\text{ J}}$$

Earth's orbital kinetic energy is:

$$K_{\text{orb}} = \tfrac{1}{2}I\omega_{\text{orb}}^2 \quad (2)$$

Find the angular speed of the center of mass of the Earth-Sun system:

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{2\pi\,\text{rad}}{365.24\,\text{days} \times 24\,\frac{\text{h}}{\text{day}} \times \frac{3600\,\text{s}}{\text{h}}} = 1.99 \times 10^{-7}\ \text{rad/s}$$

The orbital moment of inertia of Earth is:

$$I = M_E R_{\text{orb}}^2 = \left(6.0 \times 10^{24}\ \text{kg}\right)\left(1.50 \times 10^{11}\ \text{m}\right)^2 = 1.35 \times 10^{47}\,\text{kg}\cdot\text{m}^2$$

Substitute for I in equation (2) and evaluate K_{orb}:

$$K_{\text{orb}} = \tfrac{1}{2}\left(1.35 \times 10^{47}\ \text{kg}\cdot\text{m}^2\right) \times \left(1.99 \times 10^{-7}\ \text{rad/s}\right)^2 = 2.68 \times 10^{33}\ \text{J}$$

Evaluate the ratio $\frac{K_{\text{orb}}}{K_{\text{rot}}}$:

$$\frac{K_{\text{orb}}}{K_{\text{rot}}} = \frac{2.68 \times 10^{33}\ \text{J}}{2.60 \times 10^{29}\ \text{J}} \approx \boxed{10^4}$$

67 •• [SSM] A 2000-kg block is lifted at a constant speed of 8.0 cm/s by a steel cable that passes over a massless pulley to a motor-driven winch (Figure 9-53). The radius of the winch drum is 30 cm. (*a*) What is the tension in the cable? (*b*) What torque does the cable exert on the winch drum? (*c*) What is the angular speed of the winch drum? (*d*) What power must be developed by the motor to drive the winch drum?

Picture the Problem Because the load is not being accelerated, the tension in the cable equals the weight of the load. The role of the massless pulley is to change the direction the force (tension) in the cable acts.

(*a*) Because the block is lifted at constant speed:

$$T = mg = \left(2000\,\text{kg}\right)\left(9.81\,\text{m/s}^2\right) = \boxed{19.6\,\text{kN}}$$

(*b*) Apply the definition of torque of the winch drum:

$$\tau = Tr = \left(19.6\,\text{kN}\right)\left(0.30\,\text{m}\right) = \boxed{5.9\,\text{kN}\cdot\text{m}}$$

(*c*) Relate the angular speed of the winch drum to the rate at which the load is being lifted (the tangential speed of the cable on the drum):

$$\omega = \frac{v}{r} = \frac{0.080\,\text{m/s}}{0.30\,\text{m}} = \boxed{0.27\,\text{rad/s}}$$

(*d*) The power developed by the motor in terms is the product of the tension in the cable and the speed with which the load is being lifted:

$$P = Tv = (19.6\,\text{kN})(0.080\,\text{m/s}) = \boxed{1.6\,\text{kW}}$$

68 •• A uniform disk that has a mass *M* and a radius *R* can rotate freely about a fixed horizontal axis that passes through its center and is perpendicular to the plane of the disk. A small particle that has a mass *m* is attached to the rim of the disk at the top, directly above the pivot. The system is gently nudged, and the disk begins to rotate. As the particle passes through its lowest point, (*a*) what is the angular speed of the disk, and (*b*) what force is exerted by the disk on the particle?

Picture the Problem Let the zero of gravitational potential energy be at the lowest point of the small particle. We can use conservation of energy to find the angular speed of the disk when the particle is at its lowest point and Newton's second law to find the force the disk will have to exert on the particle to keep it from falling off.

(*a*) Use conservation of energy to relate the initial potential energy of the system to its rotational kinetic energy when the small particle is at its lowest point:

$$\Delta K + \Delta U = 0$$

or, because $U_f = K_i = 0$,

$$\tfrac{1}{2}\left(I_{\text{disk}} + I_{\text{particle}}\right)\omega_f^2 - mg\Delta h = 0$$

Solving for ω_f yields:

$$\omega_f = \sqrt{\frac{2mg\Delta h}{I_{\text{disk}} + I_{\text{particle}}}}$$

Substitute for I_{disk}, I_{particle}, and Δh and simplify to obtain:

$$\omega_f = \sqrt{\frac{2mg(2R)}{\frac{1}{2}MR^2 + mR^2}} = \boxed{\sqrt{\frac{8mg}{R(2m+M)}}}$$

(*b*) The mass is in uniform circular motion at the bottom of the disk, so the sum of the force *F* exerted by the disk and the gravitational force must be the centripetal force:

$$F - mg = mR\omega_f^2 \Rightarrow F = mg + mR\omega_f^2$$

Substituting for ω_f^2 and simplifying yields::

$$F = mg + mR\left(\frac{8mg}{R(2m+M)}\right)$$
$$= \boxed{mg\left(1+\frac{8m}{2m+M}\right)}$$

69 •• A uniform 1.5-m-diameter ring is pivoted at a point on its perimeter so that it is free to rotate about a horizontal axis that is perpendicular to the plane of the ring. The ring is released with the center of the ring at the same height as the axis (Figure 9-54). (*a*) If the ring was released from rest, what was its maximum angular speed? (*b*) What minimum angular speed must it be given at release if it is to rotate a full 360°?

Picture the Problem Let the zero of gravitational potential energy be at the center of mass of the ring when it is directly below the point of support. We'll use conservation of energy to relate the maximum angular speed and the initial angular speed required for a complete revolution to the changes in the potential energy of the ring.

(*a*) Use conservation of energy to relate the initial potential energy of the ring to its rotational kinetic energy when its center of mass is directly below the point of support:

$$\Delta K + \Delta U = 0$$

or, because $U_f = K_i = 0$,

$$\tfrac{1}{2}I_P\omega_{max}^2 - mg\Delta h = 0 \qquad (1)$$

Use the parallel axis theorem and Table 9-1 to express the moment of inertia of the ring with respect to its pivot point P:

$$I_P = I_{cm} + mR^2$$

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}\left(mR^2 + mR^2\right)\omega_{max}^2 - mgR = 0$$

Solving for ω_{max} yields:

$$\omega_{max} = \sqrt{\frac{g}{R}}$$

Substitute numerical values and evaluate ω_{max}:

$$\omega_{max} = \sqrt{\frac{9.81\,\text{m/s}^2}{0.75\,\text{m}}} = \boxed{3.6\,\text{rad/s}}$$

(*b*) Use conservation of energy to relate the final potential energy of the ring to its initial rotational kinetic energy:

$$\Delta K + \Delta U = 0$$

or, because $U_i = K_f = 0$,

$$-\tfrac{1}{2}I_P\omega_i^2 + mg\Delta h = 0$$

Noting that the center of mass must rise a distance R if the ring is to make a complete revolution, substitute for I_P and Δh to obtain:

$$-\tfrac{1}{2}\left(mR^2 + mR^2\right)\omega_i^2 + mgR = 0$$

Solving for ω_i yields:

$$\omega_i = \sqrt{\frac{g}{R}}$$

Substitute numerical values and evaluate ω_i:

$$\omega_i = \sqrt{\frac{9.81\,\text{m/s}^2}{0.75\,\text{m}}} = \boxed{3.6\,\text{rad/s}}$$

70 •• You set out to design a car that uses the energy stored in a flywheel consisting of a uniform 100-kg cylinder of radius R that has a maximum angular speed of 400 rev/s. The flywheel must deliver an average of 2.00 MJ of energy for each kilometer of distance. Find the smallest value of R for which the car can travel 300 km without the flywheel needing to be reenergized.

Picture the Problem We can find the energy that must be stored in the flywheel and relate this energy to the radius of the wheel and use the definition of rotational kinetic energy to find the wheel's radius.

Relate the kinetic energy of the flywheel to the energy it must deliver:

$$K_{\text{rot}} = \tfrac{1}{2} I_{\text{cyl}}\omega^2$$

Express the moment of inertia of the flywheel:

$$I_{\text{cyl}} = \tfrac{1}{2} MR^2$$

Substitute for I_{cyl} to obtain:

$$K_{\text{rot}} = \tfrac{1}{2}\left(\tfrac{1}{2} MR^2\right)\omega^2 \Rightarrow R = \frac{2}{\omega}\sqrt{\frac{K_{\text{rot}}}{M}}$$

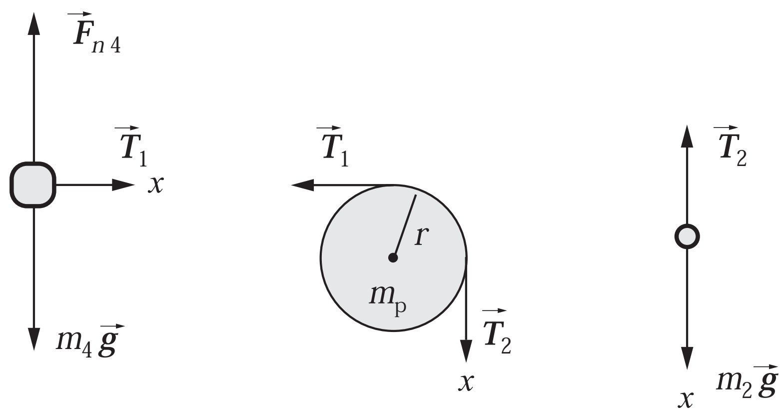
Substitute numerical values and evaluate R:

$$R = \frac{2}{400\,\frac{\text{rev}}{\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}}}\sqrt{\frac{\left(2.00\,\frac{\text{MJ}}{\text{km}}\right)(300\,\text{km})}{100\,\text{kg}}} = \boxed{1.95\,\text{m}}$$

Pulleys, Yo-Yos, and Hanging Things

71 •• [SSM] The system shown in Figure 9-55consists of a 4.0-kg block resting on a frictionless horizontal ledge. This block is attached to a string that passes over a pulley, and the other end of the string is attached to a hanging 2.0-kg block. The pulley is a uniform disk of radius 8.0 cm and mass 0.60 kg. Find the acceleration of each block and the tension in the string.

Picture the Problem The diagrams show the forces acting on each of the masses and the pulley. We can apply Newton's second law to the two blocks and the pulley to obtain three equations in the unknowns T_1, T_2, and a.



Apply Newton's second law to the two blocks and the pulley:

$$\sum F_x = T_1 = m_4 a\,, \qquad (1)$$

$$\sum \tau_p = (T_2 - T_1)r = I_p\alpha\,, \qquad (2)$$

and

$$\sum F_x = m_2 g - T_2 = m_2 a \qquad (3)$$

Substitute for I_p and α in equation (2) to obtain:

$$T_2 - T_1 = \tfrac{1}{2}M_p a \qquad (4)$$

Eliminate T_1 and T_2 between equations (1), (3) and (4) and solve for a:

$$a = \frac{m_2 g}{m_2 + m_4 + \frac{1}{2}M_p}$$

Substitute numerical values and evaluate a:

$$a = \frac{(2.0\,\text{kg})(9.81\,\text{m/s}^2)}{2.0\,\text{kg} + 4.0\,\text{kg} + \frac{1}{2}(0.60\,\text{kg})} = 3.11\,\text{m/s}^2 = \boxed{3.1\,\text{m/s}^2}$$

Using equation (1), evaluate T_1:

$$T_1 = (4.0\,\text{kg})(3.11\,\text{m/s}^2) = \boxed{12\,\text{N}}$$

Solve equation (3) for T_2:

$$T_2 = m_2(g - a)$$

Substitute numerical values and evaluate T_2:

$$T_2 = (2.0\,\text{kg})(9.81\,\text{m/s}^2 - 3.11\,\text{m/s}^2) = \boxed{13\,\text{N}}$$

72 •• For the system in Problem 71, the 2.0-kg block is released from rest. (*a*) Find the speed of the block after it falls a distance of 2.5 m. (*b*) What is the angular speed of the pulley at this instant?

Picture the Problem We'll solve this problem for the general case in which the mass of the block on the ledge is M, the mass of the hanging block is m, and the mass of the pulley is M_p, and R is the radius of the pulley. Let the zero of gravitational potential energy be 2.5 m below the initial position of the 2.0-kg block and R represent the radius of the pulley. Let the system include both blocks, the shelf and pulley, and Earth. The initial potential energy of the 2.0-kg block will be transformed into the translational kinetic energy of both blocks plus rotational kinetic energy of the pulley.

(*a*) Use energy conservation to relate the speed of the 2 kg block when it has fallen a distance Δh to its initial potential energy and the kinetic energy of the system:

$$\Delta K + \Delta U = 0$$

or, because $K_\text{i} = U_\text{f} = 0$,

$$\tfrac{1}{2}(m+M)v^2 + \tfrac{1}{2}I_\text{pulley}\omega^2 - mgh = 0$$

Substitute for I_pulley and ω to obtain:

$$\tfrac{1}{2}(m+M)v^2 + \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\frac{v^2}{R^2} - mgh = 0$$

Solving for v yields:

$$v = \sqrt{\frac{2mgh}{M + m + \frac{1}{2}M_p}}$$

Substitute numerical values and evaluate v:

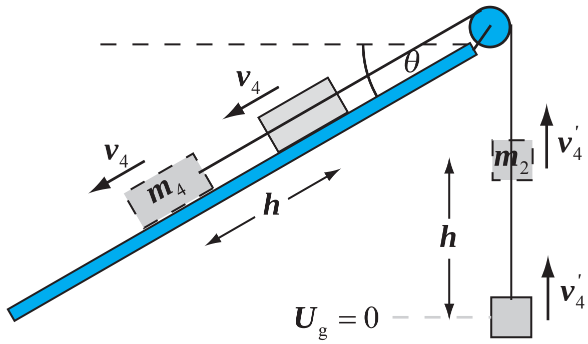
$$v = \sqrt{\frac{2(2.0\,\text{kg})(9.81\,\text{m/s}^2)(2.5\,\text{m})}{4.0\,\text{kg} + 2.0\,\text{kg} + \frac{1}{2}(0.60\,\text{kg})}} = 3.946\,\text{m/s} = \boxed{3.9\,\text{m/s}}$$

(*b*) The angular speed of the pulley is the ratio of its tangential speed to its radius:

$$\omega = \frac{v}{R} = \frac{3.946\,\text{m/s}}{0.080\,\text{m}} = \boxed{49\,\text{rad/s}}$$

73 •• For the system in Problem 71, if the (frictionless) ledge were adjustable in angle, at what angle would it have to be tilted upward so that once the system is set into motion the blocks will continue to move at constant speed?

Picture the Problem The pictorial representation shows the ledge with its left end lowered and the 4.0-kg block moving with a constant speed v_4. As this block (whose mass is m_4) slides down the frictionless incline, the block whose mass is m_2 rises. Let the system include Earth, the ledge, the pulley and both blocks and apply conservation of mechanical energy to determine the angle of inclination of the ledge.



Apply conservation of mechanical energy to the two moving objects to obtain:

$$\Delta K_2 + \Delta K_4 + \Delta K_{\text{pulley}} + \Delta U_2 + \Delta U_4 = 0$$

Because the objects are moving at constant speed, $\Delta K_2 = \Delta K_4 = \Delta K_{\text{pulley}} = 0$ and:

$$\Delta U_2 + \Delta U_4 = 0$$

Substituting for ΔU_2 and ΔU_4 yields:

$$m_2 gh - m_4 gh \sin\theta = 0$$

Solving for θ yields:

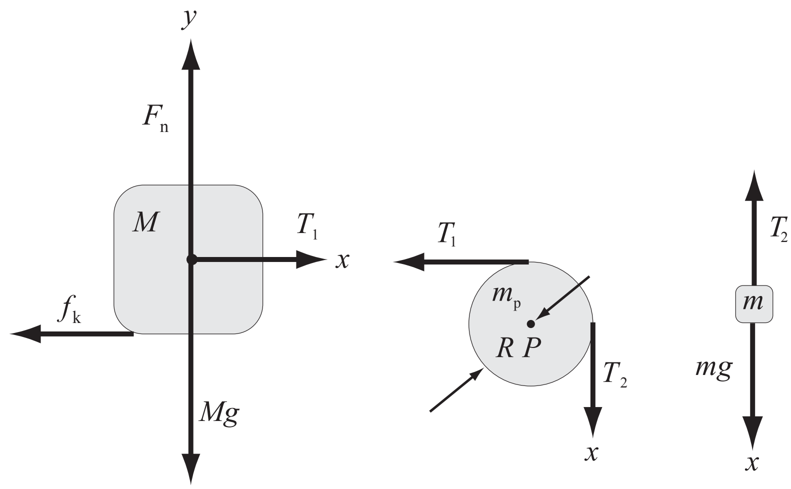
$$\theta = \sin^{-1}\left(\frac{m_2}{m_4}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left(\frac{2.0\,\text{kg}}{4.0\,\text{kg}}\right) = \boxed{30^\circ}$$

74 •• In the system shown in Figure 9-55, there is a 4.0-kg block resting on a horizontal ledge. The coefficient of kinetic friction between the ledge and the block is 0.25. The block is attached to a string that passes over a pulley and the other end of the string is attached to a hanging 2.0-kg block. The pulley is a uniform disk of radius 8.0 cm and mass 0.60 kg. Find the acceleration of each block and the tensions in the segments of string attached to each block.

Picture the Problem Assuming that the string does not stretch or slip on the pulley, we can apply Newton's second law in translational form to the both the 4.0-kg block and the 2.0-kg block and Newton's second law in rotational form to the pulley to obtain simultaneous equations in the tensions T_1 and T_2 in the string and the common acceleration a of the blocks.



Apply $\sum\vec{F} = m\vec{a}$ to the block whose mass is M:

$$\sum F_x = T_1 - f_k = Ma \qquad (1)$$

and

$$\sum F_y = F_n - Mg = 0 \Rightarrow F_n = Mg$$

Because $f_k = \mu_k F_n$ and $F_n = Mg$, equation (1) becomes:

$$T_1 - \mu_k Mg = Ma$$

or

$$T_1 = Ma + \mu_k Mg = M(a + \mu_k g) \qquad (2)$$

Apply $\sum\vec{F} = m\vec{a}$ to the block whose mass is m:

$$\sum F_x = mg - T_2 = ma$$

or

$$T_2 = mg - ma = m(g - a) \qquad (3)$$

Apply $\sum\tau = I_P\alpha$ to the pulley:

$$T_2R - T_1R = I_P\alpha$$

or, because $\alpha = a/R$,

$$T_2R - T_1R = I_P\frac{a}{R}$$

Substituting for I_p (see Table 9-1) and simplifying gives:

$$T_2R - T_1R = \tfrac{1}{2}m_P R^2\left(\frac{a}{R}\right)$$

and

$$T_2 - T_1 = \tfrac{1}{2}m_P a$$

Substituting for T_2 (from equation (3)) and T_1 (from equation (2)) yields:

$$mg - ma - Ma - \mu_k Mg = \tfrac{1}{2} m_p a$$

Solving for a yields:

$$a = \frac{(m - \mu_k M)g}{m + M + \frac{1}{2} m_p}$$

Substitute numerical values and evaluate a:

$$a = \frac{(2.0\text{ kg} - (0.25)(4.0\text{ kg}))(9.81\text{ m/s}^2)}{2.0\text{ kg} + 4.0\text{ kg} + \frac{1}{2}(0.60\text{ kg})}$$
$$= 1.56\text{ m/s}^2 = \boxed{1.6\text{ m/s}^2}$$

Substitute numerical values in equation (2) and evaluate T_1:

$$T_1 = (4.0\text{ kg})\left[1.56\text{ m/s}^2 + (0.25)(9.81\text{ m/s}^2)\right] = 16.04\text{ N} = \boxed{16\text{ N}}$$

Substitute numerical values in equation (3) and evaluate T_2:

$$T_2 = (2.0\text{ kg})(9.81\text{ m/s}^2 - 1.56\text{ m/s}^2) = \boxed{17\text{ N}}$$

75 •• A 1200-kg car is being raised over water by a winch. At the moment the car is 5.0 m above the water (Figure 9-56), the gearbox breaks—allowing the winch drum to spin freely as the car falls. During the car's fall, there is no slipping between the (massless) rope, the pulley wheel, and the winch drum. The moment of inertia of the winch drum is 320 kg·m^2, and the moment of inertia of the pulley wheel is 4.00 kg·m^2. The radius of the winch drum is 0.800 m, and the radius of the pulley is 0.300 m. Assume the car starts to fall from rest. Find the speed of the car as it hits the water.

Picture the Problem Let the zero of gravitational potential energy be at the water's surface and let the system include the winch, the car, and Earth. We'll apply conservation of energy to relate the car's speed as it hits the water to its initial potential energy. Note that some of the car's initial potential energy will be transformed into rotational kinetic energy of the winch and pulley.

Use conservation of mechanical energy to relate the car's speed as it hits the water to its initial potential energy:

$$\Delta K + \Delta U = 0$$
or, because $K_i = U_f = 0$,
$$\tfrac{1}{2} mv^2 + \tfrac{1}{2} I_w \omega_w^2 + \tfrac{1}{2} I_p \omega_p^2 - mg\Delta h = 0$$

Express ω_w^2 and ω_p^2 in terms of the speed v of the rope, which is the same throughout the system:

$$\omega_w^2=\frac{v^2}{r_w^2}\text{ and }\omega_p^2=\frac{v^2}{r_p^2}$$

Substitute for ω_w^2 and ω_p^2 to obtain:

$$\tfrac{1}{2}mv^2+\tfrac{1}{2}I_w\frac{v^2}{r_w^2}+\tfrac{1}{2}I_p\frac{v^2}{r_p^2}-mg\Delta h=0$$

Solving for v yields:

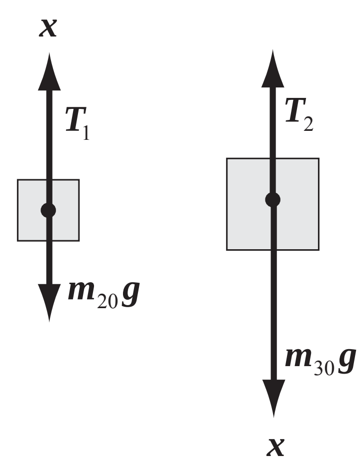
$$v=\sqrt{\frac{2mg\Delta h}{m+\dfrac{I_w}{r_w^2}+\dfrac{I_p}{r_p^2}}}$$

Substitute numerical values and evaluate v:

$$v=\sqrt{\frac{2(1200\,\text{kg})(9.81\,\text{m/s}^2)(5.00\,\text{m})}{1200\,\text{kg}+\dfrac{320\,\text{kg}\cdot\text{m}^2}{(0.800\,\text{m})^2}+\dfrac{4.00\,\text{kg}\cdot\text{m}^2}{(0.300\,\text{m})^2}}}=\boxed{8.21\,\text{m/s}}$$

76 •• The system in Figure 9-57 is released from rest when the 30-kg block is 2.0 m above the ledge. The pulley is a uniform 5.0-kg disk with a radius of 10 cm. Just before the 30-kg block hits the ledge, find (*a*) its speed, (*b*) the angular speed of the pulley, and (*c*) the tensions in the strings. (*d*) Find the time of descent for the 30-kg block. Assume that the string does not slip on the pulley.

Picture the Problem Let the system include the blocks, the pulley and Earth. Choose the zero of gravitational potential energy to be at the ledge and apply energy conservation to relate the impact speed of the 30-kg block to the initial potential energy of the system. We can use a constant-acceleration equations and Newton's second law to find the tensions in the strings and the descent time.



(*a*) Use conservation of mechanical energy to relate the impact speed of the 30-kg block to the initial potential energy of the system:

$$\Delta K+\Delta U=0$$

or, because $K_i = U_f = 0$,

$$\tfrac{1}{2}m_{30}v^2+\tfrac{1}{2}m_{20}v^2+\tfrac{1}{2}I_p\omega_p^2+m_{20}g\Delta h-m_{30}g\Delta h=0$$

Substitute for ω_p and I_p to obtain:

$$\tfrac{1}{2}m_{30}v^2+\tfrac{1}{2}m_{20}v^2+\tfrac{1}{2}\left(\tfrac{1}{2}M_pr^2\right)\left(\frac{v^2}{r^2}\right)+m_{20}g\Delta h-m_{30}g\Delta h=0$$

Solving for v yields:

$$v=\sqrt{\frac{2g\Delta h(m_{30}-m_{20})}{m_{20}+m_{30}+\tfrac{1}{2}M_p}}$$

Substitute numerical values and evaluate v:

$$v=\sqrt{\frac{2(9.81\,\text{m/s}^2)(2.0\,\text{m})(30\,\text{kg}-20\,\text{kg})}{20\,\text{kg}+30\,\text{kg}+\tfrac{1}{2}(5.0\,\text{kg})}}=2.73\,\text{m/s}=\boxed{2.7\,\text{m/s}}$$

(*b*) Find the angular speed at impact from the tangential speed at impact and the radius of the pulley:

$$\omega=\frac{v}{r}=\frac{2.73\,\text{m/s}}{0.10\,\text{m}}=\boxed{27\,\text{rad/s}}$$

(*c*) Apply Newton's second law to the blocks:

$$\sum F_x=T_1-m_{20}g=m_{20}a \quad (1)$$

and

$$\sum F_x=m_{30}g-T_2=m_{30}a \quad (2)$$

Using a constant-acceleration equation, relate the speed at impact to the fall distance and the acceleration:

$$v^2=v_0^2+2a\Delta h$$

or, because $v_0=0$,

$$v^2=2a\Delta h\Rightarrow a=\frac{v^2}{2\Delta h}$$

Substitute numerical values and evaluate a:

$$a=\frac{(2.73\,\text{m/s})^2}{2(2.0\,\text{m})}=1.87\,\text{m/s}^2$$

Solve equation (1) for T_1 to obtain:

$$T_1=m_{20}(g+a)$$

Substitute numerical values and evaluate T_1:

$$T_1=(20\,\text{kg})(9.81\,\text{m/s}^2+1.87\,\text{m/s}^2)=\boxed{0.23\,\text{kN}}$$

Solve equation (2) for T_2 to obtain:

$$T_2=m_{30}(g-a)$$

Substitute numerical values and evaluate T_2:

$$T_2=(30\,\text{kg})(9.81\,\text{m/s}^2-1.87\,\text{m/s}^2)=\boxed{0.24\,\text{kN}}$$

(*d*) Noting that the initial speed of the 30-kg block is zero, express the time-of-fall in terms of the fall distance and the block's average speed:

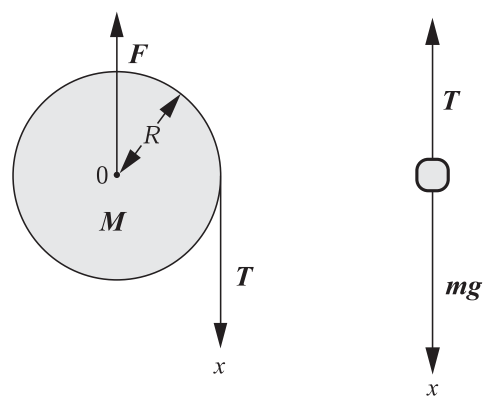
$$\Delta t = \frac{\Delta h}{v_{\text{av}}} = \frac{\Delta h}{\frac{1}{2}v} = \frac{2\Delta h}{v}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2(2.0\,\text{m})}{2.73\,\text{m/s}} = \boxed{1.5\,\text{s}}$$

77 •• A uniform solid sphere of mass *M* and radius *R* is free to rotate about a horizontal axis through its center. A string is wrapped around the sphere and is attached to an object of mass *m* (Figure 9-58). Assume that the string does not slip on the sphere. Find (*a*) the acceleration of the object, and (*b*) the tension in the string.

Picture the Problem The force diagram shows the forces acting on the sphere and the hanging object. The tension in the string is responsible for the angular acceleration of the sphere and the difference between the weight of the object and the tension is the net force acting on the hanging object. We can use Newton's second law to obtain two equations in *a* and *T* that we can solve simultaneously.



(*a*) Noting that $T = T'$, apply Newton's second law to the sphere and the hanging object:

$$\sum \tau_0 = TR = I_{\text{sphere}}\alpha \qquad (1)$$

and

$$\sum F_x = mg - T = ma \qquad (2)$$

Substitute for I_{sphere} and α in equation (1) to obtain:

$$TR = \left(\tfrac{2}{5}MR^2\right)\frac{a}{R} \qquad (3)$$

Eliminate *T* between equations (2) and (3) and solve for *a* to obtain:

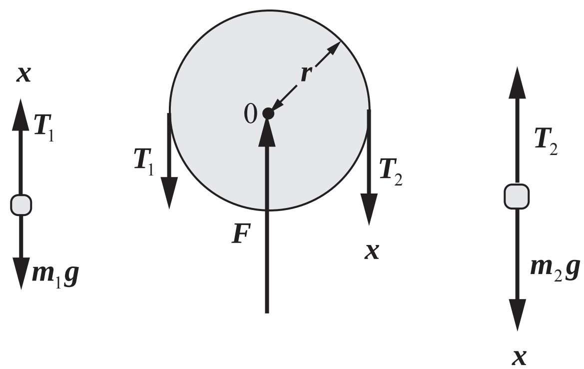
$$a = \boxed{\frac{g}{1 + \dfrac{2M}{5m}}}$$

(*b*) Substitute for a in equation (2) and solve for T to obtain:

$$T = \boxed{\frac{2mMg}{5m + 2M}}$$

78 •• Two objects, of masses m_1= 500 g and m_2 = 510 g, are connected by a string of negligible mass that passes over a pulley with frictionless bearings (Figure 9-59). The pulley is a uniform 50.0-g disk with a radius of 4.00 cm. The string does not slip on the pulley. (*a*) Find the accelerations of the objects. (*b*) What is the tension in the string between the 500-g block and the pulley? What is the tension in the string between the 510-g block and the pulley? By how much do these tensions differ? (*c*) What would your answers be if you neglected the mass of the pulley?

Picture the Problem The diagram shows the forces acting on both objects and the pulley. The direction of motion has been chosen to be the +*x* direction. By applying Newton's second law of motion, we can obtain a system of three equations in the unknowns T_1, T_2, and a that we can solve simultaneously.



(*a*) Apply Newton's second law to the pulley and the two objects:

$$\sum F_x = T_1 - m_1 g = m_1 a, \quad (1)$$

$$\sum \tau_0 = (T_2 - T_1)r = I_0 \alpha, \quad (2)$$

and

$$\sum F_x = m_2 g - T_2 = m_2 a \quad (3)$$

Substitute for $I_0 = I_{\text{pulley}}$ and α in equation (2) to obtain:

$$(T_2 - T_1)r = \left(\tfrac{1}{2}mr^2\right)\frac{a}{r} \quad (4)$$

Eliminate T_1 and T_2 between equations (1), (3) and (4) and solve for a to obtain:

$$a = \frac{(m_2 - m_1)g}{m_1 + m_2 + \frac{1}{2}m}$$

Substitute numerical values and evaluate a:

$$a = \frac{(510\text{ g} - 500\text{ g})(9.81\,\text{m/s}^2)}{500\text{ g} + 510\text{ g} + \frac{1}{2}(50.0\,\text{g})}$$

$$= 9.478\,\text{cm/s}^2 = \boxed{9.48\text{ cm/s}^2}$$

(*b*) Substitute for a in equation (1) and solve for T_1 to obtain:

$$T_1 = m_1(g+a) = (0.500\,\text{kg})(9.81\,\text{m/s}^2 + 0.09478\,\text{m/s}^2) = 4.952\ \text{N} = \boxed{4.95\ \text{N}}$$

Substitute for a in equation (3) and solve for T_2 to obtain:

$$T_2 = m_1(g-a) = (0.510\,\text{kg})(9.81\,\text{m/s}^2 - 0.09478\,\text{m/s}^2) = 4.955\ \text{N} = \boxed{4.96\ \text{N}}$$

ΔT is the difference between T_2 and T_1:

$$\Delta T = T_2 - T_1 = 4.96\ \text{N} - 4.95\,\text{N} = \boxed{0.01\,\text{N}}$$

(*c*) If we ignore the mass of the pulley, our acceleration equation becomes:

$$a = \frac{(m_2 - m_1)g}{m_1 + m_2}$$

Substitute numerical values and evaluate a:

$$a = \frac{(510\,\text{g} - 500\,\text{g})(9.81\,\text{m/s}^2)}{510\,\text{g} + 500\,\text{g}} = 9.713\,\text{cm/s}^2 = \boxed{9.71\,\text{cm/s}^2}$$

Substitute for a in equation (1) and solve for T_1 to obtain:

$$T_1 = m_1(g+a)$$

Substitute numerical values and evaluate T_1:

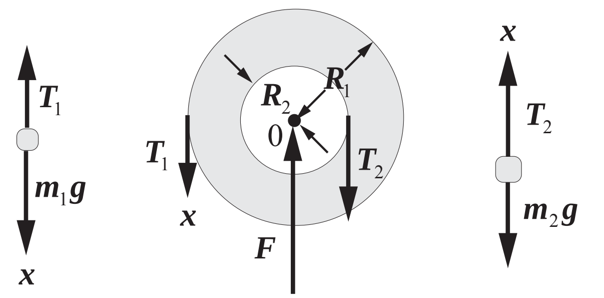
$$T_1 = (0.500\,\text{kg})(9.81\,\text{m/s}^2 + 0.09713\,\text{m/s}^2) = \boxed{4.95\,\text{N}}$$

From equation (4), if $m = 0$:

$$T_2 = T_1 = \boxed{4.95\,\text{N}}$$

79 •• [SSM] Two objects are attached to ropes that are attached to two wheels on a common axle, as shown in Figure 9-60. The two wheels are attached together so that they form a single rigid object. The moment of inertia of the rigid object is 40 kg·m^2. The radii of the wheels are R_1 = 1.2 m and R_2 = 0.40 m. (*a*) If m_1= 24 kg, find m_2 such that there is no angular acceleration of the wheels. (*b*) If 12 kg is placed on top of m_1, find the angular acceleration of the wheels and the tensions in the ropes.

Picture the Problem The following diagram shows the forces acting on both objects and the pulley for the conditions of Part (*a*). By applying Newton's second law of motion, we can obtain a system of three equations in the unknowns T_1, T_2, and α that we can solve simultaneously.



(*a*) When the system does not accelerate, $T_1 = m_1 g$ and $T_2 = m_2 g$. Under these conditions:

$$\sum \tau_0 = m_1 g R_1 - m_2 g R_2 = 0$$

Solving for m_2 yields:

$$m_2 = m_1 \frac{R_1}{R_2}$$

Substitute numerical values and evaluate m_2:

$$m_2 = (24\,\text{kg})\frac{1.2\,\text{m}}{0.40\,\text{m}} = \boxed{72\,\text{kg}}$$

(*b*) Apply Newton's second law to the objects and the pulley:

$$\sum F_x = m_1 g - T_1 = m_1 a, \qquad (1)$$

$$\sum \tau_0 = T_1 R_1 - T_2 R_2 = I_0 \alpha, \qquad (2)$$

and

$$\sum F_x = T_2 - m_2 g = m_2 a \qquad (3)$$

Eliminate a in favor of α in equations (1) and (3) and solve for T_1 and T_2:

$$T_1 = m_1 (g - R_1 \alpha) \qquad (4)$$

and

$$T_2 = m_2 (g + R_2 \alpha) \qquad (5)$$

Substitute for T_1 and T_2 in equation (2) and solve for α to obtain:

$$\alpha = \frac{(m_1 R_1 - m_2 R_2) g}{m_1 R_1^2 + m_2 R_2^2 + I_0}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{[(36\,\text{kg})(1.2\,\text{m}) - (72\,\text{kg})(0.40\,\text{m})](9.81\,\text{m/s}^2)}{(36\,\text{kg})(1.2\,\text{m})^2 + (72\,\text{kg})(0.40\,\text{m})^2 + 40\,\text{kg}\cdot\text{m}^2} = 1.37\,\text{rad/s}^2 = \boxed{1.4\,\text{rad/s}^2}$$

Substitute numerical values in equation (4) to find T_1:

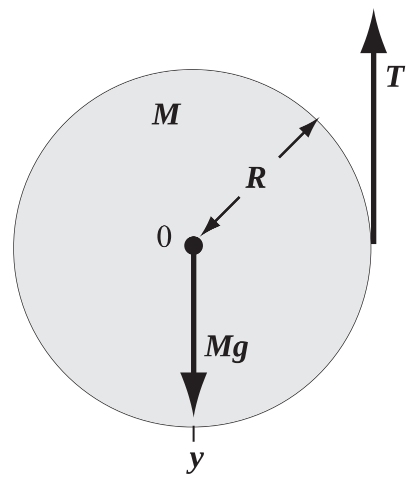
$$T_1 = (36\,\text{kg})[9.81\,\text{m/s}^2 - (1.2\,\text{m})(1.37\,\text{rad/s}^2)] = \boxed{0.29\,\text{kN}}$$

Substitute numerical values in equation (5) to find T_2:

$$T_2 = (72\,\text{kg})\left[9.81\,\text{m/s}^2 + (0.40\,\text{m})(1.37\,\text{rad/s}^2)\right] = \boxed{0.75\,\text{kN}}$$

80 •• The upper end of the string wrapped around the cylinder in Figure 9-61 is held by a hand that is accelerated upward so that the center of mass of the cylinder does not move as the cylinder spins up. Find (*a*) the tension in the string, (*b*) the angular acceleration of the cylinder, and (*c*) the acceleration of the hand.

Picture the Problem By applying Newton's second law of motion, we can obtain a system of two equations in the unknowns T and a. In (*b*) we can use the torque equation from (*a*) and our value for T to find α. In (*c*) we use the condition that the acceleration of a point on the rim of the cylinder is the same as the acceleration of the hand, together with the angular acceleration of the cylinder, to find the acceleration of the hand.



(*a*) Apply $\sum \tau_0 = I\alpha$ about an axis through its center of mass and $\sum F_y = 0$ to the cylinder to obtain:

$$\sum \tau_0 = TR = I_0\alpha \qquad (1)$$

and

$$\sum F_y = Mg - T = 0 \qquad (2)$$

Solving equation (2) for T yields:

$$T = \boxed{Mg}$$

(*b*) Solving equation (1) for α yields:

$$\alpha = \frac{TR}{I_0}$$

From Table 9-1, the moment of inertia of a cylinder about an axis through 0 and perpendicular to the end of the cylinder is:

$$I_0 = \tfrac{1}{2}MR^2$$

Substitute for T and I_0 and simplify to obtain:

$$\alpha = \frac{MgR}{\frac{1}{2}MR^2} = \boxed{\frac{2g}{R}}$$

(*c*) Relate the acceleration a of the hand to the angular acceleration of the cylinder:

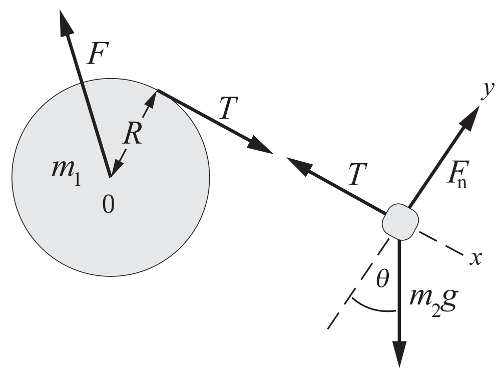
$$a = R\alpha$$

Substitute for α and simplify to obtain:

$$a = R\left(\frac{2g}{R}\right) = \boxed{2g}$$

81 •• [SSM] A uniform cylinder of mass m_1 and radius R is pivoted on frictionless bearings. A massless string wrapped around the cylinder is connected to a block of mass m_2 that is on a frictionless incline of angle θ, as shown in Figure 9-62. The system is released from rest with the block a vertical distance h above the bottom of the incline. (*a*) What is the acceleration of the block? (*b*) What is the tension in the string? (*c*) What is the speed of the block as it reaches the bottom of the incline? (*d*) Evaluate your answers for the special case where $\theta = 90°$ and $m_1 = 0$. Are your answers what you would expect for this special case? Explain.

Picture the Problem Let the zero of gravitational potential energy be at the bottom of the incline. By applying Newton's second law to the cylinder and the block we can obtain simultaneous equations in a, T, and α from which we can express a and T. By applying the conservation of energy, we can derive an expression for the speed of the block when it reaches the bottom of the incline.



(*a*) Apply Newton's second law to the cylinder and the block to obtain:

$$\sum \tau_0 = TR = I_0\alpha \qquad (1)$$

and

$$\sum F_x = m_2 g\sin\theta - T = m_2 a \qquad (2)$$

Substitute for α and I_0 in equation (1), solve for T, and substitute in equation (2) and solve for a to obtain:

$$a = \boxed{\frac{g\sin\theta}{1+\dfrac{m_1}{2m_2}}}$$

(*b*) Substituting for a in equation (2) and solve for T yields:

$$T = \boxed{\frac{\frac{1}{2}m_1 g\sin\theta}{1+\dfrac{m_1}{2m_2}}}$$

(*c*) Express the total energy of the system when the block is at the bottom of the incline in terms of its kinetic energies:

$$E_{\text{bottom}} = K_{\text{tran}} + K_{\text{rot}} = \tfrac{1}{2}m_2v^2 + \tfrac{1}{2}I_0\omega^2$$

Substitute for ω and I_0 to obtain:

$$\tfrac{1}{2}m_2v^2 + \tfrac{1}{2}\left(\tfrac{1}{2}m_1r^2\right)\frac{v^2}{r^2} = m_2gh$$

Solving for v yields:

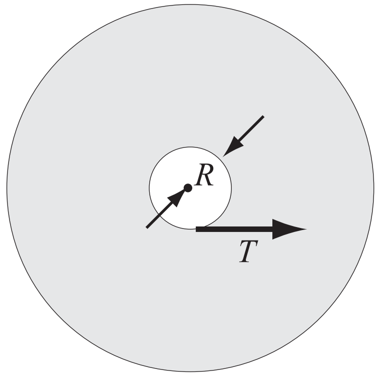
$$v = \boxed{\sqrt{\frac{2gh}{1+\dfrac{m_1}{2m_2}}}}$$

(*d*) For $\theta = 90°$ and $m_1 = 0$:

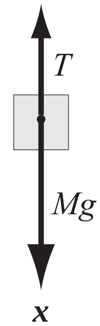
$$a = \boxed{g},\ T = \boxed{0},\ \text{and}\ v = \boxed{\sqrt{2gh}}$$

82 •• A device for measuring the moment of inertia of an object is shown in Figure 9-63. The circular platform is attached to a concentric drum of radius R, and the platform and the drum are free to rotate about a frictionless vertical axis. The string that is wound around the drum passes over a frictionless and massless pulley to a block of mass M. The block is released from rest, and the time t_1 it takes for it to drop a distance D is measured. The system is then rewound, the object whose moment of inertia I we wish to measure is placed on the platform, and the system is again released from rest. The time t_2 required for the block to drop the same distance D then provides the data needed to calculate I. Using $R = 10$ cm, $M = 2.5$ kg, $D = 1.8$ m and $t_1 = 4.2$ s and $t_2 = 6.8$ s, (*a*) find the moment of inertia of the platform-drum combination, (*b*) Find the moment of inertia of the platform-drum-object combination. (*c*) Use your results for Parts (*a*) and (*b*) to find the moment of inertia of the object.

Picture the Problem Let r be the radius of the concentric drum (10 cm) and let I_0 be the moment of inertia of the drum plus platform. We can use Newton's second law in both translational and rotational forms to express I_0 in terms of a and a constant-acceleration equation to express a and then find I_0. We can use the same equation to find the total moment of inertia when the object is placed on the platform and then subtract to find its moment of inertia.



Top view of platform



Side view of falling object

(*a*) Apply Newton's second law to the platform and the weight:

$$\sum \tau_0 = TR = I_0\alpha \qquad (1)$$

and

$$\sum F_x = Mg - T = Ma \qquad (2)$$

Substitute a/R for α in equation (1) and solve for T:

$$T = \frac{I_0}{R^2}a$$

Substitute for T in equation (2) and solve for I_0 to obtain:

$$I_0 = \frac{MR^2(g-a)}{a} \qquad (3)$$

Using a constant-acceleration equation, relate the distance of fall to the acceleration of the weight and the time of fall and solve for the acceleration:

$$\Delta x = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

or, because $v_0 = 0$ and $\Delta x = D$,

$$a = \frac{2D}{(\Delta t)^2}$$

Substitute for a in equation (3) to obtain:

$$I_0 = MR^2\left(\frac{g}{a} - 1\right) = MR^2\left(\frac{g(\Delta t)^2}{2D} - 1\right)$$

Substitute numerical values and evaluate I_0:

$$I_0 = (2.5\,\text{kg})(0.10\,\text{m})^2\left[\frac{(9.81\,\text{m/s}^2)(4.2\,\text{s})^2}{2(1.8\,\text{m})} - 1\right] = 1.177\,\text{kg}\cdot\text{m}^2 = \boxed{1.2\,\text{kg}\cdot\text{m}^2}$$

(*b*) Relate the moments of inertia of the platform, drum, shaft, and pulley (I_0) to the moment of inertia of the object and the total moment of inertia:

$$I_{\text{tot}} = I_0 + I = MR^2\left(\frac{g}{a} - 1\right)$$

$$= MR^2\left(\frac{g(\Delta t)^2}{2D} - 1\right)$$

Substitute numerical values and evaluate I_{tot}:

$$I_{tot} = (2.5\,\text{kg})(0.10\,\text{m})^2\left[\frac{(9.81\,\text{m/s}^2)(6.8\,\text{s})^2}{2(1.8\,\text{m})} - 1\right] = 3.125\,\text{kg}\cdot\text{m}^2 = \boxed{3.1\,\text{kg}\cdot\text{m}^2}$$

I is the difference between I_{tot} and I_0: $\quad I = I_{tot} - I_0$

Substitute numerical values and evaluate I:

$$I = 3.125\,\text{kg}\cdot\text{m}^2 - 1.177\,\text{kg}\cdot\text{m}^2 = \boxed{1.9\,\text{kg}\cdot\text{m}^2}$$

Objects Rotating and Rolling Without Slipping

83 • A homogeneous 60-kg cylinder of radius 18 cm is rolling without slipping along a horizontal floor at a speed of 15 m/s. What is the minimum amount of work that was required to give it this motion?

Picture the Problem Any work done on the cylinder by a net force will change its kinetic energy. Therefore, the work needed to give the cylinder this motion is equal to its kinetic energy.

Express the relationship between the work needed to give the cylinder this motion:

$$|W| = |\Delta K| = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2$$

or, because $v = r\omega$ (the cylinder is rolling without slipping),

$$|W| = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\left(\frac{v}{r}\right)^2$$

Substitute for I (see Table 9-1) and simplify to obtain:

$$|W| = \tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(\tfrac{1}{2}mr^2\right)\frac{v^2}{r^2} = \tfrac{3}{4}mv^2$$

Substitute numerical values and evaluate $|W|$:

$$|W| = \tfrac{3}{4}(60\,\text{kg})(15\,\text{m/s})^2 = \boxed{10\,\text{kJ}}$$

84 • An object is rolling without slipping. What percentage of its total kinetic energy is its translational kinetic energy if the object is (*a*) a uniform sphere, (*b*) a uniform cylinder, or (*c*) a hoop.

Picture the Problem The total kinetic energy of any object that is rolling without slipping is given by $K = K_{trans} + K_{rot}$. We can find the percentages associated with each motion by expressing the moment of inertia of the objects as kmr^2 and deriving a general expression for the ratios of rotational kinetic energy to total

kinetic energy and translational kinetic energy to total kinetic energy and substituting the appropriate values of k.

Express the total kinetic energy associated with a rotating and translating object:

$$K = K_{\text{trans}} + K_{\text{rot}} = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2$$
$$= \tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(kmr^2\right)\frac{v^2}{r^2}$$
$$= \tfrac{1}{2}mv^2 + \tfrac{1}{2}kmv^2 = \tfrac{1}{2}mv^2(1+k)$$

Express the ratio $\frac{K_{\text{trans}}}{K}$:

$$\frac{K_{\text{trans}}}{K} = \frac{\tfrac{1}{2}mv^2}{\tfrac{1}{2}mv^2(1+k)} = \frac{1}{1+k}$$

(a) Substitute $k = \frac{2}{5}$ for a uniform sphere to obtain:

$$\left.\frac{K_{\text{trans}}}{K}\right|_{\text{sphere}} = \frac{1}{1+0.4} = 0.714 = \boxed{71.4\%}$$

(b) Substitute $k = \frac{1}{2}$ for a uniform cylinder to obtain:

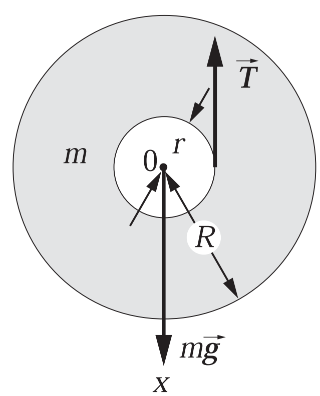
$$\left.\frac{K_{\text{trans}}}{K}\right|_{\text{cylinder}} = \frac{1}{1+0.5} = 0.667 = \boxed{66.7\%}$$

(c) Substitute $k = 1$ for a hoop to obtain:

$$\left.\frac{K_{\text{trans}}}{K}\right|_{\text{hoop}} = \frac{1}{1+1} = 0.500 = \boxed{50.0\%}$$

85 •• [SSM] In 1993 a giant 400-kg yo-yo with a radius of 1.5 m was dropped from a crane at a height of 57 m. One end of the string was tied to the top of the crane, so the yo-yo unwound as it descended. Assuming that the axle of the yo-yo had a radius of 0.10 m, estimate its linear speed at the end of the fall.

Picture the Problem The forces acting on the yo-yo are shown in the figure. We can use a constant-acceleration equation to relate the velocity of descent at the end of the fall to the yo-yo's acceleration and Newton's second law in both translational and rotational form to find the yo-yo's acceleration.



Using a constant-acceleration equation, relate the yo-yo's final speed to its acceleration and fall distance:

$$v^2 = v_0^2 + 2a\Delta h$$

or, because $v_0 = 0$,

$$v = \sqrt{2a\Delta h} \qquad (1)$$

Use Newton's second law to relate the forces that act on the yo-yo to its acceleration:

$$\sum F_x = mg - T = ma \qquad (2)$$

and

$$\sum \tau_0 = Tr = I_0\alpha \qquad (3)$$

Use $a = r\alpha$ to eliminate α in equation (3)

$$Tr = I_0 \frac{a}{r} \qquad (4)$$

Eliminate T between equations (2) and (4) to obtain:

$$mg - \frac{I_0}{r^2} a = ma \qquad (5)$$

Substitute $\frac{1}{2}mR^2$ for I_0 in equation (5):

$$mg - \frac{\frac{1}{2}mR^2}{r^2} a = ma \Rightarrow a = \frac{g}{1 + \dfrac{R^2}{2r^2}}$$

Substitute numerical values and evaluate a:

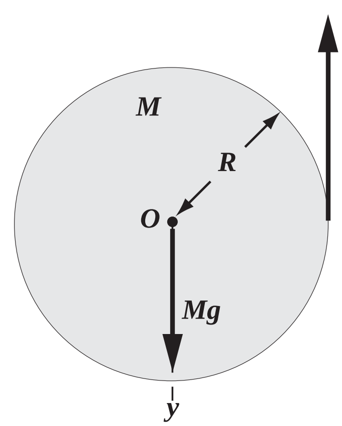
$$a = \frac{9.81\,\text{m/s}^2}{1 + \dfrac{(1.5\,\text{m})^2}{2(0.10\,\text{m})^2}} = 0.0864\,\text{m/s}^2$$

Substitute in equation (1) and evaluate v:

$$v = \sqrt{2(0.0864\,\text{m/s}^2)(57\,\text{m})} = \boxed{3.1\,\text{m/s}}$$

86 •• A uniform cylinder of mass M and radius R has a string wrapped around it. The string is held fixed, and the cylinder falls vertically as shown in Figure 9-61. (*a*) Show that the acceleration of the cylinder is downward with a magnitude $a = 2g/3$. (*b*) Find the tension in the string.

Picture the Problem The forces acting on the cylinder are shown in the diagram. Choose a coordinate system in which the +y directions is downward. By applying Newton's second law of motion, we can obtain a system of two equations in the unknowns T, a and α that we can solve simultaneously.



(*a*) Apply Newton's second law to the cylinder:

$$\sum \tau_0 = TR = I_0\alpha \qquad (1)$$

and

$$\sum F_y = Mg - T = Ma \qquad (2)$$

Substitute for α and I_0 (see Table 9-1) in equation (1) to obtain:

$$TR = \left(\tfrac{1}{2}MR^2\right)\left(\frac{a}{R}\right) \Rightarrow T = \tfrac{1}{2}Ma \quad (3)$$

Substitute for T in equation (2) to obtain:

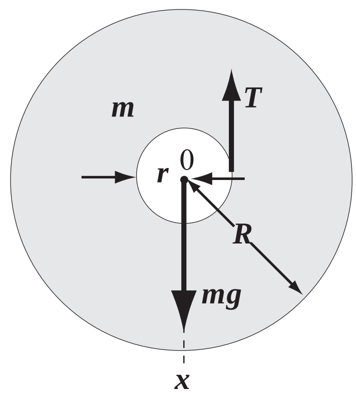
$$Mg - \tfrac{1}{2}Ma = Ma \Rightarrow a = \boxed{\tfrac{2}{3}g}$$

(*b*) Substitute for a in equation (3) and simplify to obtain:

$$T = \tfrac{1}{2}M\left(\tfrac{2}{3}g\right) = \boxed{\tfrac{1}{3}Mg}$$

87 •• A 0.10-kg yo-yo consists of two solid disks, each of radius 10 cm, is joined by a massless rod of radius 1.0 cm. A string is wrapped around the rod. One end of the string is held fixed and is under tension as the yo-yo is released. The yo-yo rotates as it descends vertically. Find (*a*) the acceleration of the yo-yo, and (*b*) the tension *T*.

Picture the Problem The forces acting on the yo-yo are shown in the figure. Choose a coordinate system in which the $+x$ direction is downward. Apply Newton's second law in both translational and rotational form to obtain simultaneous equations in T, a, and α from which we can eliminate α and solve for T and a.



Apply Newton's second law to the yo-yo:

$$\sum F_x = mg - T = ma \quad (1)$$

and

$$\sum \tau_0 = Tr = I_0\alpha \quad (2)$$

Use $a = r\alpha$ to eliminate α in equation (2)

$$Tr = I_0\frac{a}{r} \quad (3)$$

Eliminate T between equations (1) and (3) to obtain:

$$mg - \frac{I_0}{r^2}a = ma \quad (4)$$

Substitute $\tfrac{1}{2}mR^2$ for I_0 (see Table 9-1) in equation (4):

$$mg - \frac{\tfrac{1}{2}mR^2}{r^2}a = ma \Rightarrow a = \frac{g}{1 + \dfrac{R^2}{2r^2}}$$

Substitute numerical values and evaluate a:

$$a=\frac{9.81\,\text{m/s}^2}{1+\dfrac{(0.10\,\text{m})^2}{2(0.010\,\text{m})^2}}=0.192\,\text{m/s}^2$$
$$=\boxed{0.19\,\text{m/s}^2}$$

Solving equation (1) for T yields:

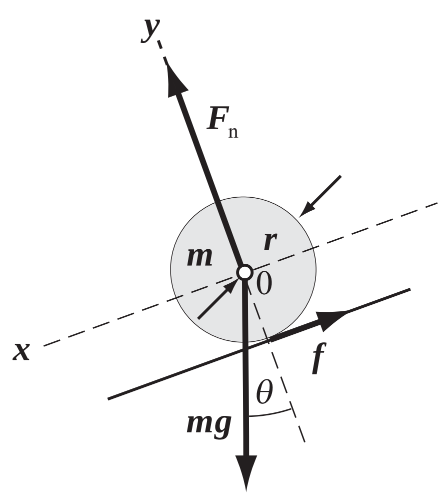
$$T=m(g-a)$$

Substitute numerical values and evaluate T:

$$T=(0.10\,\text{kg})\left(9.81\,\text{m/s}^2-0.192\,\text{m/s}^2\right)$$
$$=\boxed{0.96\,\text{N}}$$

88 •• A uniform solid sphere rolls down an incline without slipping. If the linear acceleration of the center of mass of the sphere is $0.2g$, then what is the angle the incline makes with the horizontal?

Picture the Problem From Newton's second law, the acceleration of the center of mass of the uniform solid sphere equals the net force acting on the sphere divided by its mass. The forces acting on the sphere are its weight $m\vec{g}$ downward, the normal force $\vec{F}_n$ that balances the normal component of the weight, and the force of friction $\vec{f}$ acting up the incline. As the sphere accelerates down the incline, the angular speed of rotation must increase to maintain the nonslip condition. We can apply Newton's second law for rotation about a horizontal axis through the center of mass of the sphere to find α, which is related to the acceleration by the nonslip condition. The only torque about the center of mass is due to $\vec{f}$ because both $m\vec{g}$ and $\vec{F}_n$ act through the center of mass. Choose the $+x$ direction to be down the incline.



Apply $\sum\vec{F}=m\vec{a}$ to the sphere: $$mg\sin\theta-f=ma_{cm} \quad (1)$$

Apply $\sum\tau=I_{cm}\alpha$ to the sphere: $$fr=I_{cm}\alpha$$

Use the nonslip condition to eliminate α and solve for f:

$$fr = I_{\text{cm}}\frac{a_{\text{cm}}}{r} \Rightarrow f = \frac{I_{\text{cm}}}{r^2}a_{\text{cm}}$$

Substitute this result for f in equation (1) to obtain:

$$mg\sin\theta - \frac{I_{\text{cm}}}{r^2}a_{\text{cm}} = ma_{\text{cm}} \qquad (2)$$

From Table 9-1 we have, for a solid sphere:

$$I_{\text{cm}} = \tfrac{2}{5}mr^2$$

Substitute for I_{cm} in equation (1) and simplify to obtain:

$$mg\sin\theta - \tfrac{2}{5}ma_{\text{cm}} = ma_{\text{cm}}$$

Solving for θ yields:

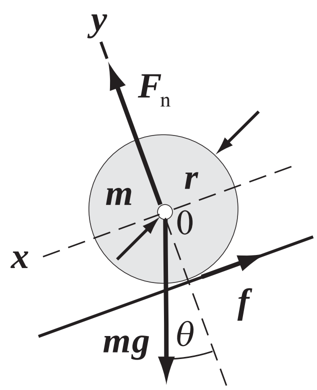
$$\theta = \sin^{-1}\left(\frac{7a_{\text{cm}}}{5g}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{7(0.2g)}{5g}\right] = \boxed{16°}$$

89 •• A thin spherical shell rolls down an incline without slipping. If the linear acceleration of the center of mass of the shell is 0.20*g,* then what is the angle the incline makes with the horizontal?

Picture the Problem From Newton's second law, the acceleration of the center of mass of the thin spherical shell equals the net force acting on the spherical shell divided by its mass. The forces acting on the thin spherical shell are its weight $m\vec{g}$ downward, the normal force $\vec{F}_{\text{n}}$ that balances the normal component of the weight, and the force of friction $\vec{f}$ acting up the incline. As the spherical shell accelerates down the incline, the angular speed of rotation must increase to maintain the nonslip condition. We can apply Newton's second law for rotation about a horizontal axis through the center of mass of the shell to find α, which is related to the acceleration by the nonslip condition. The only torque about the center of mass is due to $\vec{f}$ because both $m\vec{g}$ and $\vec{F}_{\text{n}}$ act through the center of mass. Choose the $+x$ direction to be down the incline.



Apply $\sum \vec{F} = m\vec{a}$ to the thin spherical shell:

$$mg\sin\theta - f = ma_{\text{cm}} \qquad (1)$$

Apply $\sum \tau = I_{\text{cm}}\alpha$ to the thin spherical shell:

$$fr = I_{\text{cm}}\alpha$$

Use the nonslip condition to eliminate α and solve for f:

$$fr = I_{\text{cm}}\frac{a_{\text{cm}}}{r} \text{ and } f = \frac{I_{\text{cm}}}{r^2}a_{\text{cm}}$$

Substitute this result for f in equation (1) to obtain:

$$mg\sin\theta - \frac{I_{\text{cm}}}{r^2}a_{\text{cm}} = ma_{\text{cm}} \qquad (2)$$

From Table 9-1 we have, for a thin spherical shell:

$$I_{\text{cm}} = \tfrac{2}{3}mr^2$$

Substitute for I_{cm} in equation (1) and simplify to obtain:

$$mg\sin\theta - \tfrac{2}{3}ma_{\text{cm}} = ma_{\text{cm}}$$

Solving for θ yields:

$$\theta = \sin^{-1}\left(\frac{5a_{\text{cm}}}{3g}\right)$$

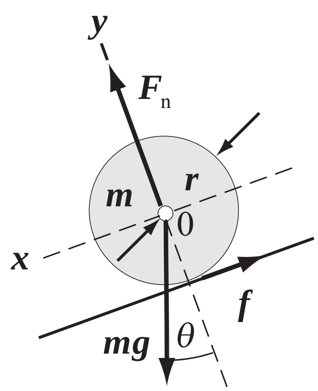
Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{5(0.20g)}{3g}\right] = \boxed{20°}$$

Remarks: This larger angle makes sense, as the moment of inertia for a given mass is larger for a thin spherical shell than for a solid one.

90 •• A basketball rolls without slipping down an incline of angle θ. The coefficient of static friction is μ_s. Model the ball as a thin spherical shell. Find (*a*) the acceleration of the center of mass of the ball, (*b*) the frictional force acting on the ball, and (*c*) the maximum angle of the incline for which the ball will roll without slipping.

Picture the Problem The three forces acting on the basketball are the weight of the ball, the normal force, and the force of friction. Because the weight can be assumed to be acting at the center of mass, and the normal force acts through the center of mass, the only force which exerts a torque about the center of mass is the frictional force. Let the mass of the basketball be m and apply Newton's second law to find a system of simultaneous equations that we can solve for the quantities called for in the problem statement.



(a) Apply Newton's second law in both translational and rotational form to the ball:

$$\sum F_x = mg\sin\theta - f_s = ma\,, \qquad (1)$$

$$\sum F_y = F_n - mg\cos\theta = 0 \qquad (2)$$

and

$$\sum \tau_0 = f_s r = I_0\alpha \qquad (3)$$

Because the basketball is rolling without slipping we know that:

$$\alpha = \frac{a}{r}$$

Substitute in equation (3) to obtain:

$$f_s r = I_0\frac{a}{r} \qquad (4)$$

From Table 9-1 we have:

$$I_0 = \tfrac{2}{3}mr^2$$

Substitute for I_0 and α in equation (4) and solve for f_s:

$$f_s r = \left(\tfrac{2}{3}mr^2\right)\frac{a}{r} \Rightarrow f_s = \tfrac{2}{3}ma \qquad (5)$$

Substitute for f_s in equation (1) and solve for a:

$$a = \boxed{\tfrac{3}{5}g\sin\theta}$$

(b) Find f_s using equation (5):

$$f_s = \tfrac{2}{3}m\left(\tfrac{3}{5}g\sin\theta\right) = \boxed{\tfrac{2}{5}mg\sin\theta}$$

(c) Solve equation (2) for F_n:

$$F_n = mg\cos\theta$$

Use the definition of $f_{s,max}$ to obtain:

$$f_{s,max} = \mu_s F_n = \mu_s mg\cos\theta_{max}$$

Use the result of Part (b) to obtain:

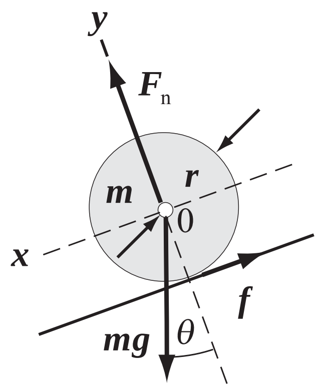
$$\tfrac{2}{5}mg\sin\theta_{max} = \mu_s mg\cos\theta_{max}$$

Solve for θ_{max}:

$$\theta_{max} = \boxed{\tan^{-1}\left(\tfrac{5}{2}\mu_s\right)}$$

91 •• A uniform solid cylinder of wood rolls without slipping down an incline of angle θ. The coefficient of static friction is μ_s. Find (*a*) the acceleration of the center of mass of the cylinder, (*b*) the frictional force acting on the cylinder, and (*c*) the maximum angle of the incline for which the cylinder will roll without slipping.

Picture the Problem The three forces acting on the cylinder are the weight of the cylinder, the normal force, and the force of friction. Because the weight can be assumed to be acting at the center of mass, and the normal force acts through the center of mass, the only force which exerts a torque about the center of mass is the frictional force. Let the mass of the cylinder by m and use Newton's second law to find a system of simultaneous equations that we can solve for the quantities called for in the problem statement.



(*a*) Apply Newton's second law in both translational and rotational form to the cylinder:

$$\sum F_x = mg\sin\theta - f_s = ma\,, \quad (1)$$

$$\sum F_y = F_n - mg\cos\theta = 0 \quad (2)$$

and

$$\sum \tau_0 = f_s r = I_0\alpha \quad (3)$$

Because the cylinder is rolling without slipping we know that:

$$\alpha = \frac{a}{r}$$

Substitute in equation (3) to obtain:

$$f_s r = I_0\frac{a}{r} \quad (4)$$

From Table 9-1 we have:

$$I_0 = \tfrac{1}{2}mr^2$$

Substitute for I_0 and α in equation (4) and solve for f_s:

$$f_s r = \left(\tfrac{1}{2}mr^2\right)\frac{a}{r} \Rightarrow f_s = \tfrac{1}{2}ma \quad (5)$$

Substitute for f_s in equation (1) and solve for a:

$$a = \boxed{\tfrac{2}{3}g\sin\theta}$$

(*b*) Find f_s using equation (5): $f_s = \frac{1}{2}m\left(\frac{2}{3}g\sin\theta\right) = \boxed{\frac{1}{3}mg\sin\theta}$

(*c*) Solve equation (2) for F_n: $F_n = mg\cos\theta$

Use the definition of $f_{s,max}$ to obtain: $f_{s,max} = \mu_s F_n = \mu_s mg\cos\theta_{max}$

Use the result of part (*b*) to obtain: $\frac{1}{3}mg\sin\theta_{max} = \mu_s mg\cos\theta_{max}$

Solving for θ_{max} gives: $\theta_{max} = \boxed{\tan^{-1}(3\mu_s)}$

92 •• Released from rest at the same height, a thin spherical shell and solid sphere of the same mass m and radius R roll without slipping down an incline through the same vertical drop H (Figure 9-64). Each is moving horizontally as it leaves the ramp. The spherical shell hits the ground a horizontal distance L from the end of the ramp and the solid sphere hits the ground a distance L' from the end of the ramp. Find the ratio L'/L.

Picture the Problem Let the zero of gravitational potential energy be at the elevation where the spheres leave the ramp. The distances the spheres will travel are directly proportional to their speeds when they leave the ramp.

Express the ratio of the distances traveled by the two spheres in terms of their speeds when they leave the ramp:

$$\frac{L'}{L} = \frac{v_{solid}\Delta t}{v_{shell}\Delta t} = \frac{v_{solid}}{v_{shell}} \qquad (1)$$

Use conservation of mechanical energy to find the speed of the spheres when they leave the ramp:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$K_f - U_i = 0 \qquad (2)$$

Express K_f for the spheres and simplify to obtain (Note that $k = 2/3$ for the spherical shell and 2/5 for the uniform sphere):

$$\begin{aligned} K_f &= K_{trans} + K_{rot} = \frac{1}{2}mv^2 + \frac{1}{2}I_{cm}\omega^2 \\ &= \frac{1}{2}mv^2 + \frac{1}{2}\left(kmR^2\right)\frac{v^2}{R^2} \\ &= \frac{1}{2}mv^2 + \frac{1}{2}kmv^2 = (1+k)\frac{1}{2}mv^2 \end{aligned}$$

Substitute for K_f in equation (2) to obtain:

$$(1+k)\frac{1}{2}mv^2 = mgH \Rightarrow v = \sqrt{\frac{2gH}{1+k}}$$

Substitute for v_{shell} and v_{solid} in equation (1) and simplify to obtain:

$$\frac{L'}{L} = \sqrt{\frac{1+k_{shell}}{1+k_{solid}}} = \sqrt{\frac{1+\frac{2}{3}}{1+\frac{2}{5}}} = \boxed{1.09}$$

93 •• [SSM] A uniform, thin cylindrical shell and a solid cylinder roll horizontally without slipping. The speed of the cylindrical shell is v. The solid cylinder and the hollow cylinder encounter an incline that they climb without slipping. If the maximum height they reach is the same, find the initial speed v' of the solid cylinder.

Picture the Problem Let the subscripts s and c refer to the thin cylindrical shell and solid cylinder, respectively. Because the cylinders climb to the same height, their kinetic energies at the bottom of the incline must be equal.

Express the total kinetic energy of the thin cylindrical shell at the bottom of the inclined plane:

$$K_s = K_{trans} + K_{rot} = \tfrac{1}{2}m_s v^2 + \tfrac{1}{2}I_s\omega^2 = \tfrac{1}{2}m_s v^2 + \tfrac{1}{2}\left(m_s r^2\right)\frac{v^2}{r^2} = m_s v^2$$

Express the total kinetic energy of the solid cylinder at the bottom of the inclined plane:

$$K_c = K_{trans} + K_{rot} = \tfrac{1}{2}m_c v'^2 + \tfrac{1}{2}I_c\omega'^2 = \tfrac{1}{2}m_c v'^2 + \tfrac{1}{2}\left(\tfrac{1}{2}m_c r^2\right)\frac{v'^2}{r^2} = \tfrac{3}{4}m_c v'^2$$

Because the cylinders climb to the same height:

$$\tfrac{3}{4}m_s v'^2 = m_s gh \Rightarrow \tfrac{3}{4}v'^2 = gh$$

and

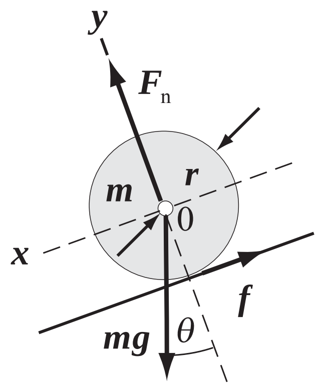
$$m_c v^2 = m_c gh \Rightarrow v^2 = gh$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{\tfrac{3}{4}v'^2}{v^2} = \frac{gh}{gh} \Rightarrow v' = \boxed{\sqrt{\frac{4}{3}}v}$$

94 •• A thin cylindrical shell and a solid sphere start from rest and roll without slipping down a 3.0-m-long inclined plane. The cylinder arrives at the bottom of the incline 2.4 s after the sphere does. Determine the angle the incline makes with the horizontal.

Picture the Problem Let the subscripts s and c refer to the solid sphere and thin-walled cylinder, respectively. Because the cylinder and sphere descend from the same height, their kinetic energies at the bottom of the incline must be equal. The force diagram shows the forces acting on the solid sphere. We'll use Newton's second law to relate the accelerations to the angle of the incline and use a constant acceleration to relate the accelerations to the distances traveled down the incline.



Apply Newton's second law to the sphere:	$\sum F_x = mg\sin\theta - f_s = ma_s$, (1) $\sum F_y = F_n - mg\cos\theta = 0$, (2) and $\sum \tau_0 = f_s r = I_0\alpha$ (3)
Substitute for I_0 and α in equation (3) and solve for f_s:	$f_s r = \left(\frac{2}{5}mr^2\right)\frac{a}{r} \Rightarrow f_s = \frac{2}{5}ma_s$
Substitute for f_s in equation (1) and solve for a_s:	$a_s = \frac{5}{7}g\sin\theta$
Proceed as above for the thin cylindrical shell to obtain:	$a_c = \frac{1}{2}g\sin\theta$
Using a constant-acceleration equation, relate the distance traveled down the incline to the acceleration and elapsed time:	$\Delta s = v_0 t + \frac{1}{2}at^2$ or, because $v_0 = 0$, $\Delta s = \frac{1}{2}at^2 \Rightarrow t = \sqrt{\frac{2\Delta s}{a}}$ (4)
Substituting for a_s and a_c in equation (4) gives:	$t_s = \sqrt{\frac{2\Delta s}{\frac{5}{7}g\sin\theta}}$ and $t_c = \sqrt{\frac{2\Delta s}{\frac{1}{2}g\sin\theta}}$
Because $t_c - t_s = 2.4\text{ s}$:	$\sqrt{\frac{2\Delta s}{\frac{1}{2}g\sin\theta}} - \sqrt{\frac{2\Delta s}{\frac{5}{7}g\sin\theta}} = 2.4\text{ s}$

Solving for θ gives:

$$\theta = \sin^{-1}\left[\frac{\sqrt{\frac{4\Delta s}{g}} - \sqrt{\frac{14\Delta s}{5g}}}{2.4\,\text{s}}\right]^2$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{\sqrt{\frac{4(3.0\,\text{m})}{9.81\,\text{m/s}^2}} - \sqrt{\frac{14(3.0\,\text{m})}{5(9.81\,\text{m/s}^2)}}}{2.4\,\text{s}}\right]^2 = \boxed{0.058°}$$

95 •• A wheel has a thin 3.0-kg rim and four spokes, each of mass 1.2 kg. Find the kinetic energy of the wheel when it is rolling at 6.0 m/s on a horizontal surface.

Picture the Problem The kinetic energy of the wheel is the sum of its translational and rotational kinetic energies. Because the wheel is a composite object, we can model its moment of inertia by treating the rim as a cylindrical shell and the spokes as rods.

Express the kinetic energy of the wheel:

$$K = K_{\text{trans}} + K_{\text{rot}} = \tfrac{1}{2}M_{\text{tot}}v^2 + \tfrac{1}{2}I_{\text{cm}}\omega^2 = \tfrac{1}{2}M_{\text{tot}}v^2 + \tfrac{1}{2}I_{\text{cm}}\frac{v^2}{R^2}$$

where $M_{\text{tot}} = M_{\text{rim}} + 4M_{\text{spoke}}$.

The moment of inertia of the wheel is the sum of the moments of inertia of the rim and spokes:

$$I_{\text{cm}} = I_{\text{rim}} + I_{\text{spokes}} = M_{\text{rim}}R^2 + 4\left(\tfrac{1}{3}M_{\text{spoke}}R^2\right) = \left(M_{\text{rim}} + \tfrac{4}{3}M_{\text{spoke}}\right)R^2$$

Substitute for I_{cm} in the equation for K:

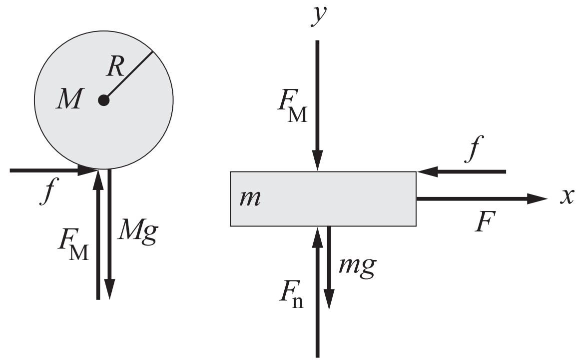
$$K = \tfrac{1}{2}M_{\text{tot}}v^2 + \tfrac{1}{2}\left[\left(M_{\text{rim}} + \tfrac{4}{3}M_{\text{spoke}}\right)R^2\right]\frac{v^2}{R^2} = \left[\tfrac{1}{2}\left(M_{\text{tot}} + M_{\text{rim}}\right) + \tfrac{2}{3}M_{\text{spoke}}\right]v^2$$

Substitute numerical values and evaluate K:

$$K = \left[\tfrac{1}{2}(7.8\,\text{kg} + 3.0\,\text{kg}) + \tfrac{2}{3}(1.2\,\text{kg})\right](6.0\,\text{m/s})^2 = \boxed{0.22\,\text{kJ}}$$

96 ••• A uniform solid cylinder of mass M and radius R is at rest on a slab of mass m, which in turn rests on a horizontal, frictionless table (Figure 9-65). If a horizontal force $\vec{F}$ is applied to the slab, it accelerates and the cylinder rolls without slipping. Find the acceleration of the slab in terms of M, R, and F.

Picture the Problem Let the letter S identify the slab and the letter C the cylinder. We can find the accelerations of the slab and cylinder by applying Newton's second law and solving the resulting equations simultaneously.



Apply $\sum F_x = ma_x$ to the slab: $F - f = ma_S$ (1)

Apply $\sum F_x = ma_x$ to the cylinder: $f = Ma_C$, (2)

Apply $\sum \tau_{CM} = I_{CM}\alpha$ to the cylinder: $fR = I_{CM}\alpha$ (3)

Substitute for I_{CM} in equation (3) and solve for f to obtain: $f = \frac{1}{2}MR\alpha$ (4)

Relate the acceleration of the slab to the acceleration of the cylinder:

$a_C = a_S + a_{CS}$

or, because $a_{CS} = -R\alpha$ is the acceleration of the cylinder relative to the slab,

$a_C = a_S - R\alpha \Rightarrow R\alpha = a_S - a_C$ (5)

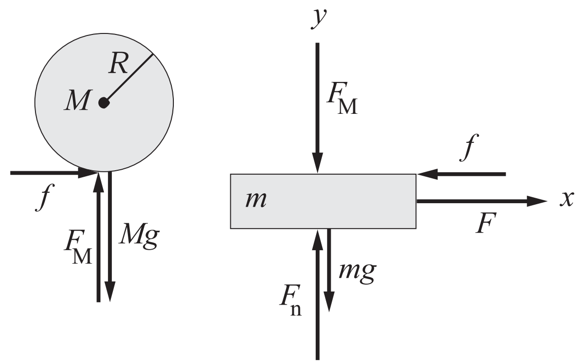
Equate equations (2) and (4) and substitute from (5) to obtain: $a_S = 3a_C$

Substitute equation (4) in equation (1) and substitute for a_C to obtain:

$$F - \tfrac{1}{3}Ma_S = ma_S \Rightarrow a_S = \boxed{\frac{3F}{M + 3m}}$$

97 ••• (*a*) Find the angular acceleration of the cylinder in Problem 96. Is the cylinder rotating clockwise or counterclockwise? (*b*) What is the cylinder's linear acceleration (magnitude and direction) relative to the table? (*c*) What is the magnitude and direction of the linear acceleration of the center of mass of the cylinder relative to the slab?

Picture the Problem Let the letter S identify the slab and the letter C the cylinder. In this problem, as in Problem 96, we can find the accelerations of the slab and cylinder by applying Newton's second law and solving the resulting equations simultaneously.



(*a*) Because the cylinder rolls without slipping, its angular acceleration is the quotient of its linear acceleration and its radius:

$$\alpha = \frac{a_c}{R} \qquad (1)$$

Apply $\sum F_x = ma_x$ to the slab:

$$F - f = ma_S \qquad (2)$$

Apply $\sum F_x = ma_x$ to the cylinder:

$$f = Ma_C\,, \qquad (3)$$

Apply $\sum \tau_{CM} = I_{CM}\alpha$ to the cylinder:

$$fR = I_{CM}\alpha \qquad (4)$$

Substitute for I_{CM} in equation (4) and solve for f to obtain:

$$f = \tfrac{1}{2}MR\alpha \qquad (5)$$

Relate the acceleration of the slab to the acceleration of the cylinder:

$$a_C = a_S + a_{CS}$$

or, because $a_{CS} = -R\alpha$,

$$a_C = a_S - R\alpha \Rightarrow \alpha = \frac{a_S - a_C}{R} \qquad (6)$$

Equate equations (3) and (5) and substitute from (6) to obtain:

$$a_S = 3a_C$$

Substituting for f and a_s in equation (1) gives:

$$F - Ma_c = 3ma_c \Rightarrow a_c = \frac{F}{3m+M}$$

Substitute for a_c in equation (1) and simplify to obtain:

$$\alpha = \boxed{\frac{F}{R(3m+M)}, \text{ counterclockwise}}$$

(*b*) From equations (2) and (5) we have:

$$F - \tfrac{1}{3}Ma_S = ma_S \Rightarrow a_S = \frac{3F}{M+3m}$$

Because $a_S = 3a_C$:

$$a_C = \tfrac{1}{3}a_S = \boxed{\frac{F}{M+3m}}$$

in the direction of $\vec{F}$.

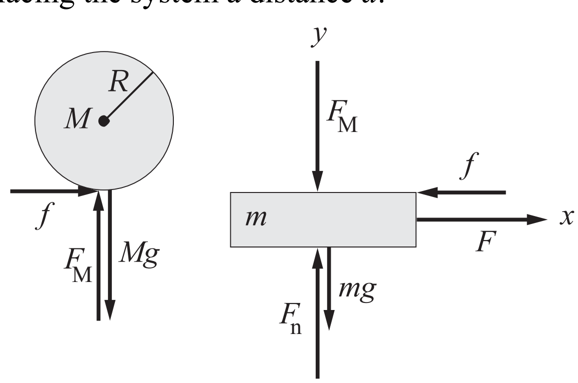
(*c*) The acceleration of the cylinder relative to the slab is the difference between the acceleration of the cylinder and the acceleration of the slab:

$$a_{CS} = a_C - a_S = a_C - 3a_C = -2a_C$$
$$= \boxed{-\frac{2F}{M+3m}}$$

opposite the direction of $\vec{F}$.

98 ••• If the force in Problem 96 acts over a distance *d*, in terms of the symbols given, find (*a*) the kinetic energy of the slab, and (*b*) the total kinetic energy of the cylinder. (*c*) Show that the total kinetic energy of the slab-cylinder system is equal to the work done by the force.

Picture the Problem Let the system include Earth, the cylinder (C), and the slab (S). Then $\vec{F}$ is an external force that changes the energy of the system by doing work on it. We can find the kinetic energy of the slab from its speed when it has traveled a distance *d*. We can find the kinetic energy of the cylinder from the sum of its translational and rotational kinetic energies. In Part (*c*) we can add the kinetic energies of the slab and the cylinder to show that their sum is the work done by $\vec{F}$ in displacing the system a distance *d*.



(*a*) Express the kinetic energy of the slab: $K_S = W_{\text{on slab}} = \frac{1}{2}mv_S^2$

Using a constant-acceleration equation, relate the velocity of the slab to its acceleration and the distance traveled: $v_S^2 = v_0^2 + 2a_S d$

or, because the slab starts from rest,

$v_S^2 = 2a_S d$

Substitute for v_S^2 to obtain: $K_S = \frac{1}{2}m(2a_S d) = ma_S d \quad (1)$

Apply $\sum F_x = ma_x$ to the slab: $F - f = ma_S \quad (2)$

Apply $\sum F_x = ma_x$ to the cylinder: $f = Ma_C\,, \quad (3)$

Apply $\sum \tau_{CM} = I_{CM}\alpha$ to the cylinder: $fR = I_{CM}\alpha \quad (4)$

Substitute for I_{CM} in equation (4) and solve for f: $f = \frac{1}{2}MR\alpha \quad (5)$

Relate the acceleration of the slab to the acceleration of the cylinder: $a_C = a_S + a_{CS}$

or, because $a_{CS} = -R\alpha$,

$a_C = a_S - R\alpha$

Solving for $R\alpha$ yields: $R\alpha = a_S - a_C \quad (6)$

Equate equations (3) and (5) and substitute in (6) to obtain: $a_S = 3a_C$

Substitute equation (5) in equation (2) and use $a_S = 3a_C$ to obtain: $F - Ma_C = ma_S$

or

$F - \frac{1}{3}Ma_S = ma_S$

Solving for a_S yields:

$$a_S = \frac{F}{m + \frac{1}{3}M}$$

Substitute for a_S in equation (1) to obtain:

$$K_S = \boxed{\frac{mFd}{m + \frac{1}{3}M}}$$

(*b*) Express the total kinetic energy of the cylinder:

$$K_C = K_{trans} + K_{rot} = \tfrac{1}{2}Mv_C^2 + \tfrac{1}{2}I_{CM}\omega^2 = \tfrac{1}{2}Mv_C^2 + \tfrac{1}{2}I_{CM}\frac{v_{CB}^2}{R^2} \qquad (7)$$

where $v_{CS} = v_C - v_S$.

In Part (*a*) it was established that:

$$a_S = 3a_C$$

Integrate both sides of $a_S = 3a_C$ with respect to time to obtain:

$$v_S = 3v_C + \text{constant}$$

where the constant of integration is determined by the initial conditions that $v_C = 0$ when $v_S = 0$.

Substitute the initial conditions to obtain:

$$\text{constant} = 0 \text{ and } v_S = 3v_C$$

Substitute in the expression for v_{CS} to obtain:

$$v_{CS} = v_C - v_S = v_C - 3v_C = -2v_C$$

Substitute for I_{CM} and v_{CS} in equation (7) to obtain:

$$K_C = \tfrac{1}{2}Mv_C^2 + \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\frac{(-2v_C)^2}{R^2} = \tfrac{3}{2}Mv_C^2 \qquad (8)$$

Because $v_C = \tfrac{1}{3}v_S$:

$$v_C^2 = \tfrac{1}{9}v_S^2$$

It Part (*a*) it was established that:

$$v_S^2 = 2a_S d \text{ and } a_S = \frac{F}{m + \tfrac{1}{3}M}$$

Substitute to obtain:

$$v_C^2 = \tfrac{1}{9}(2a_S d) = \tfrac{2}{9}\left(\frac{F}{m + \tfrac{1}{3}M}\right)d = \frac{2Fd}{9\left(m + \tfrac{1}{3}M\right)}$$

Substituting in equation (8) and simplifying yields:

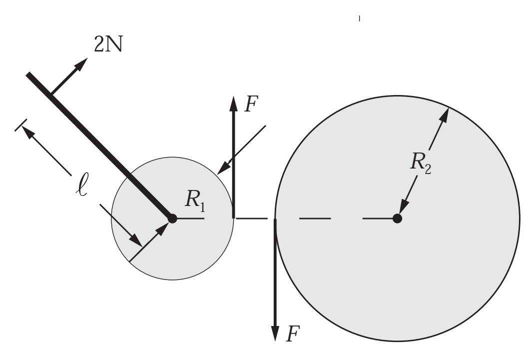
$$K_C = \tfrac{3}{2}M\left(\frac{2Fd}{9\left(m + \tfrac{1}{3}M\right)}\right) = \frac{MFd}{3\left(m + \tfrac{1}{3}M\right)} = \boxed{\frac{MFd}{3m + M}}$$

(*c*) Express the total kinetic energy of the system and simplify to obtain:

$$K_{\text{tot}} = K_{\text{S}} + K_{\text{C}} = \frac{mFd}{m+\frac{1}{3}M} + \frac{MFd}{3\left(m+\frac{1}{3}M\right)} = \frac{(3m+M)}{3\left(m+\frac{1}{3}M\right)}Fd = \boxed{Fd}$$

99 ••• [SSM] Two large gears that are being designed as part of a large machine and are shown in Figure 9-66; each is free to rotate about a fixed axis through its center. The radius and moment of inertia of the smaller gear are 0.50 m and 1.0 kg·m^2, respectively, and the radius and moment of inertia of the larger gear are 1.0 m and 16 kg·m^2, respectively. The lever attached to the smaller gear is 1.0 m long and has a negligible mass. (*a*) If a worker will typically apply a force of 2.0 N to the end of the lever, as shown, what will be the angular accelerations of the two gears? (*b*) Another part of the machine (not shown) will apply a force tangentially to the outer edge of the larger gear to temporarily keep the gear system from rotating. What should the magnitude and direction of this force (clockwise or counterclockwise) be?

Picture the Problem The forces responsible for the rotation of the gears are shown in the diagram to the right. The forces acting through the centers of mass of the two gears have been omitted because they produce no torque. We can apply Newton's second law in rotational form to obtain the equations of motion of the gears and the not slipping condition to relate their angular accelerations.



(*a*) Apply $\sum\tau = I\alpha$ to the gears to obtain their equations of motion:

$$2.0\ \text{N}\cdot\text{m} - FR_1 = I_1\alpha_1 \qquad (1)$$

and

$$FR_2 = I_2\alpha_2 \qquad (2)$$

where F is the force keeping the gears from slipping with respect to each other.

Because the gears do not slip relative to each other, the tangential accelerations of the points where they are in contact must be the same:

$$R_1\alpha_1 = R_2\alpha_2$$

or

$$\alpha_2 = \frac{R_1}{R_2}\alpha_1 = \tfrac{1}{2}\alpha_1 \qquad (3)$$

Divide equation (1) by R_1 to obtain:

$$\frac{2.0\ \text{N}\cdot\text{m}}{R_1} - F = \frac{I_1}{R_1}\alpha_1$$

Divide equation (2) by R_2 to obtain:

$$F = \frac{I_2}{R_2}\alpha_2$$

Adding these equations yields:

$$\frac{2.0\ \text{N}\cdot\text{m}}{R_1} = \frac{I_1}{R_1}\alpha_1 + \frac{I_2}{R_2}\alpha_2$$

Use equation (3) to eliminate α_2:

$$\frac{2.0\ \text{N}\cdot\text{m}}{R_1} = \frac{I_1}{R_1}\alpha_1 + \frac{I_2}{2R_2}\alpha_1$$

Solving for α_1 yields:

$$\alpha_1 = \frac{2.0\ \text{N}\cdot\text{m}}{I_1 + \frac{R_1}{2R_2}I_2}$$

Substitute numerical values and evaluate α_1:

$$\alpha_1 = \frac{2.0\ \text{N}\cdot\text{m}}{1.0\ \text{kg}\cdot\text{m}^2 + \frac{0.50\ \text{m}}{2(1.0\ \text{m})}\left(16\ \text{kg}\cdot\text{m}^2\right)}$$
$$= 0.400\ \text{rad/s}^2 = \boxed{0.40\ \text{rad/s}^2}$$

Use equation (3) to evaluate α_2:

$$\alpha_2 = \tfrac{1}{2}\left(0.400\ \text{rad/s}^2\right) = \boxed{0.20\ \text{rad/s}^2}$$

(*b*) To counterbalance the 2.0-N·m torque, a counter torque of 2.0 N·m must be applied to the first gear:

$$2.0\ \text{N}\cdot\text{m} - FR_1 = 0 \Rightarrow F = \frac{2.0\ \text{N}\cdot\text{m}}{R_1}$$

Substitute numerical values and evaluate F:

$$F = \frac{2.0\ \text{N}\cdot\text{m}}{0.50\ \text{m}} = \boxed{4.0\ \text{N, clockwise}}$$

100 ••• As the chief design engineer for a major toy company, you are in charge of designing a "loop-the-loop" toy for youngsters. The idea, as shown in Figure 9-67, is that a ball of mass m and radius r will roll down an inclined track and around the loop without slipping. The ball starts from rest at a height h above the tabletop that supports the whole track. The loop radius is R. Determine the minimum height h, in terms of R and r, for which the ball will remain in contact with the track during the whole of its loop-the-loop journey. (Do not neglect the size of the ball's radius when doing this calculation.)

Picture the Problem Choose $U_g = 0$ at the bottom of the loop and let the system include the ball, the track, and Earth. We can apply conservation of energy to this system to relate h to the speed of the ball v at the top of the "loop-to-loop", the radius r of the ball, and the radius R of the "loop-to-loop." We can then apply Newton's second law to the ball at the top of the loop to eliminate v.

Apply conservation of energy to the system to obtain:

$$W_{\text{ext}} = \Delta K + \Delta U_{\text{g}}$$

and, because $W_{\text{ext}} = 0$,

$$\Delta K_{\text{trans}} + \Delta K_{\text{rot}} + \Delta U_{\text{g}} = 0$$

Substituting for ΔK_{trans}, ΔK_{rot}, and ΔU_{g} yields:

$$K_{\text{trans,f}} - K_{\text{trans, i}} + K_{\text{rot,f}} - K_{\text{rot,i}} + U_{\text{g,f}} - U_{\text{g,i}} = 0$$

Because $K_{\text{trans,i}} = K_{\text{rot,i}} = 0$:

$$K_{\text{trans,f}} + K_{\text{rot,f}} + U_{\text{g,f}} - U_{\text{g,i}} = 0$$

Substitute for $K_{\text{trans,f}}$, $K_{\text{rot,f}}$, $U_{\text{g,f}}$, and $U_{\text{g,i}}$ to obtain:

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2 + mg(2R - r) - mgh = 0$$

Noting that, because the ball rolls without slipping, $v = r\omega$ and that $I_{\text{sphere}} = \tfrac{2}{5}mr^2$, substitute to obtain:

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(\tfrac{2}{5}mr^2\right)\left(\frac{v}{r}\right)^2 + mg(2R - r) - mgh = 0 \Rightarrow h = \frac{7v^2}{10g} + 2R - r$$

Noting that, for the minimum speed for which the ball remains in contact with the track at the top of the loop the centripetal force is the gravitational force, apply Newton's second law to the ball to obtain:

$$mg = m\frac{v^2}{R - r} \Rightarrow v^2 = g(R - r)$$

Substituting for v^2 and simplifying yields:

$$h = \frac{7g(R - r)}{10g} + 2R - r$$
$$= \boxed{2.7R - 1.7r}$$

Rolling With Slipping

101 •• A bowling ball of mass M and radius R is released so that at the instant it touches the floor it is moving horizontally with a speed v_0 and is not rotating. It slides for a time t_1 a distance s_1 before it begins to roll without slipping. (*a*) If μ_{k} is the coefficient of kinetic friction between the ball and the floor, find s_1, t_1, and the final speed v_1 of the ball. (*b*) Find the ratio of the final kinetic energy to the initial kinetic energy of the ball. (*c*) Evaluate s_1, t_1, and v_1 for $v_0 = 8.0$ m/s and $\mu_{\text{k}} = 0.060$.

Picture the Problem Part (*a*) of this problem is identical to Example 9-16. In Part (*b*) we can use the definitions of translational and rotational kinetic energy to find the ratio of the final and initial kinetic energies.

(*a*) From Example 9-19:

$$s_1 = \boxed{\frac{12}{49}\frac{v_0^2}{\mu_k g}}, t_1 = \boxed{\frac{2}{7}\frac{v_0}{\mu_k g}}, \text{ and}$$

$$v_1 = \tfrac{5}{2}\mu_k g t_1 = \boxed{\frac{5}{7}v_0}$$

(*b*) When the ball rolls without slipping, $v_1 = r\omega$. The final kinetic energy of the ball is given by:

$$K_f = K_{trans} + K_{rot} = \tfrac{1}{2}Mv_1^2 + \tfrac{1}{2}I\omega^2$$

Substituting for I and simplifying yields:

$$K_f = \tfrac{1}{2}Mv_1^2 + \tfrac{1}{2}\left(\tfrac{2}{5}Mr^2\right)\frac{v_1^2}{r^2} = \tfrac{7}{10}Mv_1^2 = \tfrac{5}{14}Mv_0^2$$

Express the ratio of the final and initial kinetic energies:

$$\frac{K_f}{K_i} = \frac{\frac{5}{14}Mv_0^2}{\frac{1}{2}Mv_0^2} = \boxed{\frac{5}{7}}$$

(*c*) Substitute numerical values in the expression from (*a*) and evaluate s_1:

$$s_1 = \frac{12}{49}\frac{(8.0\,\text{m/s})^2}{(0.060)(9.81\,\text{m/s}^2)} = \boxed{27\,\text{m}}$$

Substitute numerical values in the expression from (*a*) and evaluate t_1:

$$t_1 = \frac{2}{7}\frac{8.0\,\text{m/s}}{(0.060)(9.81\,\text{m/s}^2)} = \boxed{3.9\,\text{s}}$$

Substitute numerical values in the expression from (*a*) and evaluate v_1:

$$v_1 = \frac{5}{7}(8.0\,\text{m/s}) = \boxed{5.7\,\text{m/s}}$$

102 •• During a game of pool, the cue ball (a uniform sphere of radius r) is at rest on the horizontal pool table (Figure 9-68). You strike the ball horizontally with your cue stick, which delivers a large horizontal force of magnitude F_0 for a short time. The stick strikes the ball at a point a vertical height h above the tabletop. Assume the striking location is above the ball's center. Show that the ball's angular speed ω is related to the initial linear speed of its center of mass v_{cm} by $\omega = (5/2)v_{cm}(h - r)/r^2$. Estimate the ball's rotation rate just after the hit using reasonable estimates for h, r and v_{cm}.

Picture the Problem We can apply Newton's second law in rotational form and the impulse-momentum theorem to obtain two equations that we can solve simultaneously for ω.

Apply Newton's second law in rotational form to the cue ball:

$$F_0(h-r)=I_{\text{cm}}\alpha=\tfrac{2}{5}mr^2\frac{\Delta\omega}{\Delta t}$$
$$=\tfrac{2}{5}mr^2\frac{\omega}{\Delta t}$$

Solving for ω gives:

$$\omega=\frac{5F_0(h-r)\Delta t}{2mr^2} \qquad (1)$$

From the impulse-momentum theorem:

$$F_0\Delta t=\Delta p=mv_{\text{cm}}\Rightarrow\Delta t=\frac{mv_{\text{cm}}}{F_0}$$

Substitute for Δt in equation (1) and simplify to obtain:

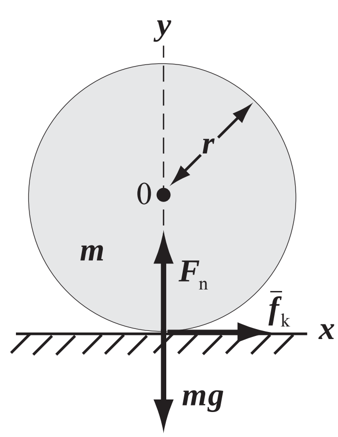
$$\omega=\frac{5F_0(h-r)\dfrac{mv_{\text{cm}}}{F_0}}{2mr^2}=\boxed{\frac{5v_{\text{cm}}(h-r)}{2r^2}}$$

Assume that $v_{\text{cm}}\approx 1.0$ m/s, $r\approx 4.0$ cm, and $h\approx 6.0$ cm, to estimate ω:

$$\omega=\frac{5(1.0\text{ m/s})(6.0\text{ cm}-4.0\text{ cm})}{2(4.0\text{ cm})^2}$$
$$\approx\boxed{30\text{ rad/s}}$$

103 •• A uniform solid sphere is set rotating about a horizontal axis at an angular speed ω_0 and then is placed on the floor with its center of mass at rest. If the coefficient of kinetic friction between the sphere and the floor is μ_k, find the speed of the center of mass of the sphere when the sphere begins to roll without slipping.

Picture the Problem The angular speed of the rotating sphere will decrease until the condition for rolling without slipping is satisfied and then it will begin to roll. The force diagram shows the forces acting on the sphere. We can apply Newton's second law to the sphere and use the condition for rolling without slipping to find the speed of the center of mass when the sphere begins to roll without slipping.



Relate the velocity of the sphere when it begins to roll to its acceleration at that moment and the elapsed time:

$$v = a\Delta t \qquad (1)$$

Apply Newton's second law to the sphere to obtain:

$$\sum F_x = f_k = ma\ , \qquad (2)$$

$$\sum F_y = F_n - mg = 0\,, \qquad (3)$$

and

$$\sum \tau_0 = f_k r = I_0\alpha \qquad (4)$$

Using the definition of f_k and F_n from equation (3), substitute in equation (2) and solve for a:

$$a = \mu_k g$$

Substitute in equation (1) to obtain:

$$v = a\Delta t = \mu_k g\Delta t \qquad (5)$$

Solving for α in equation (4) yields:

$$\alpha = \frac{f_k r}{I_0} = \frac{mar}{\frac{2}{5}mr^2} = \frac{5}{2}\frac{\mu_k g}{r}$$

Express the angular speed of the sphere when it has been moving for a time Δt:

$$\omega = \omega_0 - \alpha\,\Delta t = \omega_0 - \frac{5\mu_k g}{2r}\Delta t \quad (6)$$

Express the condition that the sphere rolls without slipping:

$$v = r\omega$$

Substitute from equations (5) and (6) and solve for the elapsed time until the sphere begins to roll:

$$\Delta t = \frac{2}{7}\frac{r\omega_0}{\mu_k g}$$

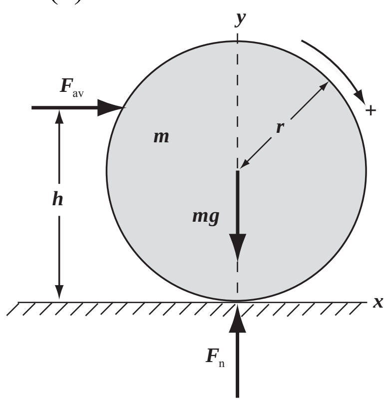
Use equation (5) to find v when the sphere begins to roll:

$$v = \mu_k g\Delta t = \frac{2}{7}\frac{r\omega_0\mu_k g}{\mu_k g} = \boxed{\frac{2r\omega_0}{7}}$$

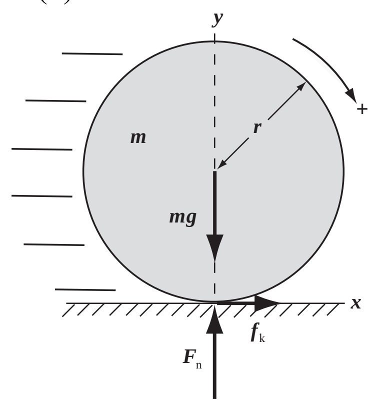
104 •• A uniform solid ball that has a mass of 20 g and a radius of 5.0 cm rests on a horizontal surface. A sharp force is applied to the ball in a horizontal direction 9.0 cm above the horizontal surface. During impact the force increases linearly from 0 N to 40 kN in 1.0×10^{-4} s, and then decreases linearly to 0 N in 1.0×10^{-4} s. (*a*) What is the speed of the ball just after impact? (*b*) What is the angular speed of the ball after impact? (*c*) What is the speed of the ball when it begins to roll without slipping? (*d*) How far does the ball travel along the surface before it begins to roll without slipping? Assume that $\mu_k = 0.50$.

Picture the Problem (*a*) The sharp force delivers a translational impulse to the ball that changes its linear momentum. We can use the impulse-momentum theorem to find the speed of the ball after impact. (*b*) We can find the angular speed of the ball after impact by applying Newton's second law in rotational form. Because the ball has a forward spin, the friction force is in the direction of motion and will cause the ball's translational speed to increase. In Parts (*c*) and (*d*) we can apply Newton's second law to the ball to obtain equations describing both the translational and rotational motion of the ball. We can then solve these equations to find the constant accelerations that allow us to apply constant-acceleration equations to find the velocity of the ball when it begins to roll and its sliding time.

(*a*) and (*b*)



(*c*) and (*d*)



(*a*) Apply the impulse-momentum theorem to the ball. The frictional force can be neglected during impact:

$$I = F_{av}\Delta t = \Delta p = mv_0$$

Solving for v_0 yields:

$$v_0 = \frac{F_{av}\Delta t}{m} \qquad (1)$$

Substitute numerical values and evaluate v_0:

$$v_0 = \frac{(20\,\text{kN})(2.0\times10^{-4}\ \text{s})}{0.020\,\text{kg}} = \boxed{2.0\times10^{2}\ \text{m/s}}$$

(*b*) Referring to the force diagram for (*a*) and (*b*), apply Newton's second law in rotational form to the ball to obtain:

$$F_{av}(h-r) = I_{cm}\alpha = I_{cm}\frac{\omega_0}{\Delta t}$$

Solving for ω_0 yields:

$$\omega_0 = \frac{F_{\text{av}}(h-r)\Delta t}{I_{\text{cm}}} = \frac{F_{\text{av}}(h-r)\Delta t}{\frac{2}{5}mr^2}$$

Solve equation (1) for Δt:

$$\Delta t = \frac{mv_0}{F_{\text{av}}}$$

Substitute for Δt and simplify to obtain:

$$\omega_0 = \frac{F_{\text{av}}(h-r)\frac{mv_0}{F_{\text{av}}}}{\frac{2}{5}mr^2} = \frac{5v_0(h-r)}{2r^2}$$

Substitute numerical values and evaluate ω_0:

$$\omega_0 = \frac{5(2.0\times10^2\ \text{m/s})(0.090\,\text{m} - 0.050\,\text{m})}{2(.050\,\text{m})^2} = \boxed{8.0\times10^3\ \text{rad/s}}$$

(*c*) Use a constant-acceleration equation to relate the speed of the ball to the acceleration and the time:

$$v_{\text{cm}\,x} = v_0 + a_{\text{cm}\,x}t \qquad (1)$$

To determine the direction of the frictional force we first determine whether the angular speed after impact is less than, equal to, or greater than the angular speed v_0/r for rolling without slipping:

$$\frac{v_0}{r} = \frac{2.0\times10^2\ \text{m/s}}{0.050\ \text{m}} = 4.0\times10^3\ \text{rad/s}$$

If the angular speed ω_0 is greater than v_0/r, then the frictional force will be in the forward direction, as shown in the force diagram for (*c*) and (*d*):

$$\omega_0 > \frac{v_0}{r}$$

Referring to the force diagram for (*c*) and (*d*), apply Newton's second law to the ball to obtain:

$$\sum F_x = f_{\text{k}} = ma_{\text{cm}\,x}, \qquad (2)$$

$$\sum F_y = F_{\text{n}} - mg = 0, \qquad (3)$$

and

$$\sum \tau_{\text{cm}} = -f_{\text{k}}r = I_{\text{cm}}\alpha \qquad (4)$$

Substituting for f_{k} in equation (2) gives:

$$\mu_{\text{k}}mg = ma_{\text{cm}\,x} \Rightarrow a_{\text{cm}\,x} = \mu_{\text{k}}g$$

Substitute for $a_{\text{cm}\,x}$ in equation (1) to obtain:

$$v_{\text{cm}\,x} = v_0 + \mu_{\text{k}} gt \qquad (5)$$

Solving for α in equation (4) yields:

$$\alpha = -\frac{f_{\text{k}} r}{I_{\text{cm}}} = -\frac{\mu_{\text{k}} mgr}{\frac{2}{5}mr^2} = -\frac{5\mu_{\text{k}} g}{2r}$$

Use a constant-acceleration equation to relate the angular speed of the ball to the angular acceleration and the time:

$$\omega = \omega_0 + \alpha t = \omega_0 - \frac{5\mu_{\text{k}} g}{2r} t \qquad (6)$$

When the ball rolls without slipping:

$$v_{\text{cm}\,x} = r\omega = r\left(\omega_0 - \frac{5\mu_{\text{k}} g}{2r} t\right) = r\omega_0 - \frac{5\mu_{\text{k}} g}{2} t \qquad (7)$$

Equate equations (5) and (7) to obtain:

$$r\omega_0 - \frac{5\mu_{\text{k}} g}{2} t = v_0 + \mu_{\text{k}} gt$$

Solve for the time t at which $v_{\text{cm}\,x} = r\omega$:

$$t = \frac{2(r\omega_0 - v_0)}{7\mu_{\text{k}} g}$$

Substitute numerical values and evaluate t:

$$t = \frac{2\left[(0.050\text{ m})\left(8.0\times10^3\text{ rad/s}\right) - 2.0\times10^2\text{ m/s}\right]}{7(0.50)\left(9.81\text{ m/s}^2\right)} = 11.65\text{ s}$$

Substitute numerical values in equation (5) and evaluate $v_{\text{cm}\,x}(11.65\text{ s})$:

$$v_{\text{cm}\,x}(11.65\text{ s}) = 2.0\times10^2\text{ m/s} + (0.50)\left(9.81\text{ m/s}^2\right)(11.65\text{ s}) = 2.571\times10^2\text{ m/s} = \boxed{2.6\times10^2\text{ m/s}}$$

(*d*) The distance traveled in time t is:

$$\Delta x = v_0 t + \tfrac{1}{2} a_{\text{cm}} t^2 = v_0 t + \tfrac{1}{2}\mu_{\text{k}} g t^2$$

Substitute numerical values and evaluate $\Delta x(11.65\text{ s})$:

$$\Delta x(11.65\text{ s}) = \left(2.0\times10^2\text{ m/s}\right)(11.65\text{ s}) + \tfrac{1}{2}(0.50)\left(9.81\text{ m/s}^2\right)(11.65\text{ s})^2 = \boxed{3.0\text{ km}}$$

105 •• **[SSM]** A 0.16-kg billiard ball whose radius is 3.0 cm is given a sharp blow by a cue stick. The applied force is horizontal and the line of action of the force passes through the center of the ball. The speed of the ball just after the

blow is 4.0 m/s, and the coefficient of kinetic friction between the ball and the billiard table is 0.60. (*a*) How long does the ball slide before it begins to roll without slipping? (*b*) How far does it slide? (*c*) What is its speed once it begins rolling without slipping?

Picture the Problem Because the impulse is applied through the center of mass, $\omega_0 = 0$. We can use the results of Example 9-16 to find the rolling time without slipping, the distance traveled to rolling without slipping, and the velocity of the ball once it begins to roll without slipping.

(*a*) From Example 9-19 we have:

$$t_1 = \frac{2}{7}\frac{v_0}{\mu_k g}$$

Substitute numerical values and evaluate t_1:

$$t_1 = \frac{2}{7}\frac{4.0\,\text{m/s}}{(0.60)(9.81\,\text{m/s}^2)} = \boxed{0.19\,\text{s}}$$

(*b*) From Example 9-19 we have:

$$s_1 = \frac{12}{49}\frac{v_0^2}{\mu_k g}$$

Substitute numerical values and evaluate s_1:

$$s_1 = \frac{12}{49}\frac{(4.0\,\text{m/s})^2}{(0.60)(9.81\,\text{m/s}^2)} = \boxed{0.67\,\text{m}}$$

(*c*) From Example 9-16 we have:

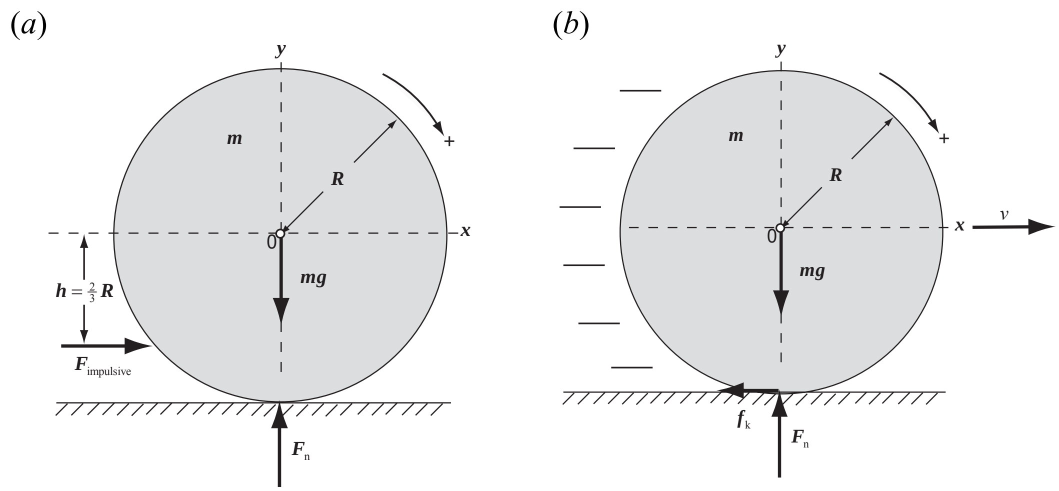
$$v_1 = \frac{5}{7}v_0$$

Substitute numerical values and evaluate v_1:

$$v_1 = \frac{5}{7}(4.0\,\text{m/s}) = \boxed{2.9\,\text{m/s}}$$

106 •• A billiard ball that is initially at rest is given a sharp blow by a cue stick. The force is horizontal and is applied at a distance $2R/3$ below the centerline, as shown in Figure 9-69. The speed of the ball just after the blow is v_0 and the coefficient of kinetic friction between the ball and the billiard table is μ_k. (*a*) What is the angular speed of the ball just after the blow? (*b*) What is the speed of the ball once it begins to roll without slipping? (*c*) What is the kinetic energy of the ball just after the hit?

Picture the Problem Because the impulsive force is applied below the center line, the ball will have a backward spin and the direction of the friction force is opposite the direction of motion. This will cause the ball's translational speed to decrease. We'll use the impulse-momentum theorem and Newton's second law in rotational form to find the linear and rotational speeds and accelerations of the ball and constant-acceleration equations to relate these quantities to each other and to the elapsed time-to-rolling without slipping.



(*a*) Apply Newton's second law in rotational form to the ball to obtain:

$$\sum \tau_0 = F_{av}(h-R) = I_{cm}\alpha = I_{cm}\frac{\omega_0}{\Delta t}$$

Solving for ω_0 yields:

$$\omega_0 = \frac{F_{av}(h-R)\Delta t}{I_{cm}} = \frac{F_{av}(h-R)\Delta t}{\frac{2}{5}mr^2}$$

Because $F_{av}\Delta t = mv_0$:

$$\Delta t = \frac{mv_0}{F_{av}}$$

Substitute for Δt and simplify to obtain:

$$\omega_0 = \frac{F_{av}(h-R)\frac{mv_0}{F_{av}}}{\frac{2}{5}mR^2} = \boxed{\frac{5v_0(h-R)}{2R^2}}$$

(*b*) Apply Newton's second law to the ball to obtain:

$$\sum \tau_0 = f_k R = I_{cm}\alpha\,, \qquad (1)$$

$$\sum F_y = F_n - mg = 0\,, \qquad (2)$$

and

$$\sum F_x = -f_k = ma \qquad (3)$$

Substitute for f_k in equation (1), and solve for α:

$$\alpha = \frac{\mu_k mgR}{I_{cm}} = \frac{\mu_k mgR}{\frac{2}{5}mR^2} = \frac{5\mu_k g}{2R}$$

Using a constant-acceleration equation, relate the angular speed of the ball to its acceleration:

$$\omega = \omega_0 + \alpha\Delta t = \omega_0 + \frac{5\mu_k g}{2R}\Delta t$$

Substituting for f_k in equation (3) and solving for a gives:

$$a = -\mu_k g$$

Using a constant-acceleration equation, relate the speed of the ball to its acceleration:

$$v = v_0 + a\Delta t = v_0 - \mu_k g\Delta t \qquad (4)$$

Impose the condition for rolling without slipping to obtain:

$$R\left(\omega_0 + \frac{5\mu_k g}{2R}\Delta t\right) = v_0 - \mu_k g\Delta t$$

Solving for Δt yields:

$$\Delta t = \frac{16}{21}\frac{v_0}{\mu_k g}$$

Substitute in equation (4) to obtain:

$$v = v_0 - \mu_k g\left(\frac{16}{21}\frac{v_0}{\mu_k g}\right) = \boxed{\frac{5}{21}v_0}$$

(*c*) Express the initial kinetic energy of the ball and simplify to obtain:

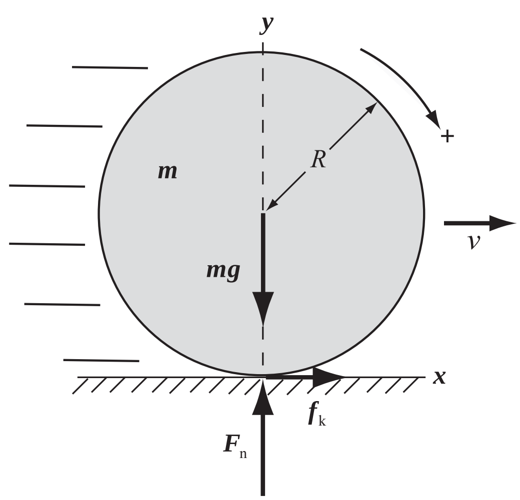
$$K_i = K_{trans} + K_{rot} = \tfrac{1}{2}mv_0^2 + \tfrac{1}{2}I\omega_0^2$$

$$= \tfrac{1}{2}mv_0^2 + \tfrac{1}{2}\left(\tfrac{2}{5}mR^2\right)\left(\frac{5v_0}{3R}\right)^2$$

$$= \boxed{\frac{19}{18}mv_0^2}$$

107 •• A bowling ball of radius R has an initial speed v_0 down the lane and a forward spin $\omega_0 = 3v_0/R$ just after its release. The coefficient of kinetic friction is μ_k. (*a*) What is the speed of the ball just as it begins rolling without slipping? (*b*) For how long a time does the ball slide before it begins rolling without slipping? (*c*) What distance does the ball slide down the lane before it begins rolling without slipping?

Picture the Problem The figure shows the forces acting on the bowling during the sliding phase of its motion. Because the ball has a forward spin, the friction force is in the direction of motion and will cause the ball's translational speed to increase. We'll apply Newton's second law to find the linear and rotational velocities and accelerations of the ball and constant-acceleration equations to relate these quantities to each other and to the elapsed time to rolling without slipping.



(*a*) and (*b*) Relate the velocity of the ball when it begins to roll to its acceleration and the elapsed time:

$$v = v_0 + a\Delta t \qquad (1)$$

Apply Newton's second law to the ball:

$$\sum F_x = f_k = ma\,, \qquad (2)$$

$$\sum F_y = F_n - mg = 0\,, \qquad (3)$$

and

$$\sum \tau_0 = -f_k R = I_0\alpha \qquad (4)$$

Substituting for f_k in equation (2) and solving for a gives:

$$a = \mu_k g$$

Substitute in equation (1) to obtain:

$$v = v_0 + a\Delta t = v_0 + \mu_k g\Delta t \qquad (5)$$

Solve for α in equation (4):

$$\alpha = -\frac{f_k R}{I_0} = -\frac{maR}{\frac{2}{5}mR^2} = -\frac{5}{2}\frac{\mu_k g}{R}$$

Relate the angular speed of the ball to its acceleration:

$$\omega = \omega_0 - \frac{5}{2}\frac{\mu_k g}{R}\Delta t$$

Apply the condition for rolling without slipping and simplify to obtain:

$$v = R\omega = R\left(\omega_0 - \frac{5}{2}\frac{\mu_k g}{R}\Delta t\right)$$

$$= R\left(\frac{3v_0}{R} - \frac{5}{2}\frac{\mu_k g}{R}\Delta t\right) \qquad (6)$$

$$= 3v_0 - \frac{5}{2}\mu_k g\Delta t$$

Equate equations (5) and (6) and solve for Δt:

$$\Delta t = \boxed{\frac{4}{7}\frac{v_0}{\mu_k g}}$$

Substitute for Δt in equation (6) to obtain:

$$v = \boxed{\frac{11}{7}v_0}$$

(*c*) Relate Δx to the average speed of the ball and the time it moves before beginning to roll without slipping:

$$\Delta x = v_{av}\Delta t = \tfrac{1}{2}(v_0 + v)\Delta t$$

Substitute for $v_0 + v$ and Δt and simplify to obtain:

$$\Delta x = \tfrac{1}{2}\left(v_0 + \frac{11}{7}v_0\right)\left(\frac{4v_0}{7\mu_k g}\right) = \boxed{\frac{36}{49}\frac{v_0^2}{\mu_k g}}$$

General Problems

108 •• The radius of a small playground merry-go-round is 2.2 m. To start it rotating, you wrap a rope around its perimeter and pull with a force of 260 N for 12 s. During this time, the merry-go-round makes one complete rotation. Neglect any effects of friction. (*a*) Find the angular acceleration of the merry-go-round. (*b*) What torque is exerted by the rope on the merry-go-round? (*c*) What is the moment of inertia of the merry-go-round?

Picture the Problem The force you exert on the rope results in a net torque that accelerates the merry-go-round. The moment of inertia of the merry-go-round, its angular acceleration, and the torque you apply are related through Newton's second law.

(*a*) Using a constant-acceleration equation, relate the angular displacement of the merry-go-round to its angular acceleration and acceleration time:

$$\Delta\theta = \omega_0 \Delta t + \tfrac{1}{2}\alpha(\Delta t)^2$$

or, because $\omega_0 = 0$,

$$\Delta\theta = \tfrac{1}{2}\alpha(\Delta t)^2 \Rightarrow \alpha = \frac{2\Delta\theta}{(\Delta t)^2}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{2(2\pi\,\text{rad})}{(12\,\text{s})^2} = 0.0873\,\text{rad/s}^2 = \boxed{0.087\,\text{rad/s}^2}$$

(*b*) Use the definition of torque to obtain:

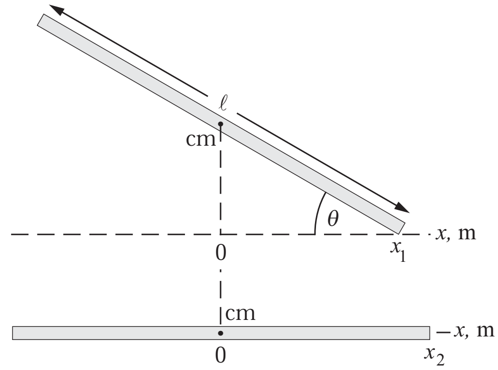
$$\tau = Fr = (260\,\text{N})(2.2\,\text{m}) = 572\,\text{N}\cdot\text{m} = \boxed{0.57\,\text{kN}\cdot\text{m}}$$

(*c*) Use Newton's second law to find the moment of inertia of the merry-go-round:

$$I = \frac{\tau_{\text{net}}}{\alpha} = \frac{572\,\text{N}\cdot\text{m}}{0.0873\,\text{rad/s}^2} = \boxed{6.6\times10^3\,\text{kg}\cdot\text{m}^2}$$

109 •• A uniform 2.00-m-long stick is raised at an angle of 30° to the horizontal above a sheet of ice. The bottom end of the stick rests on the ice. The stick is released from rest. The bottom of the stick remains in contact with the ice at all times. How far will the bottom end of the stick have traveled during the time the rest of the stick is falling to the ice? Assume that the ice is frictionless.

Picture the Problem Because there are no horizontal forces acting on the stick, the center of mass of the stick will not move in the horizontal direction. Choose a coordinate system in which the origin is at the horizontal position of the center of mass. The diagram shows the stick in its initial raised position and when it has fallen to the ice.



Express the displacement of the right end of the stick Δx as the difference between the position coordinates x_1 and x_2:

$$\Delta x = x_2 - x_1 \qquad (1)$$

Using trigonometry, find the initial coordinate of the right end of the stick:

$$x_1 = \tfrac{1}{2}\ell\cos\theta = \tfrac{1}{2}(2.00\,\text{m})\cos 30° = 0.866\,\text{m}$$

Because the center of mass has not moved horizontally:

$$x_2 = \tfrac{1}{2}\ell = 1.00\,\text{m}$$

Substitute for x_1 and x_2 in equation (1) to find the displacement of the right end of the stick:

$$\Delta \mathbf{x} = 1.00\,\text{m} - 0.866\,\text{m} = \boxed{13\,\text{cm}}$$

110 •• A uniform 5.0-kg disk that has a 0.12-m radius is pivoted so that it rotates freely about its axis (Figure 9-70). A string wrapped around the disk is pulled with a force equal to 20 N. (*a*) What is the torque being exerted by this force about the rotation axis? (*b*) What is the angular acceleration of the disk? (*c*) If the disk starts from rest, what is its angular speed after 5.0 s? (*d*) What is its kinetic energy after the 5.0 s? (*e*) What is the angular displacement of the disk during the 5.0 s? (*f*) Show that the work done by the torque, $\tau\,\Delta\theta$, equals the kinetic energy.

Picture the Problem The force applied to the string results in a torque about the center of mass of the disk that accelerates it. We can relate these quantities to the moment of inertia of the disk through Newton's second law and then use constant-acceleration equations to find the disks angular speed the angle through which it has rotated in a given period of time. The disk's rotational kinetic energy can be found from its definition.

(*a*) Use the definition of torque to obtain:

$$\tau = FR = (20\,\text{N})(0.12\,\text{m}) = 2.40\,\text{N}\cdot\text{m} = \boxed{2.4\,\text{N}\cdot\text{m}}$$

(*b*) Use Newton's second law to express the angular acceleration of the disk in terms of the net torque acting on it and its moment of inertia:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{\tau_{\text{net}}}{\frac{1}{2}MR^2} = \frac{2\tau_{\text{net}}}{MR^2}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{2(2.40\,\text{N}\cdot\text{m})}{(5.0\,\text{kg})(0.12\,\text{m})^2} = 66.7\,\text{rad/s}^2$$
$$= \boxed{67\,\text{rad/s}^2}$$

(*c*) Using a constant-acceleration equation, relate the angular speed of the disk to its angular acceleration and the elapsed time:

$$\omega = \omega_0 + \alpha\Delta t$$

or, because $\omega_0 = 0$,

$$\omega = \alpha\Delta t$$

Substitute numerical values and evaluate ω:

$$\omega = (66.7\,\text{rad/s}^2)(5.0\,\text{s}) = 333\,\text{rad/s}$$
$$= \boxed{3.3\times10^2\ \text{rad/s}}$$

(*d*) Use the definition of rotational kinetic energy to obtain:

$$K_{\text{rot}} = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\omega^2$$
$$= \tfrac{1}{4}MR^2\omega^2$$

Substitute numerical values and evaluate K_{rot}:

$$K_{\text{rot}} = \tfrac{1}{4}(5.0\,\text{kg})(0.12\,\text{m})^2(333\,\text{rad/s})^2$$
$$= \boxed{2.0\,\text{kJ}}$$

(*e*) Using a constant-acceleration equation, relate the angle through which the disk turns to its angular acceleration and the elapsed time:

$$\Delta\theta = \omega_0\Delta t + \tfrac{1}{2}\alpha(\Delta t)^2$$

or, because $\omega_0 = 0$,

$$\Delta\theta = \tfrac{1}{2}\alpha(\Delta t)^2$$

Substitute numerical values and evaluate $\Delta\theta$:

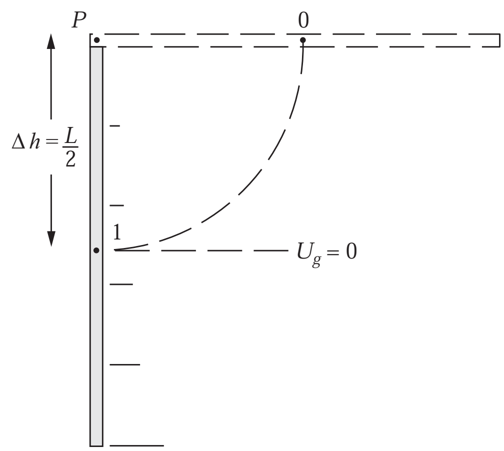
$$\Delta\theta = \tfrac{1}{2}(66.7\,\text{rad/s}^2)(5.0\,\text{s})^2$$
$$= \boxed{8.3\times10^2\ \text{rad}}$$

(*f*) Substitute for I and ω^2 in the expression for K and simplify to obtain:

$$K = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}\left(\frac{\tau}{\alpha}\right)(\alpha\Delta t)^2 = \tfrac{1}{2}\alpha\tau(\Delta t)^2$$
$$= \boxed{\tau\Delta\theta}$$

111 •• A uniform 0.25-kg thin rod that has a 80-cm length is free to rotate about a fixed horizontal axis perpendicular to, and through one end, of the rod. It is held horizontal and released. Immediately after it is released, what is (*a*) the acceleration of the center of the rod, and (*b*) the initial acceleration of the free end of the rod? (*c*) What is the speed of the center of mass of the rod when the rod is (momentarily) vertical.

Picture the Problem The diagram shows the rod in its initial horizontal position and then, later, as it swings through its vertical position. The center of mass is denoted by the numerals 0 and 1. Let the length of the rod be represented by L and its mass by m. We can use Newton's second law in rotational form to find, first, the angular acceleration of the rod and then, from α, the acceleration of any point on the rod. We can use conservation of energy to find the angular speed of the center of mass of the rod when it is vertical and then use this value to find its linear velocity.



(*a*) Relate the acceleration of the center of the rod to the angular acceleration of the rod:

$$a = \ell\alpha = \frac{L}{2}\alpha$$

Use Newton's second law to relate the torque about the suspension point of the rod (exerted by the weight of the rod) to the rod's angular acceleration:

$$\alpha = \frac{\tau}{I_{\mathrm{P}}} = \frac{Mg\frac{L}{2}}{\frac{1}{3}ML^2} = \frac{3g}{2L}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{3(9.81\,\mathrm{m/s^2})}{2(0.80\,\mathrm{m})} = 18.4\,\mathrm{rad/s^2}$$

Substitute numerical values and evaluate a:

$$a = \tfrac{1}{2}(0.80\,\mathrm{m})(18.4\,\mathrm{rad/s^2}) = \boxed{7.4\,\mathrm{m/s^2}}$$

(*b*) Relate the acceleration of the end of the rod to α:

$$a_{\text{end}} = L\alpha$$

Substitute numerical values and evaluate a_{end}:

$$a_{\text{end}} = (0.80\,\text{m})(18.4\,\text{rad/s}^2) = \boxed{15\,\text{m/s}^2}$$

(*c*) Relate the linear velocity of the center of mass of the rod to its angular speed as it passes through the vertical:

$$v = \omega\Delta h = \tfrac{1}{2}\omega L \qquad (1)$$

Use conservation of energy to relate the changes in the kinetic and potential energies of the rod as it swings from its initial horizontal orientation through its vertical orientation:

$$\Delta K + \Delta U = K_1 - K_0 + U_1 - U_0 = 0$$

or, because $K_0 = U_1 = 0$,

$$K_1 - U_0 = 0$$

Substitute for K_1 and U_0 to obtain:

$$\tfrac{1}{2}I_{\text{P}}\omega^2 - mg\Delta h = 0$$

Substituting for I_{P} and Δh yields:

$$\tfrac{1}{2}\left(\tfrac{1}{3}mL^2\right)\omega^2 - mg\left(\tfrac{1}{2}L\right) = 0 \Rightarrow \omega = \sqrt{\frac{3g}{L}}$$

Substituting for ω in equation (1) yields:

$$v = \tfrac{1}{2}L\sqrt{\frac{3g}{L}} = \tfrac{1}{2}\sqrt{3gL}$$

Substitute numerical values and evaluate v:

$$v = \tfrac{1}{2}\sqrt{3(9.81\,\text{m/s}^2)(0.80\,\text{m})} = \boxed{2.4\,\text{m/s}}$$

112 •• A marble of mass M and radius R rolls without slipping down the track on the left from a height h_1, as shown in Figure 9-71. The marble then goes up the *frictionless* track on the right to a height h_2. Find h_2.

Picture the Problem Let the zero of gravitational potential energy be at the bottom of the track. The initial potential energy of the marble is transformed into translational and rotational kinetic energy and gravitational potential energy (note that its center of mass is a distance R above the bottom of the track when it reaches the lowest point on the track) as it rolls down the track to its lowest point and then, because the portion of the track to the right is frictionless, into translational kinetic energy and, eventually, into gravitational potential energy.

Using conservation of energy, relate h_2 to the mechanical energy of the marble at the bottom of the track:

$$\Delta K + \Delta U = 0$$

or, because $K_f = 0$,

$$-K_i + U_f - U_i = 0$$

Substitute for K_i, U_f, and U_i to obtain:

$$-\tfrac{1}{2}Mv^2 + Mgh_2 - MgR = 0$$

Solving for h_2 gives:

$$h_2 = \frac{2gR + v^2}{2g} \qquad (1)$$

Using conservation of energy, relate h_1 to the energy of the marble at the bottom of the track:

$$\Delta K + \Delta U = 0$$

or, because $K_i = 0$,

$$K_{\text{f, trans}} + K_{\text{f, rot}} + U_f - U_i = 0$$

Substitute for the energies to obtain:

$$\tfrac{1}{2}Mv^2 + \tfrac{1}{2}I\omega^2 + MgR - Mgh_1 = 0$$

The moment of inertia of a sphere of mass M and radius R, about an axis through its center, is $\tfrac{2}{5}MR^2$:

$$\tfrac{1}{2}Mv^2 + \tfrac{1}{2}\left(\tfrac{2}{5}MR^2\right)\omega^2 + MgR - Mgh_1 = 0$$

Because the marble is rolling without slipping, $v = R\omega$ and:

$$\tfrac{1}{2}Mv^2 + \tfrac{1}{2}\left(\tfrac{2}{5}MR^2\right)\left(\frac{v}{R}\right)^2 + MgR - Mgh_1 = 0$$

Solve for v^2 to obtain:

$$v^2 = \tfrac{10}{7}g(h_1 - R)$$

Substitute for v^2 in equation (1) and simplify to obtain:

$$h_2 = \frac{2gR + \tfrac{10}{7}g(h_1 - R)}{2g} = \boxed{\tfrac{1}{7}(5h_1 + 2R)}$$

Remarks: If h_1, h_2 >> R, then our result becomes $h_2 = \tfrac{5}{7}h_1$.

113 •• **[SSM]** A uniform 120-kg disk with a radius equal to 1.4 m initially rotates with an angular speed of 1100 rev/min. A constant tangential force is applied at a radial distance of 0.60 m from the axis. (*a*) How much work must this force do to stop the wheel? (*b*) If the wheel is brought to rest in 2.5 min, what torque does the force produce? What is the magnitude of the force? (*c*) How many revolutions does the wheel make in these 2.5 min?

Picture the Problem To stop the wheel, the tangential force will have to do an amount of work equal to the initial rotational kinetic energy of the wheel. We can find the stopping torque and the force from the average power delivered by the

force during the slowing of the wheel. The number of revolutions made by the wheel as it stops can be found from a constant-acceleration equation.

(*a*) Relate the work that must be done to stop the wheel to its kinetic energy:

$$W=\tfrac{1}{2}I\omega^2=\tfrac{1}{2}\left(\tfrac{1}{2}mr^2\right)\omega^2=\tfrac{1}{4}mr^2\omega^2$$

Substitute numerical values and evaluate W:

$$W=\tfrac{1}{4}(120\,\text{kg})(1.4\,\text{m})^2\left[1100\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}\right]^2=780\,\text{kJ}=\boxed{7.8\times10^2\,\text{kJ}}$$

(*b*) Express the stopping torque in terms of the average power required:

$$P_\text{av}=\tau\omega_\text{av}\Rightarrow\tau=\frac{P_\text{av}}{\omega_\text{av}}$$

Substitute numerical values and evaluate τ:

$$\tau=\frac{\dfrac{780\,\text{kJ}}{(2.5\,\text{min})(60\,\text{s/min})}}{\dfrac{(1100\,\text{rev/min})(2\pi\,\text{rad/rev})(1\,\text{min}/60\,\text{s})}{2}}=90.3\,\text{N}\cdot\text{m}=\boxed{90\,\text{N}\cdot\text{m}}$$

Relate the stopping torque to the magnitude of the required force and evaluate F:

$$F=\frac{\tau}{R}=\frac{90.3\,\text{N}\cdot\text{m}}{0.60\,\text{m}}=\boxed{0.15\text{ kN}}$$

(*c*) Using a constant-acceleration equation, relate the angular displacement of the wheel to its average angular speed and the stopping time:

$$\Delta\theta=\omega_\text{av}\Delta t$$

Substitute numerical values and evaluate $\Delta\theta$:

$$\Delta\theta=\left(\frac{1100\,\text{rev/min}}{2}\right)(2.5\,\text{min})$$
$$=\boxed{1.4\times10^3\text{ rev}}$$

114 •• A day-care center has a merry-go-round that consists of a uniform 240-kg circular wooden platform 4.00 m in diameter. Four children run alongside the merry-go-round and push tangentially along the platform's circumference until, starting from rest, the merry-go-round is spinning at 2.14 rev/min. During the spin up: (*a*) If each child exerts a sustained force equal to 26 N, how far does each child run? (*b*) What is the angular acceleration of the merry-go-round?

(*c*) How much work does each child do? (*d*) What is the increase in the kinetic energy of the merry-go-round?

Picture the Problem The work done by the four children on the merry-go-round will change its kinetic energy. We can use the work-energy theorem to relate the work done by the children to the distance they ran and Newton's second law to find the angular acceleration of the merry-go-round.

(*a*) Use the work-kinetic energy theorem to relate the work done by the children to the kinetic energy of the merry-go-round:

$$W_{\text{net force}} = \Delta K = K_{\text{f}}$$

or

$$4F\Delta s = \tfrac{1}{2}I\omega^2$$

Substitute for I to obtain:

$$4F\Delta s = \tfrac{1}{2}\left(\tfrac{1}{2}mr^2\right)\omega^2 = \tfrac{1}{4}mr^2\omega^2$$

Solving for Δs yields:

$$\Delta s = \frac{mr^2\omega^2}{16F}$$

Substitute numerical values and evaluate Δs:

$$\Delta s = \frac{(240\,\text{kg})(2.00\,\text{m})^2\left[2.14\,\frac{\text{rev}}{\text{min}}\times\frac{1\,\text{min}}{60\,\text{s}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\right]^2}{16(26\,\text{N})}$$

$$= 0.116\,\text{m} = \boxed{0.12\,\text{m}}$$

(*b*) Apply Newton's second law to express the angular acceleration of the merry-go-round:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{4Fr}{\tfrac{1}{2}mr^2} = \frac{8F}{mr}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{8(26\,\text{N})}{(240\,\text{kg})(2.00\,\text{m})} = \boxed{0.43\,\text{rad/s}^2}$$

(*c*) Use the definition of work to relate the force exerted by each child to the distance over which that force is exerted:

$$W = F\Delta s = (26\,\text{N})(0.116\,\text{m}) = \boxed{3.0\,\text{J}}$$

(*d*) Relate the kinetic energy of the merry-go-round to the work that was done on it:

$$W_{\text{by net force}} = \Delta K = K_{\text{f}} - 0 = 4F\Delta s$$

Substitute numerical values and evaluate $W_{\text{by net force}}$:

$$W_{\text{by net force}} = 4(26\,\text{N})(0.116\,\text{m}) = \boxed{12\,\text{J}}$$

115 •• A uniform 1.5-kg hoop with a 65-cm radius has a string wrapped around its circumference and lies flat on a horizontal frictionless table. The free end of the string is pulled with a constant horizontal force equal to 5.0 N and the string does not slip on the hoop. (*a*) How far does the center of the hoop travel in 3.0 s? (*b*) What is the angular speed of the hoop after 3.0 s?

Picture the Problem Because the center of mass of the hoop is at its center, we can use Newton's second law to relate the acceleration of the hoop to the net force acting on it. The distance moved by the center of the hoop can be determined using a constant-acceleration equation, as can the angular speed of the hoop.

(*a*) Using a constant-acceleration equation, relate the distance the center of the hoop travels in 3.0 s to the acceleration of its center of mass:

$$\Delta s = \tfrac{1}{2} a_{\text{cm}} (\Delta t)^2$$

Relate the acceleration of the center of mass of the hoop to the net force acting on it:

$$a_{\text{cm}} = \frac{F_{\text{net}}}{m}$$

Substitute for a_{cm} to obtain:

$$\Delta s = \frac{F(\Delta t)^2}{2m}$$

Substitute numerical values and evaluate Δs:

$$\Delta s = \frac{(5.0\,\text{N})(3.0\,\text{s})^2}{2(1.5\,\text{kg})} = \boxed{15\,\text{m}}$$

(*b*) Relate the angular speed of the hoop to its angular acceleration and the elapsed time:

$$\omega = \alpha\,\Delta t$$

Use Newton's second law to relate the angular acceleration of the hoop to the net torque acting on it:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{FR}{mR^2} = \frac{F}{mR}$$

Substitute for α in the expression for ω to obtain:

$$\omega = \frac{F\Delta t}{mR}$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{(5.0\,\text{N})(3.0\,\text{s})}{(1.5\,\text{kg})(0.65\,\text{m})} = \boxed{15\,\text{rad/s}}$$

116 •• A hand-driven grinding wheel is a uniform 60-kg disk with a 45-cm radius. It has a handle of negligible mass 65 cm from the rotation axis. A compact 25-kg load is attached to the handle when it is at the same height as the horizontal rotation axis. Ignoring the effects of friction, find (*a*) the initial angular acceleration of the wheel, and (*b*) the maximum angular speed of the wheel.

Picture the Problem Let R represent the radius of the grinding wheel, M its mass, r the radius of the handle, and m the mass of the load attached to the handle. In the absence of information to the contrary, we'll treat the 25-kg load as though it were concentrated at a point. Let the zero of gravitational potential energy be where the 25-kg load is at its lowest point. We'll apply Newton's second law and the conservation of mechanical energy to determine the initial angular acceleration and the maximum angular speed of the wheel.

(*a*) Use Newton's second law to relate the acceleration of the wheel to the net torque acting on it:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{mgr}{I}$$

The moment of inertia of the wheel-and-load system is the sum of their moments of inertia. Substituting for I yields:

$$\alpha = \frac{mgr}{\frac{1}{2}MR^2 + mr^2}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{(25\,\text{kg})(9.81\,\text{m/s}^2)(0.65\,\text{m})}{\frac{1}{2}(60\,\text{kg})(0.45\,\text{m})^2 + (25\,\text{kg})(0.65\,\text{m})^2} = \boxed{9.6\,\text{rad/s}^2}$$

(*b*) Use conservation of mechanical energy to relate the initial potential energy of the load to its kinetic energy and the rotational kinetic energy of the wheel when the load is directly below the center of mass of the wheel:

$$\Delta K + \Delta U = 0$$

or, because $K_{\text{i}} = U_{\text{f}} = 0$,

$$K_{\text{f,trans}} + K_{\text{f,rot}} - U_{\text{i}} = 0\,.$$

Substitute for $K_{\text{f,trans}}$, $K_{\text{f,rot}}$, and U_{i} to obtain:

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\omega^2 - mgr = 0$$

Solving for ω yields:

$$\omega = \sqrt{\frac{4mgr}{2mr^2 + MR^2}}$$

Substitute numerical values and evaluate ω:

$$\omega=\sqrt{\frac{4(25\,\text{kg})(9.81\,\text{m/s}^2)(0.65\,\text{m})}{2(25\,\text{kg})(0.65\,\text{m})^2+(60\,\text{kg})(0.45\,\text{m})^2}}=\boxed{4.4\,\text{rad/s}}$$

117 •• A uniform disk of radius R and mass M is pivoted about a horizontal axis parallel to its symmetry axis and passing through a point on its perimeter, so that it can swing freely in a vertical plane (Figure 9-72). It is released from rest with its center of mass at the same height as the pivot. (*a*) What is the angular speed of the disk when its center of mass is directly below the pivot? (*b*) What force is exerted by the pivot on the disk at this moment?

Picture the Problem Let the zero of gravitational potential energy be at the center of the disk when it is directly below the pivot. The initial gravitational potential energy of the disk is transformed into rotational kinetic energy when its center of mass is directly below the pivot. We can use Newton's second law to relate the force exerted by the pivot to the weight of the disk and the centripetal force acting on it at its lowest point.

(*a*) Use conservation of mechanical energy to relate the initial potential energy of the disk to its kinetic energy when its center of mass is directly below the pivot:

$$\Delta K+\Delta U=0$$

or, because $K_i = U_f = 0$,

$$K_{\text{f,rot}}-U_i=0$$

Substitute for $K_{\text{f,rot}}$ and U_i to obtain:

$$\tfrac{1}{2}I\omega^2-Mgr=0 \qquad (1)$$

Use the parallel-axis theorem to relate the moment of inertia of the disk about the pivot to its moment of inertia with respect to an axis through its center of mass:

$$I=I_{\text{cm}}+Mh^2$$

or

$$I=\tfrac{1}{2}Mr^2+Mr^2=\tfrac{3}{2}Mr^2$$

Substituting for I in equation (1) yields:

$$\tfrac{1}{2}\left(\tfrac{3}{2}Mr^2\right)\omega^2-Mgr=0\Rightarrow\omega=\boxed{\sqrt{\frac{4g}{3r}}}$$

(*b*) Letting F represent the force exerted by the pivot, use Newton's second law to express the net force acting on the swinging disk as it passes through its lowest point:

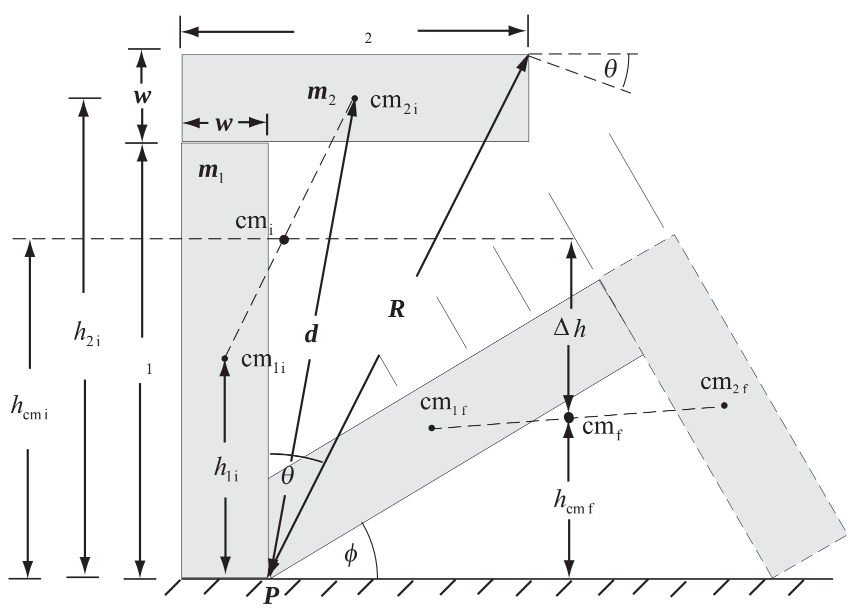
$$F_{\text{net}}=F-Mg=Mr\omega^2$$

Solve for F to obtain: $F = Mg + Mr\omega^2$

Substituting for ω^2 and simplifying yields: $F = Mg + Mr\dfrac{4g}{3r} = \boxed{\tfrac{7}{3}Mg}$

118 •• The roof of the student dining hall at your college will be supported by high cross-braced wooden beams attached in the shape of an upside-down *L* (Figure 9-73). Each vertical member is 10.0 ft high and 2.0 ft wide, and the horizontal cross-member is 8.0 ft long. The mass of the vertical beam is 350 kg, and the mass of the horizontal beam is 280 kg. As the workers were building the hall, one of these structures started to fall over before it was anchored into place. (Luckily, they stopped it before it fell.) (*a*) If it started falling from an upright position, what was the initial angular acceleration of the structure? Assume that the bottom did not slide across the floor and that it did not fall ″out of plane,″ that is, that during the fall the structure remained in the vertical plane defined by the initial position of the structure. (*b*) What would be the magnitude of the initial linear acceleration of the upper right corner of the horizontal beam? (*c*) What would the horizontal component of the initial linear acceleration be at this same location? (*d*) Estimate the structure's rotational speed at impact.

Picture the Problem The following pictorial representation shows one of the structures initially in its upright position and, later, as it is about to strike the floor. Because we need to take moments about the axis of rotation (a line through point *P*), we'll need to use the parallel-axis theorem to find the moments of inertia of the two parts of this composite structure. Let the numeral 1 denote the vertical member and the numeral 2 the horizontal member. We can apply Newton's second law in rotational form to the structure to express its angular acceleration in terms of the net torque causing it to fall and its moment of inertia with respect to point *P*.



(*a*) Taking clockwise rotation to be positive (this is the direction the structure is going to rotate), apply $\sum \tau = I_P \alpha$:

$$m_2 g\left(\tfrac{1}{2}\ell_2 - w\right) - m_1 g\left(\tfrac{1}{2}w\right) = I_P \alpha$$

Solving for α and substituting $I_{1P} + I_{2P}$ for I_P gives:

$$\alpha = \frac{\left[m_2\left(\tfrac{1}{2}\ell_2 - w\right) - \tfrac{1}{2}m_1 w\right]g}{I_{1P} + I_{2P}} \quad (1)$$

Using Table 9-1 and the parallel-axis theorem, express the moment of inertia of the vertical member about an axis through point *P*:

$$I_{1P} = \tfrac{1}{12}m_1\left(\ell_1^2 + w^2\right) + m_1\left[\left(\tfrac{1}{2}\ell_1\right)^2 + \left(\tfrac{1}{2}w\right)^2\right]$$
$$= \tfrac{1}{3}m_1\left(\ell_1^2 + w^2\right)$$

Substitute numerical values and evaluate I_{1P}:

$$I_{1P} = \tfrac{1}{3}(350\,\text{kg})\left[(10.0\,\text{ft})^2 + (2.0\,\text{ft})^2\right]\left(0.3048\frac{\text{m}}{\text{ft}}\right)^2 = 1.127\times10^3\,\text{kg}\cdot\text{m}^2$$

Using the parallel-axis theorem, express the moment of inertia of the horizontal member about an axis through point *P*:

$$I_{2P} = I_{2,\text{cm}} + m_2 d^2 \quad (2)$$

where

$$d^2 = \left(\ell_1 + \tfrac{1}{2}w\right)^2 + \left(\tfrac{1}{2}\ell_2 - w\right)^2$$

From Table 9-1 we have:

$$I_{2\,\text{cm}} = \tfrac{1}{12}m_2\left(\ell_2^2 + w^2\right)$$

Substitute for $I_{2\,\text{cm}}$ and d^2 in equation (2) and simplify to obtain:

$$I_{2P} = m_2\left[\tfrac{1}{3}\ell_2^2 + \tfrac{4}{3}w^2 + \ell_1^2 + \left(\ell_1 - \ell_2\right)w\right]$$

Substitute numerical values and evaluate I_{2P}:

$$I_{2P} = (280\,\text{kg})\left[\tfrac{1}{3}(8.0\,\text{ft})^2 + \tfrac{4}{3}(2.0\,\text{ft})^2 + (10.0\,\text{ft})^2 + (10.0\,\text{ft} - 8.0\,\text{ft})(2.0\,\text{ft})\right]$$
$$\times\left(0.3048\frac{\text{m}}{\text{ft}}\right)^2$$
$$= 3.399\times10^3\,\text{kg}\cdot\text{m}^2$$

Substitute numerical values in equation (1) and evaluate α:

$$\alpha = \frac{\left[(280\,\text{kg})\left[\tfrac{1}{2}(8.0\text{ ft}) - 2(2.0\text{ ft})\right] - \tfrac{1}{2}(350\,\text{kg})(2.0\text{ ft})\right]\left(9.81\,\text{m/s}^2\right)\left(0.3048\,\frac{\text{m}}{\text{ft}}\right)}{1.127\times10^3\ \text{kg}\cdot\text{m}^2 + 3.399\times10^3\ \text{kg}\cdot\text{m}^2}$$

$$= 0.1387\,\text{rad/s}^2 = \boxed{0.14\,\text{rad/s}^2}$$

(b) Express the magnitude of the acceleration of the top right-corner of the cross member:

$$a = \alpha R$$

Because $R = \sqrt{(\ell_1 + w)^2 + (\ell_2 - w)^2}$:

$$a = \alpha\sqrt{(\ell_1 + w)^2 + (\ell_2 - w)^2}$$

Substitute numerical values and evaluate a:

$$a = \left(0.1387\text{ rad/s}^2\right)\sqrt{(10.0\text{ ft} + 2.0\text{ ft})^2 + (8.0\text{ ft} - 2.0\text{ ft})^2}\left(0.3048\,\frac{\text{m}}{\text{ft}}\right)$$

$$= 0.5672\text{ m/s}^2 = \boxed{57\text{ cm/s}^2}$$

(c) a_x is given by:

$$a_x = a\cos\theta$$

Substitute for $\cos\theta$ (see the diagram) to obtain:

$$a_x = a\left(\frac{\ell_1 + w}{R}\right) = a\left(\frac{\ell_1 + w}{\sqrt{(\ell_1 + w)^2 + (\ell_2 - w)^2}}\right)$$

Substitute numerical values and evaluate a_x:

$$a_x = \left(0.5672\,\text{m/s}^2\right)\left(\frac{10.0\,\text{ft} + 2.0\text{ ft}}{\sqrt{(10.0\text{ ft} + 2.0\text{ ft})^2 + (8.0\text{ ft} - 2.0\text{ ft})^2}}\right) = 0.5073\,\text{m/s}^2$$

$$= \boxed{51\,\text{cm/s}^2}$$

(d) Letting the system include the beam and Earth, apply conservation of mechanical energy to the beam to obtain:

$$\Delta K + \Delta U_{\text{g}} = K_{\text{f}} - K_{\text{i}} + U_{\text{f}} - U_{\text{i}} = 0$$

where the subscript "f" refers to the instant just before it is caught and the subscript "i" refers to the instant just after it starts to move.

Let $U_g = 0$ at the location of the center of mass of the composite beam when it is about to hit the floor. Then:

$$K_f - U_i = 0$$

Substituting for K_f and U_i yields:

$$\tfrac{1}{2} I_P \omega_f^2 - (m_1 + m_2) g |\Delta h| = 0$$

where $\Delta h = h_{cm\,f} - h_{cm\,i}$ is the change in height of the center of mass of the composite beam.

Solving for ω_f gives:

$$\omega_f = \sqrt{\frac{2(m_1 + m_2) g |\Delta h|}{I_P}} = \sqrt{\frac{2(m_1 + m_2) g |\Delta h|}{I_{1P} + I_{2P}}} \qquad (3)$$

$h_{cm\,i}$ is given by:

$$h_{cm\,i} = \frac{\frac{1}{2}\ell_1 m_1 + \left(\ell_1 + \frac{1}{2}w\right) m_2}{m_1 + m_2}$$

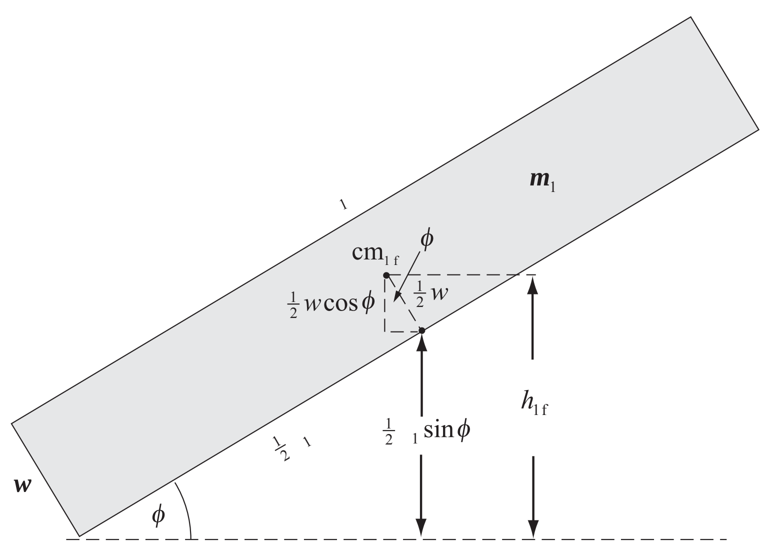
Substitute numerical values and evaluate $h_{cm\,i}$:

$$h_{cm\,i} = \frac{\left[\frac{1}{2}(10.0\text{ ft})(350\text{ kg}) + \left[10.0\text{ ft} + \frac{1}{2}(2.0\text{ ft})\right](280\text{ kg})\right]}{350\text{ kg} + 280\text{ kg}} = 7.667\text{ ft}$$

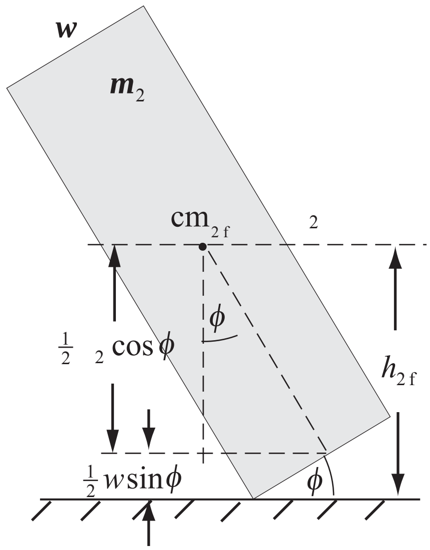
$h_{cm\,f}$ is given by:

$$h_{cm\,f} = \frac{h_{1f} m_1 + h_{2f} m_2}{m_1 + m_2}$$

Use the following diagram to show that $h_{1f} = \frac{1}{2}\ell_1 \sin\phi + \frac{1}{2} w \cos\phi$:



Use the following diagram to show that $h_{2\,\mathrm{f}} = \frac{1}{2}w\sin\phi + \frac{1}{2}\ell_2\cos\phi$.



Substituting for $h_{1\,\mathrm{f}}$ and $h_{2\,\mathrm{f}}$ gives:

$$h_{\mathrm{cm\,f}} = \frac{\left(\frac{1}{2}\ell_1\sin\phi + \frac{1}{2}w\cos\phi\right)m_1 + \left(\frac{1}{2}w\sin\phi + \frac{1}{2}\ell_2\cos\phi\right)m_2}{m_1 + m_2}$$

Noting that $\phi = \tan^{-1}\left(\dfrac{6.0\text{ ft}}{10.0\text{ ft}}\right) = 30.96°$, substitute numerical values and evaluate $h_{\mathrm{cm\,f}}$:

$$\begin{aligned} h_{\mathrm{cm\,f}} &= \frac{\left[\frac{1}{2}(10.0\text{ ft})\sin 30.96° + \frac{1}{2}(2.0\text{ ft})\cos 30.96°\right](350\text{ kg})}{350\text{ kg} + 280\text{ kg}} \\ &\quad + \frac{\left[\frac{1}{2}(2.0\text{ ft})\sin 30.96° + \frac{1}{2}(8.0\text{ ft})\cos 30.96°\right](280\text{ kg})}{350\text{ kg} + 280\text{ kg}} \\ &= 3.658\text{ ft} \end{aligned}$$

Substitute numerical values and evaluate $|\Delta h| = |h_{\mathrm{cm\,f}} - h_{\mathrm{cm\,i}}|$:

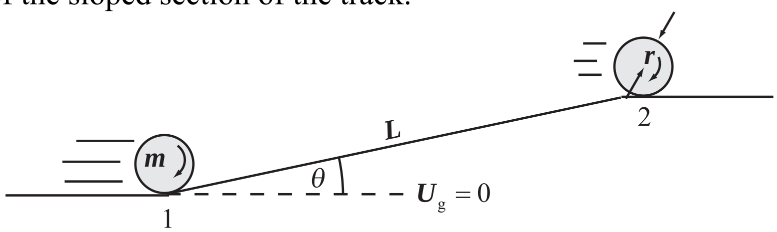
$$\begin{aligned} |\Delta h| &= |3.658\text{ ft} - 7.667\text{ ft}| = 4.009\text{ ft} \\ &= (4.009\text{ ft})\left(0.3048\frac{\text{m}}{\text{ft}}\right) = 1.222\text{ m} \end{aligned}$$

Substitute numerical values in equation (3) and evaluate ω_f:

$$\omega_\mathrm{f} = \sqrt{\frac{2(350\text{ kg} + 280\text{ kg})(9.81\text{ m/s}^2)(1.222\text{ m})}{1.127\times10^3\text{ kg}\cdot\text{m}^2 + 3.399\times10^3\text{ kg}\cdot\text{m}^2}} \approx \boxed{1.83\text{ rad/s}}$$

119 •• **[SSM]** You are participating in league bowling with your friends. Time after time, you notice that your bowling ball rolls back to you without slipping on the flat section of track. When the ball encounters the slope that brings it up to the ball return, it is moving at 3.70 m/s. The length of the sloped part of the track is 2.50 m. The radius of the bowling ball is 11.5 cm. (*a*) What is the angular speed of the ball before it encounters the slope? (*b*) If the speed with which the ball emerges at the top of the incline is 0.40 m/s, what is the angle (assumed constant), that the sloped section of the track makes with the horizontal? (*c*) What is the magnitude of the angular acceleration of the ball while it is on the slope?

Picture the Problem The pictorial representation shows the bowling ball slowing down as it rolls up the slope. Let the system include the ball, the incline, and Earth. Then $W_{ext} = 0$ and we can use conservation of mechanical energy to find the angle of the sloped section of the track.



(*a*) Because the bowling ball rolls without slipping, its angular speed is directly proportional to its linear speed:

$$\omega = \frac{v}{r}$$

where r is the radius of the bowling ball.

Substitute numerical values and evaluate ω:

$$\omega = \frac{3.70\ \text{m/s}}{0.115\ \text{m}} = 32.17\ \text{rad/s} = \boxed{32.2\ \text{rad/s}}$$

(*b*) Apply conservation of mechanical energy to the system as the bowling ball rolls up the incline:

$$W_{ext} = \Delta K + \Delta U$$

or, because $W_{ext} = 0$,

$$K_{t,2} - K_{t,1} + K_{r,2} - K_{r,1} + U_2 - U_1 = 0$$

Substituting for the kinetic and potential energies yields:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 + \tfrac{1}{2}I_{ball}\omega_2^2 - \tfrac{1}{2}I_{ball}\omega_1^2 + mgL\sin\theta = 0$$

Solving for θ yields:

$$\theta = \sin^{-1}\left[\frac{m\left(v_1^2 - v_2^2\right) + I_{ball}\left(\omega_1^2 - \omega_2^2\right)}{2mgL}\right]$$

Because $I_{\text{ball}} = \frac{2}{5}mr^2$:

$$\theta = \sin^{-1}\left[\frac{m\left(v_1^2 - v_2^2\right) + \frac{2}{5}mr^2\left(\omega_1^2 - \omega_2^2\right)}{2mgL}\right]$$
$$= \sin^{-1}\left[\frac{7\left(v_1^2 - v_2^2\right)}{10gL}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{7\left((3.70\text{ m/s})^2 - (0.40\text{ m/s})^2\right)}{10\left(9.81\text{ m/s}^2\right)(2.50\text{ m})}\right]$$
$$= \boxed{23°}$$

(*c*) The angular acceleration of the bowling ball is directly proportional to its translational acceleration:

$$\alpha = \frac{a}{r} \qquad (1)$$

Use a constant-acceleration equation to relate the speeds of the ball at points 1 and 2 to its acceleration:

$$v_2^2 = v_1^2 + 2aL \Rightarrow a = \frac{v_2^2 - v_1^2}{2L}$$

Substitute in equation (1) to obtain:

$$\alpha = \frac{v_2^2 - v_1^2}{2rL}$$

Substitute numerical values and evaluate $|\alpha|$:

$$|\alpha| = \left|\frac{(0.40\text{ m/s})^2 - (3.70\text{ m/s})^2}{2(0.115\text{ m})(2.50\text{ m})}\right|$$
$$= \boxed{24\text{ rad/s}^2}$$

120 •• Figure 9-74 shows a hollow cylinder that has a length equal to 1.80 m, a mass equal to 0.80 kg, and radius equal to 0.20 m. The cylinder is free to rotate about a vertical axis that passes through its center and is perpendicular to the cylinder. Two objects are inside the cylinder. Each object has a mass equal to 0.20 kg, and is attached to a spring that has a force constant *k* and has an unstressed length equal to 0.40 m. The inside walls of the cylinder are frictionless. (*a*) Determine the value of the force constant if the objects are located 0.80 m from the center of the cylinder when the cylinder rotates at 24 rad/s. (*b*) How much work is required to bring the system from rest to an angular speed of 24 rad/s?

Picture the Problem Let *m* represent the mass of the 0.20-kg objects, *M* the mass of the 0.80-kg hollow cylinder, *L* the 1.8-m length, and $x + \Delta x$ the distance from the center of the objects whose mass is *m*. We can use Newton's second law to relate the radial forces on the masses to the spring's force constant and use the work-energy theorem to find the work done as the system accelerates to its final angular speed.

(*a*) Express the net inward force acting on each of the 0.2-kg masses:

$$\sum F_{\text{radial}} = k\Delta x = m(x + \Delta x)\omega^2$$

Solving for *k* yields:

$$k = \frac{m(x + \Delta x)\omega^2}{\Delta x}$$

Substitute numerical values and evaluate *k*:

$$k = \frac{(0.20\,\text{kg})(0.80\,\text{m})(24\,\text{rad/s})^2}{0.40\,\text{m}} = 230\,\text{N/m} = \boxed{0.23\,\text{kN/m}}$$

(*b*) Using the work-energy theorem, relate the work done to the change in energy of the system:

$$W = K_{\text{rot}} + \Delta U_{\text{spring}} = \tfrac{1}{2}I\omega^2 + \tfrac{1}{2}k(\Delta x)^2 \qquad (1)$$

From Table 9-1 we have, for a cylindrical shell about a diameter through its center:

$$I = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2$$

where L is the length of the cylinder.

Express I as the sum of the moments of inertia of the cylindrical shell and the masses:

$$I = I_M + I_{2m} = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2I_m$$

For a disk (thin cylinder), L is small and:

$$I = \tfrac{1}{4}mr^2$$

Apply the parallel-axis theorem to obtain:

$$I_m = \tfrac{1}{4}mr^2 + mx^2$$

Substitute to obtain:

$$I = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2\left(\tfrac{1}{4}mr^2 + mx^2\right) = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2m\left(\tfrac{1}{4}r^2 + x^2\right)$$

Substitute numerical values and evaluate I:

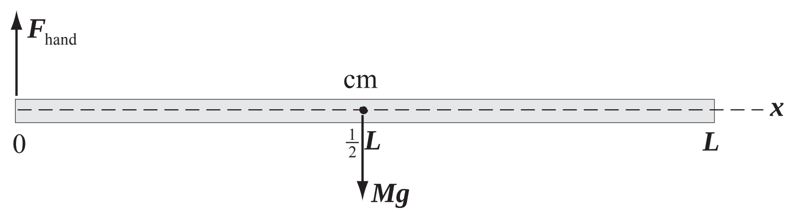
$$I = \tfrac{1}{2}(0.80\,\text{kg})(0.20\,\text{m})^2 + \tfrac{1}{12}(0.80\,\text{kg})(1.8\,\text{m})^2 + 2(0.20\,\text{kg})\left[\tfrac{1}{4}(0.20\,\text{m})^2 + (0.80\,\text{m})^2\right] = 0.492\,\text{N}\cdot\text{m}^2$$

Substitute in equation (1) to obtain:

$$W = \tfrac{1}{2}(0.492\,\text{N}\cdot\text{m}^2)(24\,\text{rad/s})^2 + \tfrac{1}{2}(230\,\text{N/m})(0.40\,\text{m})^2 = \boxed{0.16\,\text{kJ}}$$

121 •• **[SSM]** A popular classroom demonstration involves taking a meterstick and holding it horizontally at the 0.0-cm end with a number of pennies spaced evenly along its surface. If the hand is suddenly relaxed so that the meterstick pivots freely about the 0.0-cm mark under the influence of gravity, an interesting thing is seen during the first part of the stick's rotation: the pennies nearest the 0.0-cm mark remain on the meterstick, while those nearest the 100-cm mark are left behind by the falling meterstick. (This demonstration is often called the ″faster than gravity″ demonstration.) Suppose this demonstration is repeated without any pennies on the meterstick. (*a*) What would the initial acceleration of the 100.0-cm mark then be? (The initial acceleration is the acceleration just after the release.) (*b*) What point on the meterstick would then have an initial acceleration greater than *g*?

Picture the Problem The diagram shows the force the hand supporting the meterstick exerts at the pivot point and the force Earth exerts on the meterstick acting at the center of mass. We can relate the angular acceleration to the acceleration of the end of the meterstick using $a = L\alpha$ and use Newton's second law in rotational form to relate α to the moment of inertia of the meterstick.



(*a*) Relate the acceleration of the far end of the meterstick to the angular acceleration of the meterstick:

$$a = L\alpha \qquad (1)$$

Apply $\sum \tau_P = I_P\alpha$ to the meterstick:

$$Mg\left(\frac{L}{2}\right) = I_P\alpha \Rightarrow \alpha = \frac{MgL}{2I_P}$$

From Table 9-1, for a rod pivoted at one end, we have:

$$I_P = \frac{1}{3}ML^2$$

Substitute for I_P in the expression for α to obtain:

$$\alpha = \frac{3MgL}{2ML^2} = \frac{3g}{2L}$$

Substitute for α in equation (1) to obtain:

$$a = \frac{3g}{2}$$

Substitute numerical values and evaluate *a*:

$$a = \frac{3\left(9.81\,\text{m/s}^2\right)}{2} = \boxed{14.7\,\text{m/s}^2}$$

(*b*) Express the acceleration of a point on the meterstick a distance x from the pivot point:

$$a = \alpha x = \frac{3g}{2L}x$$

Express the condition that the meterstick have an initial acceleration greater than g:

$$\frac{3g}{2L}x > g \Rightarrow x > \frac{2L}{3}$$

Substitute the numerical value of L and evaluate x:

$$x > \frac{2(100.0\,\text{cm})}{3} = \boxed{66.7\,\text{cm}}$$

122 •• A solid metal rod, 1.5 m long, is free to pivot without friction about a fixed horizontal axis perpendicular to the rod and passing through one of its ends. The rod is held in a horizontal position. Small coins, each of mass *m,* are placed on the rod 25 cm, 50 cm, 75 cm, 1 m, 1.25 m, and 1.5 m from the pivot. If the free end is now released, calculate the initial force exerted on each coin by the rod. Assume that the masses of the coins can be neglected in comparison to the mass of the rod.

Picture the Problem While the angular acceleration of the rod is the same at each point along its length, the linear acceleration and, hence, the force exerted on each coin by the rod, varies along its length. We can relate this force the linear acceleration of the rod through Newton's second law and the angular acceleration of the rod.

Letting x be the distance from the pivot, use Newton's second law to express the force F acting on a coin:

$$F_{\text{net}} = mg - F(x) = ma(x)$$

or

$$F(x) = m(g - a(x)) \qquad (1)$$

Use Newton's second law to relate the angular acceleration of the system to the net torque acting on it:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{Mg\frac{L}{2}}{\frac{1}{3}ML^2} = \frac{3g}{2L}$$

Relate $a(x)$ and α:

$$a(x) = x\alpha = x\frac{3g}{2(1.5\,\text{m})} = gx$$

Substitute in equation (1) to obtain:

$$F(x) = m(g - gx) = mg(1 - x)$$

Evaluate $F(0.25\text{ m})$:

$$F(0.25\,\text{m}) = mg(1 - 0.25\,\text{m}) = \boxed{0.75mg}$$

Evaluate $F(0.50\text{ m})$:

$$F(0.50\,\text{m}) = mg(1 - 0.50\,\text{m}) = \boxed{0.50mg}$$

Evaluate $F(0.75\text{ m})$:

$$F(0.75\,\text{m}) = mg(1 - 0.75\,\text{m}) = \boxed{0.25mg}$$

Evaluate $F(1.0\text{ m})$:

$$F(1.0\,\text{m}) = F(1.25\,\text{m}) = F(1.5\,\text{m}) = \boxed{0}$$

123 •• Suppose that for the system described in Problem 120, the force constants are each 60 N/m. The system starts from rest and slowly accelerates until the masses are 0.80 m from the center of the cylinder. How much work was done in the process?

Picture the Problem Let m represent the mass of the 0.20-kg cylinder, M the mass of the 0.80-kg cylinder, L the 1.80-m length, and $x + \Delta x$ the distance from the center of the objects whose mass is m. We can use Newton's second law to relate the radial forces on the masses to the spring's force constant and use the work-energy theorem to find the work done as the system accelerates to its final angular speed.

Using the work-energy theorem, relate the work done to the change in energy of the system:

$$W = K_{\text{rot}} + \Delta U_{\text{spring}} = \tfrac{1}{2}I\omega^2 + \tfrac{1}{2}k(\Delta x)^2 \qquad (1)$$

From Table 9-1 we have, for a cylindrical shell about a diameter through its center:

$$I = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2$$

where L is the length of the cylinder.

Express I as the sum of the moments of inertia of the cylinder and the masses:

$$I = I_M + I_{2m} = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2I_m$$

For a disk (thin cylinder), L is small and:

$$I = \tfrac{1}{4}mr^2$$

Apply the parallel-axis theorem to obtain:

$$I_m = \tfrac{1}{4}mr^2 + mx^2$$

Substitute for the moments of inertia and simplify to obtain:

$$I = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2\left(\tfrac{1}{4}mr^2 + mx^2\right) = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2m\left(\tfrac{1}{4}r^2 + x^2\right)$$

Substitute numerical values and evaluate I:

$$I = \tfrac{1}{2}(0.80\,\text{kg})(0.20\,\text{m})^2 + \tfrac{1}{12}(0.80\,\text{kg})(1.80\,\text{m})^2 + 2(0.20\,\text{kg})\left[\tfrac{1}{4}(0.20\,\text{m})^2 + (0.80\,\text{m})^2\right]$$
$$= 0.492\,\text{N}\cdot\text{m}^2$$

Express the net inward force acting on each of the 0.2-kg masses:

$$\sum F_{\text{radial}} = k\Delta x = m(x+\Delta x)\omega^2$$

Solving for ω yields:

$$\omega = \sqrt{\frac{k\Delta x}{m(x+\Delta x)}}$$

Substitute numerical values and evaluate ω:

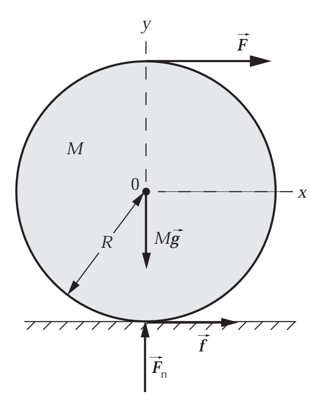
$$\omega = \sqrt{\frac{(60\,\text{N/m})(0.40\,\text{m})}{(0.20\,\text{kg})(0.80\,\text{m})}} = 12.25\,\text{rad/s}$$

Substitute numerical values in equation (1) and evaluate W:

$$W = \tfrac{1}{2}(0.492\,\text{N}\cdot\text{m}^2)(12.25\,\text{rad/s})^2 + \tfrac{1}{2}(60\,\text{N/m})(0.40\,\text{m})^2 = \boxed{42\,\text{J}}$$

124 ••• A string is wrapped around a uniform solid cylinder of radius R and mass M that rests on a horizontal frictionless surface (The string does not touch the surface because there is a groove cut in the surface to provide space for the string to clear). The string is pulled horizontally from the top with force F. (*a*) Show that the magnitude of the angular acceleration of the cylinder is twice the magnitude of the angular acceleration needed for rolling without slipping, so that the bottom point on the cylinder slides backward against the table. (*b*) Find the magnitude and direction of the frictional force between the table and cylinder that would be needed for the cylinder to roll without slipping. What would be the magnitude of the acceleration of the cylinder in this case?

Picture the Problem The force diagram shows the forces acting on the cylinder. Because F causes the cylinder to rotate clockwise, f, which opposes this motion, is to the right. We can use Newton's second law in both translational and rotational forms to relate the linear and angular accelerations to the forces acting on the cylinder.



(*a*) Use Newton's second law to relate the angular acceleration of the center of mass of the cylinder to *F*:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{FR}{\frac{1}{2}MR^2} = \frac{2F}{MR}$$

Use Newton's second law to relate the acceleration of the center of mass of the cylinder to *F*:

$$a_{\text{cm}} = \frac{F_{\text{net}}}{M} = \frac{F}{M}$$

Apply the rolling-without-slipping condition to the linear and angular accelerations:

$$\alpha' = \frac{a_{\text{cm}}}{R}$$

Substituting for a_{cm} yields:

$$\alpha' = \frac{F}{MR} = \boxed{\tfrac{1}{2}\alpha}$$

(*b*) Take the point of contact with the floor as the ″pivot″ point, express the net torque about that point:

$$\tau_{\text{net}} = 2FR = I\alpha \Rightarrow \alpha = \frac{2FR}{I} \qquad (1)$$

Express the moment of inertia of the cylinder with respect to the pivot point:

$$I = \tfrac{1}{2}MR^2 + MR^2 = \tfrac{3}{2}MR^2$$

Substitute for *I* in equation (1) to obtain:

$$\alpha = \frac{2FR}{\frac{3}{2}MR^2} = \frac{4F}{3MR}$$

The linear acceleration of the cylinder is:

$$a_{\text{cm}} = R\alpha = \boxed{\frac{4F}{3M}}$$

Apply Newton's second law to the cylinder to obtain:

$$\sum F_x = F + f = Ma_{\text{cm}}$$

Solving for *f* and substituting for a_{cm} yields:

$$f = Ma_{\text{cm}} - F = \frac{4F}{3} - F$$

$$= \boxed{\tfrac{1}{3}F \text{ in the } +x \text{ direction.}}$$

125 ••• **[SSM]** Let's calculate the position *y* of the falling load attached to the winch in Example 9-8 as a function of time by numerical integration. Let the +*y* direction be straight downward. Then, $v(y) = dy/dt$, or

$$t=\int_0^y \frac{1}{v(y')}dy' \approx \sum_{i=0}^{N} \frac{1}{v(y_i')}\Delta y'$$

where t is the time taken for the bucket to fall a distance y, $\Delta y'$ is a small increment of y', and $y' = N\Delta y'$. Hence, we can calculate t as a function of d by numerical summation. Make a graph of y versus t between 0 s and 2.00 s. Assume m_w = 10.0 kg, R = 0.50 m, m_b = 5.0 kg, L = 10.0 m, and m_c = 3.50 kg. Use $\Delta y'$ = 0.10 m. Compare this position to the position of the falling load if it were in free-fall.

Picture the Problem As the load falls, mechanical energy is conserved. As in Example 9-7, choose the initial potential energy to be zero and let the system include the winch, the bucket, and Earth. Apply conservation of mechanical energy to obtain an expression for the speed of the bucket as a function of its position and use the given expression for t to determine the time required for the bucket to travel a distance y.

Apply conservation of mechanical energy to the system to obtain:

$$U_f + K_f = U_i + K_i = 0 + 0 = 0 \qquad (1)$$

Express the total potential energy when the bucket has fallen a distance y:

$$U_f = U_{bf} + U_{cf} + U_{wf} = -mgy - m_c'g\left(\frac{y}{2}\right)$$

where m_c' is the mass of the hanging part of the cable.

Assume the cable is uniform and express m_c' in terms of m_c, y, and L:

$$\frac{m_c'}{y} = \frac{m_c}{L} \text{ or } m_c' = \frac{m_c}{L}y$$

Substitute for m_c' to obtain:

$$U_f = -mgy - \frac{m_c g y^2}{2L}$$

Noting that bucket, cable, and rim of the winch have the same speed v, express the total kinetic energy when the bucket is falling with speed v:

$$\begin{aligned} K_f &= K_{bf} + K_{cf} + K_{wf} \\ &= \tfrac{1}{2}mv^2 + \tfrac{1}{2}m_c v^2 + \tfrac{1}{2}I\omega_f^2 \\ &= \tfrac{1}{2}mv^2 + \tfrac{1}{2}m_c v^2 + \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\frac{v^2}{R^2} \\ &= \tfrac{1}{2}mv^2 + \tfrac{1}{2}m_c v^2 + \tfrac{1}{4}Mv^2 \end{aligned}$$

Substituting in equation (1) yields:

$$-mgy - \frac{m_c g y^2}{2L} + \tfrac{1}{2}mv^2 + \tfrac{1}{2}m_c v^2 + \tfrac{1}{4}Mv^2 = 0$$

Solving for v yields:

$$v = \sqrt{\frac{4mgy + \frac{2m_c gy^2}{L}}{M + 2m + 2m_c}}$$

A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
D9	0	y_0
D10	D9+$B$8	$y + \Delta y$
E9	0	v_0
E10	((4*$B$3*$B$7*D10+2*$B$7*D10^2/(2*$B$5))/ ($B$1+2*$B$3+2*$B$4))^0.5	$\sqrt{\frac{4mgy + \frac{2m_c gy^2}{L}}{M + 2m + 2m_c}}$
F10	F9+$B$8/((E10+E9)/2)	$t_{n-1} + \left(\frac{v_{n-1} + v_n}{2}\right)\Delta y$

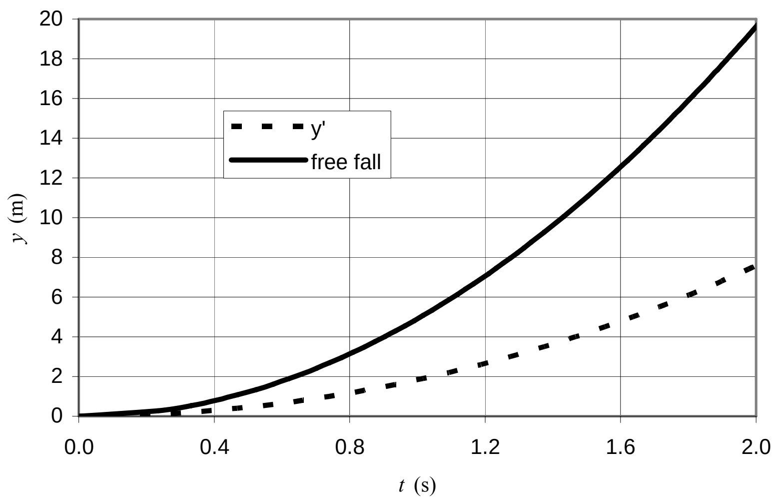
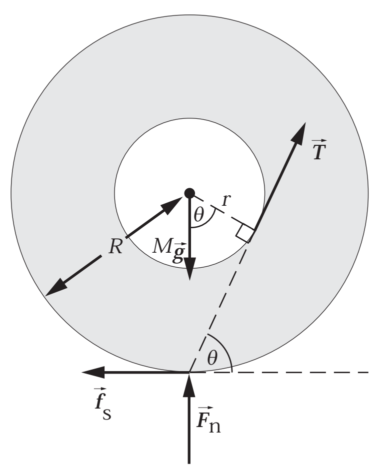
The solid line on the following graph shows the position of the bucket as a function of time when it is in free fall and the dashed line shows its position as a function of time under the conditions modeled in this problem.



126 ••• Figure 9-75 shows a solid cylinder that has mass M and radius R to which a second solid cylinder that has mass m and radius r is attached. A string is wound about the smaller cylinder. The larger cylinder rests on a horizontal surface. The coefficient of static friction between the larger cylinder and the surface is μ_s. If a light tension is applied to the string in the vertical direction, the cylinder will roll to the left; if the tension is applied with the string horizontally to the right, the cylinder rolls to the right. Find the angle between the string and the horizontal that will allow the cylinder to remain stationary when a light tension is applied to the string.

Picture the Problem The pictorial representation shows the forces acting on the cylinder when it is stationary. First, we note that if the tension is small, then there can be no slipping, and the system must roll. Now consider the point of contact of the cylinder with the surface as the "pivot" point. If τ about that point is zero, the system will not roll. This will occur if the line of action of the tension passes through the pivot point.

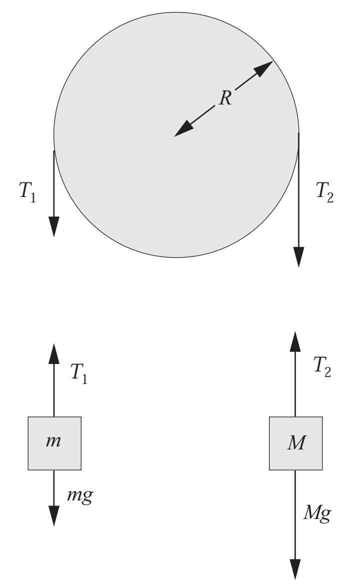


From the diagram we see that:

$$\theta = \boxed{\cos^{-1}\left(\frac{r}{R}\right)}$$

127 ••• [SSM] In problems dealing with a pulley with a nonzero moment of inertia, the magnitude of the tensions in the ropes hanging on either side of the pulley are not equal. The difference in the tension is due to the static frictional force between the rope and the pulley; however, the static frictional force cannot be made arbitrarily large. Consider a massless rope wrapped partly around a cylinder through an angle $\Delta\theta$ (measured in radians). It can be shown that if the tension on one side of the pulley is T, while the tension on the other side is T' ($T' > T$), the maximum value of T' that can be maintained without the rope slipping is $T'_{\text{max}} = Te^{\mu_s \Delta\theta}$, where μ_s is the coefficient of static friction. Consider the Atwood's machine in Figure 9-77: the pulley has a radius $R = 0.15$ m, the moment of inertia is $I = 0.35\ \text{kg}\cdot\text{m}^2$, and the coefficient of static friction between the wheel and the string is $\mu_s = 0.30$. (*a*) If the tension on one side of the pulley is 10 N, what is the maximum tension on the other side that will prevent the rope from slipping on the pulley? (*b*) What is the acceleration of the blocks in this case? (*c*) If the mass of one of the hanging blocks is 1.0 kg, what is the maximum mass of the other block if, after the blocks are released, the pulley is to rotate without slipping?

Picture the Problem Free-body diagrams for the pulley and the two blocks are shown to the right. Choose a coordinate system in which the direction of motion of the block whose mass is M (downward) is the $+y$ direction. We can use the given relationship $T'_{\text{max}} = Te^{\mu_s \Delta\theta}$ to relate the tensions in the rope on either side of the pulley and apply Newton's second law in both rotational form (to the pulley) and translational form (to the blocks) to obtain a system of equations that we can solve simultaneously for a, T_1, T_2, and M.



(*a*) Use $T'_{\text{max}} = Te^{\mu_s \Delta\theta}$ to evaluate the maximum tension required to prevent the rope from slipping on the pulley:

$$T'_{\text{max}} = (10\ \text{N})e^{(0.30)\pi} = 25.66\ \text{N} = \boxed{26\ \text{N}}$$

(*b*) Given that the angle of wrap is π radians, express T_2 in terms of T_1:

$$T_2 = T_1 e^{(0.30)\pi} \qquad (1)$$

Because the rope doesn't slip, we can relate the angular acceleration, α, of the pulley to the acceleration, a, of the hanging masses by:

$$\alpha = \frac{a}{R}$$

Apply $\sum \tau = I\alpha$ to the pulley to obtain:

$$(T_2 - T_1)R = I\frac{a}{R} \qquad (2)$$

Substitute for T_2 from equation (1) in equation (2) to obtain:

$$\left(T_1 e^{(0.30)\pi} - T_1\right)R = I\frac{a}{R}$$

Solving for T_1 yields:

$$T_1 = \frac{I}{\left(e^{(0.30)\pi} - 1\right)R^2}a$$

Apply $\sum F_y = ma_y$ to the block whose mass is m to obtain:

$$T_1 - mg = ma$$

and

$$T_1 = ma + mg \qquad (3)$$

Equating these two expressions for T_1 and solving for a yields:

$$a = \frac{g}{\dfrac{I}{\left(e^{(0.30)\pi} - 1\right)mR^2} - 1}$$

Substitute numerical values and evaluate a:

$$a = \frac{9.81\,\text{m/s}^2}{\dfrac{0.35\,\text{kg}\cdot\text{m}^2}{\left(e^{(0.30)\pi} - 1\right)(1.0\,\text{kg})(0.15\,\text{m})^2} - 1}$$

$$= 1.098\,\text{m/s}^2 = \boxed{1.1\,\text{m/s}^2}$$

(*c*) Apply $\sum F_y = ma_y$ to the block whose mass is M to obtain:

$$Mg - T_2 = Ma \Rightarrow M = \frac{T_2}{g - a}$$

Substitute for T_2 (from equation (1)) and T1 (from equation (3)) yields:

$$M = \frac{m(a + g)e^{(0.30)\pi}}{g - a}$$

Substitute numerical values and evaluate M:

$$M = \frac{(1.0\,\text{kg})\left(1.098\,\text{m/s}^2 + 9.81\,\text{m/s}^2\right)e^{(0.30)\pi}}{9.81\,\text{m/s}^2 - 1.098\,\text{m/s}^2} = \boxed{3.2\,\text{kg}}$$

128 ••• A massive, uniform cylinder has a mass m and a radius R (Figure 9-77). It is accelerated by a tension force $\vec{T}$ that is applied through a rope wound around a light drum of radius r that is attached to the cylinder. The coefficient of static friction is sufficient for the cylinder to roll without slipping. (*a*) Find the frictional force. (*b*) Find the acceleration a of the center of the cylinder. (*c*) Show that it is possible to choose r so that a is greater than T/m. (*d*) What is the direction of the frictional force in the circumstances of Part (*c*)?

Picture the Problem When the tension is horizontal, the cylinder will roll forward and the friction force will be in the direction of $\vec{T}$. We can use Newton's second law to obtain equations that we can solve simultaneously for a and f.

(*a*) Apply Newton's second law to the cylinder:

$$\sum F_x = T + f = ma \qquad (1)$$

and

$$\sum \tau = Tr - fR = I\alpha \qquad (2)$$

Substitute for I and α in equation (2) to obtain:

$$Tr - fR = \tfrac{1}{2}mR^2\frac{a}{R} = \tfrac{1}{2}mRa \qquad (3)$$

Solve equation (3) for f:

$$f = \frac{Tr}{R} - \tfrac{1}{2}ma \qquad (4)$$

Substitute equation (4) in equation (1) to obtain:

$$T + \frac{Tr}{R} - \tfrac{1}{2}ma = ma$$

Solving for a gives:

$$a = \frac{2T}{3m}\left(1 + \frac{r}{R}\right) \qquad (5)$$

Substitute equation (5) in equation (4) to obtain:

$$f = \frac{Tr}{R} - \frac{1}{2}m\left[\frac{2T}{3m}\left(1 + \frac{r}{R}\right)\right]$$

Simplifying yields:

$$f = \boxed{\frac{T}{3}\left(\frac{2r}{R} - 1\right)}$$

(*b*) Solve equation (4) for a:

$$a = \frac{2\left(f - \frac{Tr}{R}\right)}{m}$$

Substituting for f yields:

$$a = \frac{2\left(\frac{T}{3}\left(\frac{2r}{R} - 1\right) - \frac{Tr}{R}\right)}{m}$$

$$= \boxed{-\frac{2T}{3m}\left(1 + \frac{r}{R}\right)}$$

(c) Express the condition that $a > \frac{T}{m}$:

$$\frac{2T}{3m}\left(1+\frac{r}{R}\right) > \frac{T}{m} \Rightarrow \frac{2}{3}\left(1+\frac{r}{R}\right) > 1$$

or

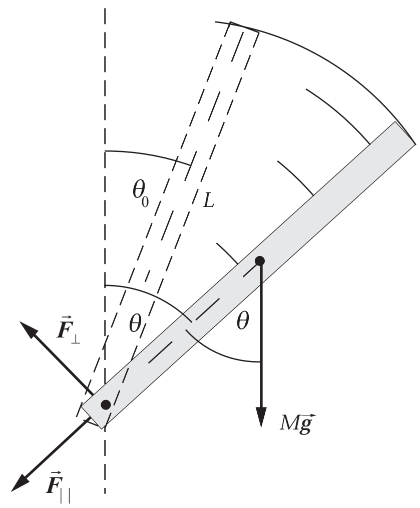
$$r > \boxed{\tfrac{1}{2}R}$$

(d) If $r > \frac{1}{2}R$:

$$\boxed{f > 0, \text{i.e., in the direction of } \vec{\boldsymbol{T}}.}$$

129 ••• A uniform rod that has a length L and a mass M is free to rotate about a horizontal axis through one end, as shown in Figure 9-78. The rod is released from rest at $\theta = \theta_0$. Show that the parallel and perpendicular components of the force exerted by the axis on the rod are given by $F_{\|} = \frac{1}{2}Mg(5\cos\theta - 3\cos\theta_0)$ and $F_{\perp} = \frac{1}{4}Mg\sin\theta$, where $F_{\|}$ is the component parallel with the rod and $F_{\perp}$ is the component perpendicular to the rod.

Picture the Problem The system is shown in the drawing in two positions, with angles θ_0 and θ with the vertical. The drawing also shows all the forces that act on the rod. These forces result in a rotation of the rod—and its center of mass—about the pivot, and a tangential acceleration of the center of mass. We'll apply the conservation of mechanical energy and Newton's second law to relate the radial and tangential forces acting on the stick.



Apply conservation of mechanical energy to relate the kinetic energy of the stick when it makes an angle θ with the vertical to its initial potential energy:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_i = 0$,

$$K_f + U_f - U_i = 0$$

Substituting for K_f, U_f and U_i gives:

$$\tfrac{1}{2}I\omega^2 + Mg\frac{L}{2}\cos\theta - Mg\frac{L}{2}\cos\theta_0 = 0$$

Substitute for I to obtain:

$$\tfrac{1}{2}\left(\tfrac{1}{3}ML^2\right)\omega^2 + Mg\frac{L}{2}\cos\theta - Mg\frac{L}{2}\cos\theta_0 = 0$$

Solving for ω^2 yields:

$$\omega^2 = \frac{3g}{L}\left(\cos\theta_0 - \cos\theta\right)$$

Applying Newton's second law in the centripetal direction gives:

$$F_{\parallel} + F_{\text{g c}} = M\frac{L}{2}\omega^2$$

where toward the pivot is the positive centripetal direction.

Substituting for the gravitational force component yields:

$$F_{\parallel} + Mg\cos\theta = M\frac{L}{2}\omega^2$$

or, solving for $F_{\parallel}$,

$$F_{\parallel} = M\frac{L}{2}\omega^2 - Mg\cos\theta$$

Substitute for ω^2 and simplify to obtain:

$$\begin{aligned} F_{\parallel} &= M\frac{L}{2}\left[\frac{3g}{L}\left(\cos\theta_0 - \cos\theta\right)\right] - Mg\cos\theta \\ &= \tfrac{1}{2}Mg\left[\left(3\cos\theta_0 - 3\cos\theta\right)\right] - Mg\cos\theta \\ &= \tfrac{1}{2}Mg\left[\left(3\cos\theta_0 - 3\cos\theta - 2\cos\theta\right)\right] \\ &= \boxed{-\tfrac{1}{2}Mg\left[\left(5\cos\theta - 3\cos\theta_0\right)\right]} \end{aligned}$$

where the minus sign is a consequence of our choice of the positive direction for the centripetal force.

Relate the tangential acceleration of the center of mass to its angular acceleration:

$$a_{\perp} = \tfrac{1}{2}L\alpha$$

Use Newton's second law to relate the angular acceleration of the stick to the net torque acting on it:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{Mg\frac{L}{2}\sin\theta}{\frac{1}{3}ML^2} = \frac{3g\sin\theta}{2L}$$

Express $a_{\perp}$ in terms of α:⊥

$$a_{\perp} = \tfrac{1}{2}L\alpha = \tfrac{3}{4}g\sin\theta = g\sin\theta + \frac{F_{\perp}}{M}$$

Solving for $F_{\perp}$ yields:

$F_{\perp} = \boxed{-\tfrac{1}{4}Mg\sin\theta}$ where the minus sign indicates that the force is directed oppositely to the tangential component of $M\vec{g}$.

Chapter 10
Angular Momentum

Conceptual Problems

1 • True or false:

(*a*) If two vectors are exactly opposite in direction, their vector product must be zero.
(*b*) The magnitude of the vector product of two vectors is at a minimum when the two vectors are perpendicular.
(*c*) Knowing the magnitude of the vector product of two nonzero vectors and the vectors′ individual magnitudes uniquely determines the angle between them.

Determine the Concept The vector product of $\vec{A}$ and $\vec{B}$ is defined to be $\vec{A}\times\vec{B} = AB\sin\phi\,\hat{n}$ where $\hat{n}$ is a unit vector normal to the plane defined by $\vec{A}$ and $\vec{B}$ and ϕ is the angle between $\vec{A}$ and $\vec{B}$.

(*a*) True. If $\vec{A}$ and $\vec{B}$ are in opposite direction, then $\sin\phi = \sin 180° = 0$.

(*b*) False. If $\vec{A}$ and $\vec{B}$ are perpendicular, then $\sin\phi = \sin 90° = 1$ and the vector product of $\vec{A}$ and $\vec{B}$ is a maximum.

(*c*) False. Knowing the magnitude of the vector product and the vectors′ individual magnitudes only gives the magnitude of the sine of the angle between the vectors. It does not determine the angle uniquely, nor does this knowledge tell us if the sine of the angle is positive or negative.

2 • Consider two nonzero vectors $\vec{A}$ and $\vec{B}$. Their vector product has the greatest magnitude if $\vec{A}$ and $\vec{B}$ are (*a*) parallel, (*b*) perpendicular, (*c*) antiparallel, (*d*) at an angle of 45° to each other.

Determine the Concept The vector product of the vectors $\vec{A}$ and $\vec{B}$ is defined to be $\vec{A}\times\vec{B} = AB\sin\phi\,\hat{n}$ where $\hat{n}$ is a unit vector normal to the plane defined by $\vec{A}$ and $\vec{B}$ and ϕ is the angle between $\vec{A}$ and $\vec{B}$. Hence, the vector product of $\vec{A}$ and $\vec{B}$ is a maximum when $\sin\phi = 1$. This condition is satisfied provided $\vec{A}$ and $\vec{B}$ are *perpendicular*. $\boxed{(b)}$ is correct.

3 • What is the angle between a force vector $\vec{F}$ and a torque vector $\vec{\tau}$ produced by $\vec{F}$?

Determine the Concept Because $\vec{\tau} = \vec{r} \times \vec{F} = rF\sin\phi\,\hat{n}$, where $\hat{n}$ is a unit vector normal to the plane defined by $\vec{r}$ and $\vec{F}$, the angle between $\vec{F}$ and $\vec{\tau}$ is $\boxed{90°.}$

4 • A point particle of mass *m* is moving with a constant speed *v* along a straight line that passes through point *P*. What can you say about the angular momentum of the particle relative to point *P*? (*a*) Its magnitude is *mv*. (*b*) Its magnitude is zero. (*c*) Its magnitude changes sign as the particle passes through point *P*. (*d*) It varies in magnitude as the particle approaches point *P*.

Determine the Concept $\vec{L}$ and $\vec{p}$ are related according to $\vec{L} = \vec{r} \times \vec{p}$ and the magnitude of $\vec{L}$ is $L = rp\sin\phi$ where ϕ is the angle between $\vec{r}$ and $\vec{p}$. Because the motion is along a line that passes through point *P*, $r = 0$ and so is *L*. $\boxed{(b)}$ is correct.

5 • **[SSM]** A particle travels in a circular path and point *P* is at the center of the circle. (*a*) If the particle's linear momentum $\vec{p}$ is doubled without changing the radius of the circle, how is the magnitude of its angular momentum about *P* affected? (*b*) If the radius of the circle is doubled but the speed of the particle is unchanged, how is the magnitude of its angular momentum about *P* affected?

Determine the Concept $\vec{L}$ and $\vec{p}$ are related according to $\vec{L} = \vec{r} \times \vec{p}$ and the magnitude of $\vec{L}$ is $L = rp\sin\phi$ where ϕ is the angle between $\vec{r}$ and $\vec{p}$.

(*a*) Because $\vec{L}$ is directly proportional to $\vec{p}$, *L* is doubled.

(*b*) Because $\vec{L}$ is directly proportional to $\vec{r}$, *L* is doubled.

6 • A particle moves along a straight line at constant speed. How does its angular momentum about any fixed point vary with time?

Determine the Concept We can determine how the angular momentum of the particle about any fixed point varies with time by examining the derivative of the cross product of $\vec{r}$ and $\vec{p}$.

The angular momentum of the particle is given by: $\vec{L} = \vec{r} \times \vec{p}$

Differentiate $\vec{L}$ with respect to time to obtain:

$$\frac{d\vec{L}}{dt} = \left(\vec{r} \times \frac{d\vec{p}}{dt}\right) + \left(\frac{d\vec{r}}{dt} \times \vec{p}\right) \qquad (1)$$

Because $\vec{p} = m\vec{v}$, $\frac{d\vec{p}}{dt} = \vec{F}_{\text{net}}$, and $\frac{d\vec{r}}{dt} = \vec{v}$:

$$\frac{d\vec{L}}{dt} = \left(\vec{r} \times \vec{F}_{\text{net}}\right) + \left(\vec{v} \times \vec{p}\right)$$

Because the particle moves along a straight line at constant speed:

$$F_{\text{net}} = 0 \Rightarrow \vec{r} \times \vec{F}_{\text{net}} = 0$$

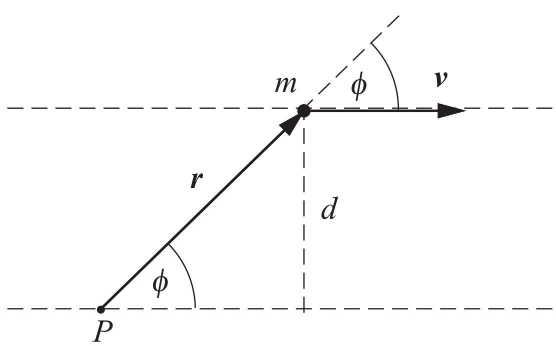
Because $\vec{v}$ and $\vec{p}(= m\vec{v})$ are parallel:

$$\vec{v} \times \vec{p} = 0$$

Substitute in equation (1) to obtain:

$$\frac{d\vec{L}}{dt} = 0 \Rightarrow \vec{L} = \boxed{\text{constant}}$$

<u>**An alternate solution**</u> The following diagram shows a particle whose mass is *m* moving along a straight line at constant speed. The point identified as *P* is any fixed point and the vector $\vec{r}$ is the position vector, relative to this fixed point, of the particle moving with constant velocity.



From the definition of angular momentum, the magnitude of the angular momentum of the particle, relative to the fixed point at *P,* is given by:

$$\left|\vec{L}\right| = rmv\sin\phi = mv(r\sin\phi)$$

Because $d = r\sin\phi$:

$$\left|\vec{L}\right| = mvd$$

or, because *m, v* and *d* are constants,

$$\left|\vec{L}\right| = \boxed{\text{constant}}$$

7 •• True or false: If the net torque on a rotating system is zero, the angular velocity of the system cannot change. If your answer is false, give an example of such a situation.

False. The net torque acting on a rotating system equals the change in the system's angular momentum; that is, $\tau_{\text{net}} = dL/dt$ where $L = I\omega$. Hence, if τ_{net} is zero, all we can say for sure is that the angular momentum (the product of I and ω) is constant. If I changes, so must ω. An example is a high diver going from a tucked to a layout position.

8 •• You are standing on the edge of a turntable with frictionless bearings that is initially rotating when you catch a ball that is moving in the same direction but faster than you are moving and on a line tangent to the edge of the turntable. Assume you do not move relative to the turntable. (*a*) Does the angular speed of the turntable increase, decrease, or remain the same during the catch? (*b*) Does the magnitude of your angular momentum (about the rotation axis of the table) increase, decrease, or remain the same after the catch? (*c*) How does the ball's angular momentum (about the rotation axis of the table) change after the catch? (*d*) How does the total angular momentum of the system, you-table-ball (about the rotation axis of the table) change after the catch?

Determine the Concept You can apply conservation of angular momentum to the you-table-ball system to answer each of these questions.

(*a*) Because the ball is moving in the same direction that you are moving, your angular speed will $\boxed{\text{increase}}$ when you catch it. Your Newton's 3rd law interaction with the ball causes a torque that acts on the you-table-ball system to increase ω.

(*b*) The ball has angular momentum relative to the rotation axis of the table before you catch it and so catching it $\boxed{\text{increases}}$ your angular momentum relative to the rotation axis of the table.

(*c*) The ball will slow down as a result of your catch and so its angular momentum relative to the center of the table will $\boxed{\text{decrease.}}$

(*d*) Because there is zero net torque on the you-table-ball system, its angular momentum $\boxed{\text{remains the same.}}$

9 •• If the angular momentum of a system about a fixed point P is constant, which one of the following statements must be true?

(*a*) No torque about P acts on any part of the system.
(*b*) A constant torque about P acts on each part of the system.
(*c*) Zero net torque about P acts on each part of the system.
(*d*) A constant external torque about P acts on the system.
(*e*) Zero net external torque about P acts on the system.

Determine the Concept If L is constant, we know that the *net* torque acting on the system is zero. There may be multiple constant or time-dependent torques acting on the system as long as the net torque is zero. $\boxed{(e)}$ is correct.

10 •• A block sliding on a frictionless table is attached to a string that passes through a narrow hole through the tabletop. Initially, the block is sliding with speed v_0 in a circle of radius r_0. A student under the table pulls slowly on the string. What happens as the block spirals inward? Give supporting arguments for your choice. (The term angular momentum refers to the angular momentum about a vertical axis through the hole.) (*a*) Its energy and angular momentum are conserved. (*b*) Its angular momentum is conserved and its energy increases. (*c*) Its angular momentum is conserved and its energy decreases. (*d*) Its energy is conserved and its angular momentum increases. (*e*) Its energy is conserved and its angular momentum decreases.

Determine the Concept The pull that the student exerts on the block is at right angles to its motion and exerts no torque (recall that $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{r}} \times \vec{\boldsymbol{F}}$ and $\tau = rF\sin\phi$). Therefore, we can conclude that the angular momentum of the block is conserved. The student does, however, do work in displacing the block in the direction of the radial force and so the block's energy increases. $\boxed{(b)}$ is correct.

11 •• **[SSM]** One way to tell if an egg is hardboiled or uncooked without breaking the egg is to lay the egg flat on a hard surface and try to spin it. A hardboiled egg will spin easily, while an uncooked egg will not. However, once spinning, the uncooked egg will do something unusual; if you stop it with your finger, it may start spinning again. Explain the difference in the behavior of the two types of eggs.

Determine the Concept The hardboiled egg is solid inside, so everything rotates with a uniform angular speed. By contrast, when you start an uncooked egg spinning, the yolk will not immediately spin with the shell, and when you stop it from spinning the yolk will continue to spin for a while.

12 •• Explain why a helicopter with just one main rotor has a second smaller rotor mounted on a horizontal axis at the rear as in Figure 10-40. Describe the resultant motion of the helicopter if this rear rotor fails during flight.

Determine the Concept The purpose of the second smaller rotor is to prevent the body of the helicopter from rotating. If the rear rotor fails, the body of the helicopter will tend to rotate on the main axis due to angular momentum being conserved.

13 •• The spin angular-momentum vector for a spinning wheel is parallel with its axle and is pointed east. To cause this vector to rotate toward the south, in which direction must a force be exerted on the east end of the axle? (*a*) up, (*b*) down, (*c*) north, (*d*) south, (*e*) east.

Determine the Concept The vector $\Delta\vec{L} = \vec{L}_f - \vec{L}_i$ (and the torque that is responsible for this change in the direction of the angular momentum vector) initially points to the south. One can use a right-hand rule to determine the direction of this torque, and hence the force exerted on the east end of the axle, required to cause the angular-momentum vector to rotate toward the south. Letting the fingers of your right hand point east, rotate your wrist until your thumb points south. Note that your curled fingers, which point in the direction of the force that must be exerted on the east end of the axle, point upward. $\boxed{(a)}$ is correct.

14 •• You are walking toward the north and in your left hand you are carrying a suitcase that contains a massive spinning wheel mounted on an axle attached to the front and back of the case. The angular velocity of the gyroscope points north. You now begin to turn to walk toward the east. As a result, the front end of the suitcase will (*a*) resist your attempt to turn it and will try to maintain its original orientation, (*b*) resist your attempt to turn and will pull to the west, (*c*) rise upward, (*d*) dip downward, (*e*) show no effect whatsoever.

Determine the Concept In turning toward the east, you redirect the angular momentum vector from north to east by exerting a torque on the spinning wheel. The force that you must exert to produce this torque (use a right-hand rule with your thumb pointing either east of north and note that your fingers point upward) is upward. That is, the force you exert on the front end of the suitcase is upward and the force the suitcase exerts on you is downward. Consequently, the front end of the suitcase will dip downward. $\boxed{(d)}$ is correct.

15 •• [SSM] The angular momentum of the propeller of a small single-engine airplane points forward. The propeller rotates clockwise if viewed from behind. (*a*) Just after liftoff, as the nose of the plane tilts upward, the airplane tends to veer to one side. To which side does it tend to veer and why? (*b*) If the plane is flying horizontally and suddenly turns to the right, does the nose of the plane tend to veer upward or downward? Why?

(*a*) The plane tends to veer to the right. The change in angular momentum $\Delta\vec{L}_{\text{prop}}$ for the propeller is upward, so the net torque $\vec{\tau}$ on the propeller is upward as well. The propeller must exert an equal but opposite torque on the plane. This downward torque exerted on the plane by the propeller tends to cause a downward

change in the angular momentum of the plane. This means the plane tends to rotate clockwise as viewed from above.

(*b*) The nose of the plane tends to veer downward. The change in angular momentum $\Delta\vec{\boldsymbol{L}}_{\text{prop}}$ for the propeller is to the right, so the net torque $\vec{\boldsymbol{\tau}}$ on the propeller is toward the right as well. The propeller must exert an equal but opposite torque on the plane. This leftward directed torque exerted by the propeller on the plane tends to cause a leftward-directed change in angular momentum for the plane. This means the plane tends to rotate clockwise as viewed from the right.

16 •• You have designed a car that is powered by the energy stored in a single flywheel with a spin angular momentum $\vec{L}$. In the morning, you plug the car into an electrical outlet and a motor spins the flywheel up to speed, adding a huge amount of rotational kinetic energy to it—energy that will be changed into translational kinetic energy of the car during the day. Having taken a physics course involving angular momentum and torques, you realize that problems would arise during various maneuvers of the car. Discuss some of these problems. For example, suppose the flywheel is mounted so $\vec{\boldsymbol{L}}$ points vertically upward when the car is on a horizontal road. What would happen as the car travels over a hilltop? Through a valley? Suppose the flywheel is mounted so $\vec{\boldsymbol{L}}$ points forward, or to one side, when the car is on a horizontal road. Then what would happen as the car attempts to turn to the left or right? In each case that you examine, consider the direction of the torque exerted on the car by the road.

Determine the Concept If $\vec{\boldsymbol{L}}$ points upward and the car travels over a hill or through a valley, the force the road exerts on the wheels on one side (or the other) will increase and car will tend to tip. If $\vec{\boldsymbol{L}}$ points forward and the car turns left or right, the front (or rear) of the car will tend to lift. These problems can be averted by having two identical flywheels that rotate on the same shaft in opposite directions.

17 •• [SSM] You are sitting on a spinning piano stool with your arms folded. (*a*) When you extend your arms out to the side, what happens to your kinetic energy? What is the cause of this change? (*b*) Explain what happens to your moment of inertia, angular speed and angular momentum as you extend your arms.

Determine the Concept The rotational kinetic energy of the you-stool system is given by $K_{\text{rot}} = \frac{1}{2}I\omega^2 = \dfrac{L^2}{2I}$. Because the net torque acting on the you-stool system is zero, its angular momentum $\vec{\boldsymbol{L}}$ is conserved.

(*a*) Your kinetic energy decreases. Increasing your moment of inertia I while conserving your angular momentum L decreases you kinetic energy $K = \frac{L^2}{2I}$.

(*b*) Extending your arms out to the side increases your moment of inertia, decreases your angular speed. The angular momentum of the system is unchanged.

18 •• A uniform rod of mass M and length L rests on a horizontal frictionless table. A blob of putty of mass $m = M/4$ moves along a line perpendicular to the rod, strikes the rod near its end, and sticks to the rod. Describe qualitatively the subsequent motion of the rod and putty.

Determine the Concept The center of mass of the rod-and-putty system moves in a straight line, and the system rotates about its center of mass.

Estimation and Approximation

19 •• **[SSM]** An ice-skater starts her pirouette with arms outstretched, rotating at 1.5 rev/s. Estimate her rotational speed (in revolutions per second) when she brings her arms flat against her body.

Picture the Problem Because we have no information regarding the mass of the skater, we'll assume that her body mass (not including her arms) is 50 kg and that each arm has a mass of 4.0 kg. Let's also assume that her arms are 1.0 m long and that her body is cylindrical with a radius of 20 cm. Because the net external torque acting on her is zero, her angular momentum will remain constant during her pirouette.

Because the net external torque acting on her is zero:

$$\Delta L = L_\mathrm{f} - L_\mathrm{i} = 0$$

or

$$I_{\text{arms in}}\omega_{\text{arms in}} - I_{\text{arms out}}\omega_{\text{arms out}} = 0 \quad (1)$$

Express her total moment of inertia with her arms outstretched:

$$I_{\text{arms out}} = I_{\text{body}} + I_{\text{arms}}$$

Treating her body as though it is cylindrical, calculate the moment of inertia of her body, minus her arms:

$$I_{\text{body}} = \tfrac{1}{2}mr^2 = \tfrac{1}{2}(50\,\mathrm{kg})(0.20\,\mathrm{m})^2 = 1.00\,\mathrm{kg\cdot m^2}$$

Modeling her arms as though they are rods, calculate their moment of inertia when they are outstretched:

$$I_{\text{arms}} = 2\left[\tfrac{1}{3}(4\,\text{kg})(1.0\,\text{m})^2\right] = 2.67\,\text{kg}\cdot\text{m}^2$$

Substitute to determine her total moment of inertia with her arms outstretched:

$$I_{\text{arms out}} = 1.00\,\text{kg}\cdot\text{m}^2 + 2.67\,\text{kg}\cdot\text{m}^2 = 3.67\,\text{kg}\cdot\text{m}^2$$

Express her total moment of inertia with her arms flat against her body:

$$\begin{aligned} I_{\text{arms in}} &= I_{\text{body}} + I_{\text{arms}} \\ &= 1.00\,\text{kg}\cdot\text{m}^2 + 2\left[(4.0\,\text{kg})(0.20\,\text{m})^2\right] \\ &= 1.32\,\text{kg}\cdot\text{m}^2 \end{aligned}$$

Solve equation (1) for $\omega_{\text{arms in}}$ to obtain:

$$\omega_{\text{arms in}} = \frac{I_{\text{arms out}}}{I_{\text{arms in}}}\omega_{\text{arms out}}$$

Substitute numerical values and evaluate $\omega_{\text{arms in}}$:

$$\omega_{\text{arms in}} = \frac{3.67\,\text{kg}\cdot\text{m}^2}{1.32\,\text{kg}\cdot\text{m}^2}(1.5\,\text{rev/s}) \approx \boxed{4\,\text{rev/s}}$$

20 •• Estimate the ratio of angular velocities for the rotation of a diver between the full tuck position and the full-layout position.

Picture the Problem Because the net external torque acting on the diver is zero, the diver's angular momentum will remain constant as she rotates from the full tuck to the full layout position. Assume that, in layout position, the diver is a thin rod of length 2.5 m and that, in the full tuck position, the diver is a sphere of radius 0.50 m.

Because the net external torque acting on the diver is zero:

$$\Delta L = L_{\text{layout}} - L_{\text{tuck}} = 0$$

or

$$I_{\text{layout}}\omega_{\text{layout}} - I_{\text{tuck}}\omega_{\text{tuck}} = 0$$

Solving for the ratio of the angular velocities gives:

$$\frac{\omega_{\text{tuck}}}{\omega_{\text{layout}}} = \frac{I_{\text{layout}}}{I_{\text{tuck}}}$$

Substituting for the moment of inertia of a thin rod relative to an axis through its center of mass and the moment of inertia of a sphere relative to its center of mass and simplifying yields:

$$\frac{\omega_{\text{tuck}}}{\omega_{\text{layout}}}=\frac{\frac{1}{12}m\ell^2}{\frac{2}{5}mr^2}=\frac{5\ell^2}{24r^2}$$

Substitute numerical values and evaluate $\omega_{\text{tuck}}/\omega_{\text{layout}}$:

$$\frac{\omega_{\text{tuck}}}{\omega_{\text{layout}}}=\frac{5(2.5\text{ m})^2}{24(0.50\text{ m})^2}\approx\boxed{5}$$

21 •• The days on Mars and Earth are of nearly identical length. Earth's mass is 9.35 times Mars's mass, Earth's radius is 1.88 times Mars's radius, and Mars is on average 1.52 times farther away from the Sun than Earth is. The Martian year is 1.88 times longer than Earth's year. Assume that they are both uniform spheres and that their orbits about the Sun are circles. Estimate the ratio (Earth to Mars) of (*a*) their spin angular momenta, (*b*) their spin kinetic energies, (*c*) their orbital angular momenta, and (*d*) their orbital kinetic energies.

Picture the Problem We can use the definitions of spin angular momentum, spin kinetic energy, orbital angular momentum, and orbital kinetic energy to evaluate these ratios.

(*a*) The ratio of the spin angular momenta of Earth and Mars is:

$$\left(\frac{L_{\text{E}}}{L_{\text{M}}}\right)_{\text{spin}}=\frac{I_{\text{E}}\omega_{\text{E}}}{I_{\text{M}}\omega_{\text{M}}}$$

Because Mars and Earth have nearly identical lengths of days, $\omega_{\text{E}}\approx\omega_{\text{M}}$:

$$\left(\frac{L_{\text{E}}}{L_{\text{M}}}\right)_{\text{spin}}\approx\frac{I_{\text{E}}}{I_{\text{M}}}$$

Substituting for the moments of inertia and simplifying yields:

$$\left(\frac{L_{\text{E}}}{L_{\text{M}}}\right)_{\text{spin}}\approx\frac{\frac{2}{5}M_{\text{E}}R_{\text{E}}^2}{\frac{2}{5}M_{\text{M}}R_{\text{M}}^2}=\frac{M_{\text{E}}}{M_{\text{M}}}\left(\frac{R_{\text{E}}}{R_{\text{M}}}\right)^2$$

Substitute numerical values for the ratios and evaluate $\left(\frac{L_{\text{E}}}{L_{\text{M}}}\right)_{\text{spin}}$:

$$\left(\frac{L_{\text{E}}}{L_{\text{M}}}\right)_{\text{spin}}\approx 9.35(1.88)^2\approx\boxed{33}$$

(*b*) The ratio of the spin kinetic energies of Earth and Mars is:

$$\left(\frac{K_{\text{E}}}{K_{\text{M}}}\right)_{\text{spin}}=\frac{\dfrac{L_{\text{E}}^2}{2I_{\text{E}}}}{\dfrac{L_{\text{M}}^2}{2I_{\text{M}}}}=\frac{L_{\text{E}}^2}{L_{\text{M}}^2}\frac{I_{\text{M}}}{I_{\text{E}}}$$

Because $\left(\frac{L_E}{L_M}\right)_{spin} \approx \frac{I_E}{I_M}$:

$$\left(\frac{K_E}{K_M}\right)_{spin} = \frac{L_E^2}{L_M^2}\frac{L_M}{L_E} = \left(\frac{L_E}{L_M}\right)_{spin}$$

From (*a*) $\left(\frac{L_E}{L_M}\right)_{spin} \approx 33$. Hence:

$$\left(\frac{K_E}{K_M}\right)_{spin} \approx \boxed{33}$$

(*c*) Treating Earth and Mars as point objects, the ratio of their orbital angular momenta is:

$$\left(\frac{L_E}{L_M}\right)_{orb} = \frac{I_E \omega_{orb,\,E}}{I_M \omega_{orb,\,M}}$$

Substituting for the moments of inertia and orbital angular speeds yields:

$$\left(\frac{L_E}{L_M}\right)_{orb} = \frac{M_E r_E^2 \left(\frac{2\pi}{T_E}\right)}{M_M r_M^2 \left(\frac{2\pi}{T_M}\right)}$$

where r_E and r_M are the radii of the orbits of Earth and Mars, respectively.

Simplify to obtain:

$$\left(\frac{L_E}{L_M}\right)_{orb} = \left(\frac{M_E}{M_M}\right)\left(\frac{r_E}{r_M}\right)^2\left(\frac{T_M}{T_E}\right)$$

Substitute numerical values for the three ratios and evaluate $\left(\frac{L_E}{L_M}\right)_{orb}$:

$$\left(\frac{L_E}{L_M}\right)_{orb} = (9.35)\left(\frac{1}{1.52}\right)^2(1.88) \approx \boxed{8}$$

(*d*) The ratio of the orbital kinetic energies of Earth and Mars is:

$$\left(\frac{K_E}{K_M}\right)_{orb} = \frac{\frac{1}{2}I_E \omega_{orb,\,E}^2}{\frac{1}{2}I_M \omega_{orb,\,M}^2}$$

Substituting for the moments of inertia and angular speeds and simplifying gives:

$$\left(\frac{K_E}{K_M}\right)_{orb} = \frac{M_E r_E^2 \left(\frac{2\pi}{T_E}\right)^2}{M_M r_M^2 \left(\frac{2\pi}{T_M}\right)^2} = \left(\frac{M_E}{M_M}\right)\left(\frac{r_E}{r_M}\right)^2\left(\frac{T_M}{T_E}\right)^2$$

Substitute numerical values for the ratios and evaluate $\left(\frac{K_E}{K_M}\right)_{orb}$:

$$\left(\frac{K_E}{K_M}\right)_{orb} = (9.35)\left(\frac{1}{1.52}\right)^2(1.88)^2 \approx \boxed{14}$$

22 •• The polar ice caps contain about 2.3×10^{19} kg of ice. This mass contributes negligibly to the moment of inertia of Earth because it is located at the poles, close to the axis of rotation. Estimate the change in the length of the day that would be expected if the polar ice caps were to melt and the water were distributed uniformly over the surface of Earth.

Picture the Problem The change in the length of the day is the difference between its length when the ice caps have melted and the water has been distributed over the surface of Earth and the length of the day before the ice caps melt. Because the net torque acting on Earth during this process is zero, angular momentum is conserved and we can relate the angular speed (which are related to the length of the day) of Earth before and after the ice caps melt to the moments of inertia of the Earth-plus-spherical shell the ice caps melt.

Express the change in the length of a day as:

$$\Delta T = T_{\text{after}} - T_{\text{before}} \qquad (1)$$

Because the net torque acting on Earth during this process is zero, angular momentum is conserved:

$$\Delta L = L_{\text{after}} - L_{\text{before}} = 0$$

Substituting for L_{after} and L_{before} yields:

$$\left(I_{\text{sphere}} + I_{\text{shell}}\right)\omega_{\text{after}} - I_{\text{sphere}}\omega_{\text{before}} = 0$$

Because $\omega = 2\pi/T$:

$$\left(I_{\text{sphere}} + I_{\text{shell}}\right)\frac{2\pi}{T_{\text{after}}} - I_{\text{sphere}}\frac{2\pi}{T_{\text{before}}} = 0$$

or, simplifying,

$$\frac{I_{\text{sphere}} + I_{\text{shell}}}{T_{\text{after}}} - \frac{I_{\text{sphere}}}{T_{\text{before}}} = 0$$

Solve for T_{after} to obtain:

$$T_{\text{after}} = \left(1 + \frac{I_{\text{shell}}}{I_{\text{sphere}}}\right)T_{\text{before}}$$

Substituting for T_{after} in equation (1) and simplifying yields:

$$\Delta T = \left(1 + \frac{I_{\text{shell}}}{I_{\text{sphere}}}\right)T_{\text{before}} - T_{\text{before}}$$

$$= \frac{I_{\text{shell}}}{I_{\text{sphere}}}T_{\text{before}}$$

Substitute for I_{shell} and I_{sphere} and simplify to obtain:

$$\Delta T = \frac{\frac{2}{3}mr^2}{\frac{2}{5}M_E R_E^2} T_{\text{before}} = \frac{5m}{3M_E} T_{\text{before}}$$

Substitute numerical values and evaluate ΔT:

$$\Delta T = \frac{5(2.3\times10^{19}\ \text{kg})}{3(5.98\times10^{24}\ \text{kg})}\left(1\,\text{d}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\,\text{s}}{\text{h}}\right) = \boxed{0.55\,\text{s}}$$

23 •• [SSM] A 2.0-g particle moves at a constant speed of 3.0 mm/s around a circle of radius 4.0 mm. (*a*) Find the magnitude of the angular momentum of the particle. (*b*) If $L = \sqrt{\ell(\ell+1)}\hbar$, where ℓ is an integer, find the value of $\ell(\ell+1)$ and the approximate value of ℓ. (*c*) By how much does ℓ change if the particle's speed increases by one-millionth of a percent, and nothing else changing? Use your result to explain why the quantization of angular momentum is not noticed in macroscopic physics.

Picture the Problem We can use $L = mvr$ to find the angular momentum of the particle. In (*b*) we can solve $L = \sqrt{\ell(\ell+1)}\hbar$ for $\ell(\ell+1)$ and the approximate value of ℓ.

(*a*) Use the definition of angular momentum to obtain:

$$L = mvr = (2.0\times10^{-3}\ \text{kg})(3.0\times10^{-3}\ \text{m/s})(4.0\times10^{-3}\ \text{m}) = 2.40\times10^{-8}\ \text{kg}\cdot\text{m}^2/\text{s}$$
$$= \boxed{2.4\times10^{-8}\ \text{kg}\cdot\text{m}^2/\text{s}}$$

(*b*) Solve the equation $L = \sqrt{\ell(\ell+1)}\hbar$ for $\ell(\ell+1)$:

$$\ell(\ell+1) = \frac{L^2}{\hbar^2} \qquad (1)$$

Substitute numerical values and evaluate $\ell(\ell+1)$:

$$\ell(\ell+1) = \left(\frac{2.40\times10^{-8}\ \text{kg}\cdot\text{m}^2/\text{s}}{1.05\times10^{-34}\ \text{J}\cdot\text{s}}\right)^2 = \boxed{5.2\times10^{52}}$$

Because $\ell >> 1$, approximate its value with the square root of $\ell(\ell+1)$:

$$\ell \approx \boxed{2.3\times10^{26}}$$

(*c*) The change in ℓ is:

$$\Delta\ell = \ell_{\text{new}} - \ell \qquad (2)$$

If the particle's speed increases by one-millionth of a percent while nothing else changes:

$$v \to v + 10^{-8} v = \left(1 + 10^{-8}\right)v$$
and
$$L \to L + 10^{-8} L = \left(1 + 10^{-8}\right)L$$

Equation (1) becomes:

$$\ell_{\text{new}}\left(\ell_{\text{new}} + 1\right) = \frac{\left[\left(1 + 10^{-8}\right)L\right]^2}{\hbar^2}$$
and
$$\ell_{\text{new}} \approx \frac{\left(1 + 10^{-8}\right)L}{\hbar}$$

Substituting in equation (2) yields:

$$\Delta\ell = \ell_{\text{new}} - \ell \approx \frac{\left(1 + 10^{-8}\right)L}{\hbar} - \frac{L}{\hbar} = 10^{-8}\frac{L}{\hbar}$$

Substitute numerical values and evaluate $\Delta\ell$:

$$\Delta\ell = 10^{-8}\left(\frac{2.40 \times 10^{-8}\ \text{kg}\cdot\text{m}^2/\text{s}}{1.05 \times 01^{-34}\ \text{J}\cdot\text{s}}\right)$$
$$= \boxed{2.3 \times 10^{18}}$$
and
$$\frac{\Delta\ell}{\ell} = \frac{2.3 \times 10^{18}}{2.3 \times 10^{26}} \approx 10^{-6}\%$$

The quantization of angular momentum is not noticed in macroscopic physics because no experiment can detect a fractional change in ℓ of $10^{-6}\%$.

24 ••• Astrophysicists in the 1960s tried to explain the existence and structure of *pulsars*—extremely regular astronomical sources of radio pulses whose periods ranged from seconds to milliseconds. At one point, these radio sources were given the acronym LGM (Little Green Men), a reference to the idea that they might be signals of extraterrestrial civilizations. The explanation given today is no less interesting. Consider the following. Our Sun, which is a fairly typical star, has a mass of 1.99×10^{30} kg and a radius of 6.96×10^{8} m. Although it does not rotate uniformly, because it is not a solid body, its average rate of rotation is about 1 rev/25 d. Stars larger than the Sun can end their life in spectacular explosions called supernovae, leaving behind a collapsed remnant of the star called a *neutron star*. These neutron-stars have masses comparable to the original masses of the stars but radii of only a few kilometers! The high rotation rates are due to the conservation of angular momentum during the collapses. These stars emit beams of radio waves. Because of the rapid angular speed of the stars, the beam sweeps past Earth at regular, very short, intervals. To produce the observed radio-wave pulses, the star has to rotate at rates that range from about 1 rev/s to 1000 rev/s. (*a*) Using data from the textbook, estimate the rotation rate of the Sun if it were to collapse into a neutron star of radius 10 km. The Sun is not a uniform sphere of

gas, and its moment of inertia is given by $I = 0.059MR^2$. Assume that the neutron star is spherical and has a uniform mass distribution. (*b*) Is the rotational kinetic energy of the Sun greater or smaller after the collapse? By what factor does it change, and where does the energy go to or come from?

Picture the Problem We can use conservation of angular momentum in Part (*a*) to relate the before-and-after collapse rotation rates of the Sun. In Part (*b*), we can express the fractional change in the rotational kinetic energy of the Sun as it collapses into a neutron star to decide whether its rotational kinetic energy is greater initially or after the collapse.

(*a*) Use conservation of angular momentum to relate the angular momenta of the Sun before and after its collapse:

$$I_b\omega_b = I_a\omega_a \Rightarrow \omega_a = \frac{I_b}{I_a}\omega_b \qquad (1)$$

Using the given formula, approximate the moment of inertia I_b of the Sun before collapse:

$$I_b = 0.059MR_{sun}^2 = 0.059(1.99\times10^{30}\text{ kg})(6.96\times10^5\text{ km})^2 = 5.69\times10^{46}\text{ kg}\cdot\text{m}^2$$

Find the moment of inertia I_a of the Sun when it has collapsed into a spherical neutron star of radius 10 km and uniform mass distribution:

$$\begin{aligned} I_a &= \tfrac{2}{5}MR^2 \\ &= \tfrac{2}{5}(1.99\times10^{30}\text{ kg})(10\text{ km})^2 \\ &= 7.96\times10^{37}\text{ kg}\cdot\text{m}^2 \end{aligned}$$

Substitute numerical values in equation (1) and simplify to obtain:

$$\begin{aligned} \omega_a &= \frac{5.69\times10^{46}\text{ kg}\cdot\text{m}^2}{7.96\times10^{37}\text{ kg}\cdot\text{m}^2}\omega_b \\ &= 7.15\times10^8\,\omega_b \end{aligned}$$

Given that ω_b = 1 rev/25 d, evaluate ω_a:

$$\begin{aligned} \omega_a &= 7.15\times10^8\left(\frac{1\text{rev}}{25\text{d}}\right) = 2.86\text{ rev/d} \\ &= \boxed{2.9\times10^7\text{ rev/d}} \end{aligned}$$

Note that the rotational period decreases by the same factor of I_b/I_a and becomes:

$$T_a = \frac{2\pi}{\omega_a} = \frac{2\pi}{2.86\times10^7\,\frac{\text{rev}}{\text{d}}\times\frac{2\pi\text{ rad}}{\text{rev}}\times\frac{1\text{d}}{24\text{h}}\times\frac{1\text{h}}{3600\text{s}}} = 3.0\times10^{-3}\text{ s}$$

(*b*) Express the fractional change in the Sun's rotational kinetic energy as a consequence of its collapse:

$$\frac{\Delta K}{K_b}=\frac{K_a-K_b}{K_b}=\frac{K_a}{K_b}-1$$

Substituting for the kinetic energies and simplifying yields:

$$\frac{\Delta K}{K_b}=\frac{\frac{1}{2}I_a\omega_a^2}{\frac{1}{2}I_b\omega_b^2}-1=\frac{I_a\omega_a^2}{I_b\omega_b^2}-1$$

Substitute numerical values and evaluate $\Delta K/K_b$:

$$\frac{\Delta K}{K_b}=\left(\frac{1}{7.15\times10^8}\right)\left(\frac{2.86\times10^7\text{ rev/d}}{1\text{rev/25d}}\right)^2-1=\boxed{7.1\times10^8}$$

That is, the rotational kinetic energy *increases* by a factor of approximately 7×10^8. The additional rotational kinetic energy comes at the expense of gravitational potential energy, which decreases as the Sun gets smaller.

25 •• The moment of inertia of Earth about its spin axis is approximately 8.03×10^{37} kg·m^2. (*a*) Because Earth is nearly spherical, assume that the moment of inertia can be written as $I = CMR^2$, where C is a dimensionless constant, $M = 5.98\times10^{24}$ kg is the mass of Earth, and $R = 6370$ km is its radius. Determine C. (*b*) If Earth's mass were distributed uniformly, C would equal 2/5. From the value of C calculated in Part (*a*), is Earth's density greater near its center or near its surface? Explain your reasoning.

Picture the Problem We can solve $I=CMR^2$ for C and substitute numerical values in order to determine an experimental value of C for Earth. We can then compare this value to those for a spherical shell and a sphere in which the mass is uniformly distributed to decide whether Earth's mass density is greatest near its core or near its crust.

(*a*) Express the moment of inertia of Earth in terms of the constant C:

$$I=CMR^2\Rightarrow C=\frac{I}{MR^2}$$

Substitute numerical values and evaluate C:

$$C=\frac{8.03\times10^{37}\text{ kg}\cdot\text{m}^2}{(5.98\times10^{24}\text{ kg})(6370\text{ km})^2}=\boxed{0.331}$$

(*b*) Because experimentally $C < 0.4$, the mass density must be greater near the center of Earth.

26 ••• Estimate Timothy Goebel's initial takeoff speed, rotational velocity, and angular momentum when he performs a quadruple Lutz (Figure 10-41). Make any assumptions you think reasonable, but justify them. Goebel's mass is about 60 kg and the height of the jump is about 0.60 m. Note that his angular speed will

change quite a bit during the jump, as he begins with arms outstretched and pulls them in. Your answer should be accurate to within a factor of 2, if you're careful.

Picture the Problem We'll assume that he launches himself at an angle of 45° with the horizontal with his arms spread wide, and then pulls them in to increase his rotational speed during the jump. We'll also assume that we can model him as a 2.0-m long cylinder with an average radius of 0.15 m and a mass of 60 kg. We can then find his take-off speed and ″air time″ using constant-acceleration equations, and use the latter, together with the definition of rotational velocity, to find his initial rotational velocity. Finally, we can apply conservation of angular momentum to find his initial angular momentum.

Using a constant-acceleration equation, relate his takeoff speed v_0 to his maximum elevation Δy:

$$v^2 = v_{0y}^2 + 2a_y\Delta y$$

or, because $v_{0y} = v_0\sin(45°)$, $v = 0$, and $a_y = -g$,

$$0 = v_0^2\sin^2 45° - 2g\Delta y$$

Solving for v_0 and simplifying yields:

$$v_0 = \sqrt{\frac{2g\Delta y}{\sin^2 45°}} = \frac{\sqrt{2g\Delta y}}{\sin 45°}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \frac{\sqrt{2\left(9.81\,\text{m/s}^2\right)\left(0.60\,\text{m}\right)}}{\sin 45°} = \boxed{4.9\,\text{m/s}}$$

Use its definition to express Goebel's angular velocity:

$$\omega = \frac{\Delta\theta}{\Delta t}$$

Use a constant-acceleration equation to express Goebel's ″air time″ Δt:

$$\Delta t = 2\Delta t_{\text{rise }0.6\text{ m}} = 2\sqrt{\frac{2\Delta y}{g}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = 2\sqrt{\frac{2\left(0.60\,\text{m}\right)}{9.81\,\text{m/s}^2}} = 0.699\,\text{s}$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{4\,\text{rev}}{0.699\,\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}} = \boxed{36\,\text{rad/s}}$$

Use conservation of angular momentum to relate his take-off angular velocity ω_0 to his average angular velocity ω as he performs a quadruple Lutz:

$$I_0\omega_0 = I\omega$$

Assuming that he can change his moment of inertia by a factor of 2 by pulling his arms in, solve for and evaluate ω_0:

$$\omega_0 = \frac{I}{I_0}\omega = \frac{1}{2}(36\,\text{rad/s}) = \boxed{18\,\text{rad/s}}$$

Express his take-off angular momentum:

$$L_0 = I_0\omega_0$$

Assuming that we can model him as a solid cylinder of length ℓ with an average radius r and mass m, express his moment of inertia with arms outstretched (his take-off configuration):

$$I_0 = 2\left(\tfrac{1}{2}mr^2\right) = mr^2$$

where the factor of 2 represents our assumption that he can double his moment of inertia by extending his arms.

Substituting for I_0 gives:

$$L_0 = mr^2\omega_0$$

Substitute numerical values and evaluate L_0:

$$L_0 = (60\,\text{kg})(0.15\,\text{m})^2(18\,\text{rad/s}) = \boxed{24\,\text{kg}\cdot\text{m}^2/\text{s}}$$

The Vector Product and the Vector Nature of Torque and Rotation

27 • [SSM] A force of magnitude F is applied horizontally in the negative x direction to the rim of a disk of radius R as shown in Figure 10-42. Write $\vec{F}$ and $\vec{r}$ in terms of the unit vectors $\hat{i}$, $\hat{j}$, and $\hat{k}$, and compute the torque produced by this force about the origin at the center of the disk.

Picture the Problem We can express $\vec{F}$ and $\vec{r}$ in terms of the unit vectors $\hat{i}$ and $\hat{j}$ and then use the definition of the vector product to find $\vec{\tau}$.

Express $\vec{F}$ in terms of F and the unit vector $\hat{i}$:

$$\vec{F} = -F\hat{i}$$

Express $\vec{r}$ in terms of R and the unit vector $\hat{j}$:

$$\vec{r} = R\hat{j}$$

Calculate the vector product of $\vec{r}$ and $\vec{F}$:

$$\vec{\tau} = \vec{r}\times\vec{F} = FR\left(\hat{j}\times -\hat{i}\right) = FR\left(\hat{i}\times\hat{j}\right) = \boxed{FR\,\hat{k}}$$

28 • Compute the torque about the origin of the gravitational force $\vec{F} = -mg\hat{j}$ acting on a particle of mass m located at $\vec{r} = x\hat{i} + y\hat{j}$ and show that this torque is independent of the y coordinate.

Picture the Problem We can find the torque from the vector product of $\vec{r}$ and $\vec{F}$.

Compute the vector product of $\vec{r}$ and $\vec{F}$:

$$\vec{\tau} = \vec{r} \times \vec{F} = \left(x\hat{i} + y\hat{j}\right)\left(-mg\hat{j}\right)$$
$$= -mgx\left(\hat{i} \times \hat{j}\right) - mgy\left(\hat{j} \times \hat{j}\right)$$
$$= \boxed{-mgx\hat{k}}$$

29 • Find $\vec{A} \times \vec{B}$ for the following choices: (a) $\vec{A} = 4\hat{i}$ and $\vec{B} = 6\hat{i} + 6\hat{j}$, ($b$) $\vec{A} = 4\hat{i}$ and $\vec{B} = 6\hat{i} + 6\hat{k}$, and ($c$) $\vec{A} = 2\hat{i} + 3\hat{j}$ and $\vec{B} = 3\hat{i} + 2\hat{j}$.

Picture the Problem We can use the definitions of the vector products of the unit vectors $\hat{i}$, $\hat{j}$, and $\hat{k}$ to evaluate $\vec{A} \times \vec{B}$ in each case.

(a) Evaluate $\vec{A} \times \vec{B}$ for $\vec{A} = 4\hat{i}$ and $\vec{B} = 6\hat{i} + 6\hat{j}$:

$$\vec{A} \times \vec{B} = 4\hat{i} \times \left(6\hat{i} + 6\hat{j}\right)$$
$$= 24\left(\hat{i} \times \hat{i}\right) + 24\left(\hat{i} \times \hat{j}\right)$$
$$= 24(0) + 24\hat{k}$$
$$= \boxed{24\hat{k}}$$

(b) Evaluate $\vec{A} \times \vec{B}$ for $\vec{A} = 4\hat{i}$ and $\vec{B} = 6\hat{i} + 6\hat{k}$:

$$\vec{A} \times \vec{B} = 4\hat{i} \times \left(6\hat{i} + 6\hat{k}\right)$$
$$= 24\left(\hat{i} \times \hat{i}\right) + 24\left(\hat{i} \times \hat{k}\right)$$
$$= 24(0) + 24\left(-\hat{j}\right)$$
$$= \boxed{-24\hat{j}}$$

(c) Evaluate $\vec{A} \times \vec{B}$ for $\vec{A} = 2\hat{i} + 3\hat{j}$ and $\vec{B} = 3\hat{i} + 2\hat{j}$:

$$\vec{A} \times \vec{B} = \left(2\hat{i} + 3\hat{j}\right) \times \left(3\hat{i} + 2\hat{j}\right)$$
$$= 6\left(\hat{i} \times \hat{i}\right) + 4\left(\hat{i} \times \hat{j}\right) + 9\left(\hat{j} \times \hat{i}\right)$$
$$+ 6\left(\hat{j} \times \hat{j}\right)$$
$$= 6(0) + 4\left(\hat{k}\right) + 9\left(-\hat{k}\right) + 6(0)$$
$$= \boxed{-5\hat{k}}$$

30 •• For each case in Problem 31, compute $\left|\vec{A} \times \vec{B}\right|$. Compare it to $\left|\vec{A}\right|\left|\vec{B}\right|$ to estimate which of the pairs of vectors are closest to being perpendicular. Verify your answers by calculating the angle using the dot product.

Picture the Problem Because $\left|\vec{A}\times\vec{B}\right| = \left|\vec{A}\right|\left|\vec{B}\right|\sin\phi$, if vectors $\vec{A}$ and $\vec{B}$ are perpendicular, then $\left|\vec{A}\times\vec{B}\right| = \vec{A}\left|\vec{B}\right|$ or $\dfrac{\left|\vec{A}\times\vec{B}\right|}{\left|\vec{A}\right|\left|\vec{B}\right|} = 1$. The scalar product of vectors $\vec{A}$ and $\vec{B}$ is $\vec{A}\cdot\vec{B} = \left|\vec{A}\right|\left|\vec{B}\right|\cos\phi$. We can verify our estimations using this definition to calculate ϕ for each pair of vectors.

(*a*) For $\vec{A} = 4\hat{i}$ and $\vec{B} = 6\hat{i} + 6\hat{j}$:

$$\frac{\left|\vec{A}\times\vec{B}\right|}{\left|\vec{A}\right|\left|\vec{B}\right|} = \frac{\left|4\hat{i}\times\left(6\hat{i}+6\hat{j}\right)\right|}{(4)\left(6\sqrt{2}\right)} = \frac{\left|24\hat{k}\right|}{24\sqrt{2}} = \frac{1}{\sqrt{2}}$$
$$\approx 0.707$$

and the vectors $\vec{A}$ and $\vec{B}$ are not perpendicular.

The angle between $\vec{A}$ and $\vec{B}$ is:

$$\phi = \cos^{-1}\left(\frac{\vec{A}\cdot\vec{B}}{\left|\vec{A}\right|\left|\vec{B}\right|}\right) = \cos^{-1}\left(\frac{4\hat{i}\cdot\left(6\hat{i}+6\hat{j}\right)}{24\sqrt{2}}\right)$$
$$= \cos^{-1}\frac{24}{24\sqrt{2}} = 45°,$$

a result confirming that obtained above.

(*b*) For $\vec{A} = 4\hat{i}$ and $\vec{B} = 6\hat{i} + 6\hat{k}$:

$$\frac{\left|\vec{A}\times\vec{B}\right|}{\left|\vec{A}\right|\left|\vec{B}\right|} = \frac{\left|4\hat{i}\times\left(6\hat{i}+6\hat{k}\right)\right|}{(4)\left(6\sqrt{2}\right)} = \frac{\left|-24\hat{j}\right|}{24\sqrt{2}} = \frac{1}{\sqrt{2}}$$
$$\approx 0.707$$

and the vectors $\vec{A}$ and $\vec{B}$ are not perpendicular.

The angle between $\vec{A}$ and $\vec{B}$ is:

$$\phi = \cos^{-1}\left(\frac{\vec{A}\cdot\vec{B}}{\left|\vec{A}\right|\left|\vec{B}\right|}\right) = \cos^{-1}\left(\frac{4\hat{i}\cdot\left(6\hat{i}+6\hat{k}\right)}{24\sqrt{2}}\right)$$
$$= \cos^{-1}\frac{24}{24\sqrt{2}} = 45°,$$

a result confirming that obtained above.

(*c*) For $\vec{A} = 2\hat{i} + 3\hat{j}$ and $\vec{B} = 3\hat{i} + 2\hat{j}$:

$$\frac{\left|\vec{A}\times\vec{B}\right|}{\left|\vec{A}\right|\left|\vec{B}\right|} = \frac{\left|\left(2\hat{i}+3\hat{j}\right)\times\left(3\hat{i}+2\hat{j}\right)\right|}{\sqrt{13}\sqrt{13}} = \frac{\left|-5\hat{k}\right|}{13}$$

$$= \frac{5}{13} \approx 0.385$$

and the vectors $\vec{A}$ and $\vec{B}$ are not perpendicular.

The angle between $\vec{A}$ and $\vec{B}$ is:

$$\phi = \cos^{-1}\left(\frac{\vec{A}\cdot\vec{B}}{\left|\vec{A}\right|\left|\vec{B}\right|}\right)$$

$$= \cos^{-1}\left(\frac{\left(2\hat{i}+3\hat{j}\right)\cdot\left(3\hat{i}+2\hat{j}\right)}{\sqrt{13}\sqrt{13}}\right)$$

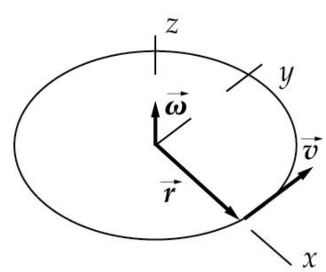
$$= \cos^{-1}\left(\frac{12}{13}\right) = 23°,$$

a result confirming that obtained above.

While none of these sets of vectors are perpendicular, those in (*a*) and (*b*) are the closest, with $\phi = 45°$, to being perpendicular.

31 •• A particle moves in a circle that is centered at the origin. The particle has position $\vec{r}$ and angular velocity $\vec{\omega}$. (*a*) Show that its velocity is given by $\vec{v} = \vec{\omega}\times\vec{r}$. (*b*) Show that its centripetal acceleration is given by $\vec{a}_c = \vec{\omega}\times\vec{v} = \vec{\omega}\times\left(\vec{\omega}\times\vec{r}\right)$.

Picture the Problem Let $\vec{r}$ be in the *xy* plane and point in the +*x* direction. Then $\vec{\omega}$ points in the +*z* direction. We can establish the results called for in this problem by forming the appropriate vector products and by differentiating $\vec{v}$.



(*a*) Express $\vec{\omega}$ using unit vector notation:

$$\vec{\omega} = \omega\hat{k}$$

Express $\vec{r}$ using unit vector notation:

$$\vec{r} = r\hat{i}$$

Form the vector product of $\vec{\omega}$ and $\vec{r}$:

$$\vec{\omega}\times\vec{r} = \omega\hat{k}\times r\hat{i} = r\omega\left(\hat{k}\times\hat{i}\right) = r\omega\,\hat{j}$$

$$= v\hat{j}$$

and $\vec{v} = \boxed{\vec{\omega}\times\vec{r}}$

(*b*) Differentiate $\vec{v}$ with respect to *t* to express $\vec{a}$:

$$\vec{a} = \frac{d\vec{v}}{dt} = \frac{d}{dt}(\vec{\omega}\times\vec{r}) = \frac{d\vec{\omega}}{dt}\times\vec{r} + \vec{\omega}\times\frac{d\vec{r}}{dt} = \frac{d\vec{\omega}}{dt}\times\vec{r} + \vec{\omega}\times\vec{v} = \vec{a}_\mathrm{t} + \vec{\omega}\times(\vec{\omega}\times\vec{r})$$
$$= \vec{a}_\mathrm{t} + \vec{a}_\mathrm{c}$$

where $\vec{a}_\mathrm{c} = \boxed{\vec{\omega}\times(\vec{\omega}\times\vec{r})}$ and $\vec{a}_\mathrm{t}$ and $\vec{a}_\mathrm{c}$ are the tangential and centripetal accelerations, respectively.

32 •• You are given three vectors and their components in the form: $\vec{A} = a_x\hat{i} + a_y\hat{j} + a_z\hat{k}$, $\vec{B} = b_x\hat{i} + b_y\hat{j} + b_z\hat{k}$, and $\vec{C} = c_x\hat{i} + c_y\hat{j} + c_z\hat{k}$. Show that the following equalities hold: $\vec{A}\cdot(\vec{B}\times\vec{C}) = \vec{C}\cdot(\vec{A}\times\vec{B}) = \vec{B}\cdot(\vec{C}\times\vec{A})$

Picture the Problem We can establish these equalities by carrying out the details of the vector- and scalar-products and comparing the results of these operations.

Evaluate the vector product of $\vec{B}$ and $\vec{C}$ to obtain:

$$\vec{B}\times\vec{C} = (b_yc_z - b_zc_y)\hat{i} + (b_zc_x - b_xc_z)\hat{j} + (b_xc_y - b_yc_x)\hat{k}$$

Form the scalar product of $\vec{A}$ with $\vec{B}\times\vec{C}$ to obtain:

$$\vec{A}\cdot(\vec{B}\times\vec{C}) = a_xb_yc_z - a_xb_zc_y + a_yb_zc_x - a_yb_xc_z + a_zb_xc_y - a_zb_yc_x \qquad (1)$$

Evaluate the vector product of $\vec{A}$ and $\vec{B}$ to obtain:

$$\vec{A}\times\vec{B} = (a_yb_z - a_zb_y)\hat{i} + (a_zb_x - a_xb_z)\hat{j} + (a_xb_y - a_yb_x)\hat{k}$$

Form the scalar product of $\vec{C}$ with $\vec{A}\times\vec{B}$ to obtain:

$$\vec{C}\cdot(\vec{A}\times\vec{B}) = c_xa_yb_z - c_xa_zb_y + c_ya_zb_x - c_ya_xb_z + c_za_xb_y - c_za_yb_x \qquad (2)$$

Evaluate the vector product of $\vec{C}$ and $\vec{A}$ to obtain:

$$\vec{C}\times\vec{A} = (c_ya_z - a_za_y)\hat{i} + (c_za_x - a_xa_z)\hat{j} + (c_xa_y - a_ya_x)\hat{k}$$

Form the scalar product of $\vec{B}$ with $\vec{C}\times\vec{A}$ to obtain:

$$\vec{B}\cdot(\vec{C}\times\vec{A}) = b_xc_ya_z - b_xc_za_y + b_yc_za_x - b_yc_xa_z + b_zc_xa_y - b_zc_ya_x \qquad (3)$$

The equality of equations (1), (2), and (3) establishes the equalities.

33 •• If $\vec{A} = 3\hat{j}$, $\vec{A}\times\vec{B} = 9\hat{i}$, and $\vec{A}\cdot\vec{B} = 12$, find $\vec{B}$.

Picture the Problem We can write $\vec{B}$ in the form $\vec{B} = B_x\hat{i} + B_y\hat{j} + B_z\hat{k}$ and use the scalar product of $\vec{A}$ and $\vec{B}$ to find B_y and their vector product to find B_x and B_z.

Express $\vec{B}$ in terms of its components:

$$\vec{B} = B_x\hat{i} + B_y\hat{j} + B_z\hat{k} \qquad (1)$$

Evaluate $\vec{A}\cdot\vec{B}$:

$$\vec{A}\cdot\vec{B} = 3B_y = 12 \Rightarrow B_y = 4$$

Evaluate $\vec{A}\times\vec{B}$:

$$\vec{A}\times\vec{B} = 3\hat{j}\times\left(B_x\hat{i} + 4\hat{j} + B_z\hat{k}\right) = -3B_x\hat{k} + 3B_z\hat{i}$$

Because $\vec{A}\times\vec{B} = 9\hat{i}$:

$B_x = 0$ and $B_z = 3$.

Substitute for B_y and B_z in equation (1) to obtain:

$$\vec{B} = \boxed{4\hat{j} + 3\hat{k}}$$

34 •• If $\vec{A} = 4\hat{i}$, $B_z = 0$, $\left|\vec{B}\right| = 5$, and $\vec{A}\times\vec{B} = 12\hat{k}$, determine $\vec{B}$.

Picture the Problem Because $B_z = 0$, we can express $\vec{B}$ as $\vec{B} = B_x\hat{i} + B_y\hat{j}$ and form its vector product with $\vec{A}$ to determine B_x and B_y.

Express $\vec{B}$ in terms of its components:

$$\vec{B} = B_x\hat{i} + B_y\hat{j} \qquad (1)$$

Express $\vec{A}\times\vec{B}$:

$$\vec{A}\times\vec{B} = 4\hat{i}\times\left(B_x\hat{i} + B_y\hat{j}\right) = 4B_y\hat{k} = 12\hat{k}$$

Solving for B_y yields:

$$B_y = 3$$

Relate B to B_x and B_y:

$$B^2 = B_x^2 + B_y^2$$

Solve for and evaluate B_x:

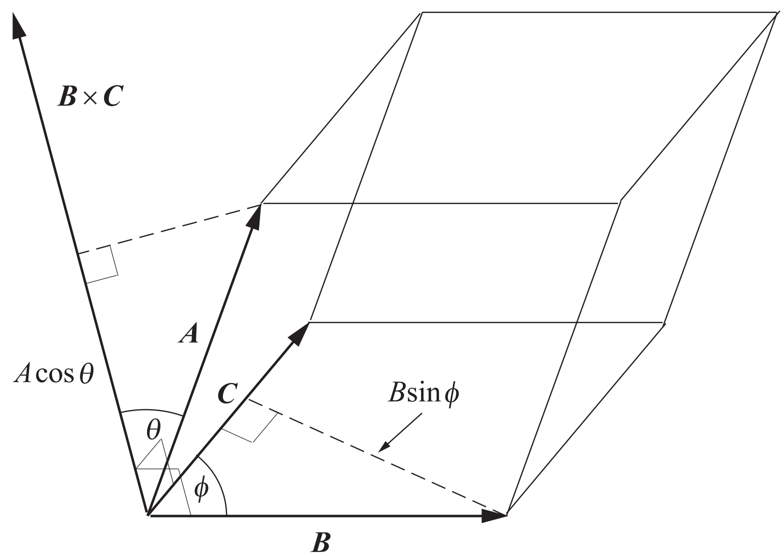
$$B_x = \sqrt{B^2 - B_y^2} = \sqrt{5^2 - 3^2} = 4$$

Substitute for B_x and B_y in equation (1) to obtain:

$$\vec{B} = \boxed{4\hat{i} + 3\hat{j}}$$

35 ••• Given three noncoplanar vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$, show that $\vec{A}\cdot\left(\vec{B}\times\vec{C}\right)$ is the volume of the parallelepiped formed by the three vectors.

Picture the Problem Let, without loss of generality, the vector $\vec{C}$ lie along the x axis and the vector $\vec{B}$ lie in the xy plane as shown below to the left. The diagram to the right shows the parallelepiped spanned by the three vectors. We can apply the definitions of the vector- and scalar-products to show that $\vec{A}\cdot\left(\vec{B}\times\vec{C}\right)$ is the volume of the parallelepiped.



The magnitude of the vector product of $\vec{B}$ and $\vec{C}$ is:

$$\left|\vec{B}\times\vec{C}\right| = BC\sin\phi$$

and

$$\begin{aligned}\left|\vec{B}\times\vec{C}\right| &= (B\sin\phi)C \\ &= \text{area of the base parallelogram}\end{aligned}$$

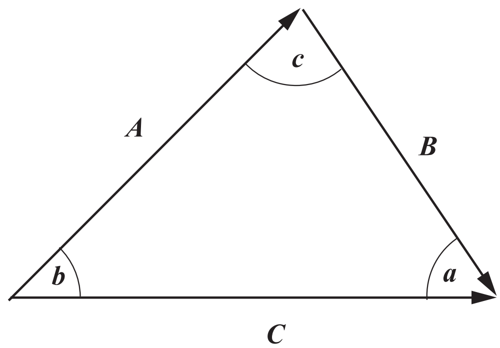
Forming the scalar-product of $\vec{A}$ with the vector-product of $\vec{B}$ and $\vec{C}$ gives:

$$\begin{aligned}\vec{A}\cdot\left(\vec{B}\times\vec{C}\right) &= A(B\sin\phi)C\cos\theta \\ &= (BC\sin\phi)(A\cos\theta) \\ &= (\text{area of base})(\text{height}) \\ &= \boxed{V_{\text{parallelepiped}}}\end{aligned}$$

36 ••• Using the cross product, prove the *law of sines* for the triangle shown in Figure 10-43. That is, if A, B, and C are the lengths of each side of the triangle, show that $A/\sin a = B/\sin b = C/\sin c$.

Picture the Problem Draw the triangle using the three vectors as shown below. Note that $\vec{A}+\vec{B}=\vec{C}$. We can find the magnitude of the vector product of $\vec{A}$ and $\vec{B}$ and of $\vec{A}$ and $\vec{C}$ and then use the vector product of $\vec{A}$ and $\vec{C}$, using

$\vec{A}+\vec{B}=\vec{C},$ to show that $AC\sin b = AB\sin c$ or $\dfrac{B}{\sin b}=\dfrac{C}{\sin c}$. Proceeding similarly, we can extend the law of sines to the third side of the triangle and the angle opposite it.



Express the magnitude of the vector product of $\vec{A}$ and $\vec{B}$:

$$\left|\vec{A}\times\vec{B}\right| = AB\sin\left(180° - c\right) = AB\sin c$$

Express the magnitude of the vector product of $\vec{A}$ and $\vec{C}$:

$$\left|\vec{A}\times\vec{C}\right| = AC\sin b$$

Form the vector product of $\vec{A}$ with $\vec{C}$ to obtain:

$$\begin{aligned}\vec{A}\times\vec{C} &= \vec{A}\times\left(\vec{A}+\vec{B}\right)\\ &= \vec{A}\times\vec{A}+\vec{A}\times\vec{B}\\ &= \vec{A}\times\vec{B}\end{aligned}$$

because $\vec{A}\times\vec{A}=0$.

Because $\vec{A}\times\vec{C}=\vec{A}\times\vec{B}$:

$$\left|\vec{A}\times\vec{C}\right| = \left|\vec{A}\times\vec{B}\right|$$

and

$$AC\sin b = AB\sin c$$

Simplify and rewrite this expression to obtain:

$$\boxed{\frac{B}{\sin b}=\frac{C}{\sin c}}$$

Proceed similarly to extend this result to the law of sines:

$$\boxed{\frac{A}{\sin a}=\frac{B}{\sin b}=\frac{C}{\sin c}}$$

Torque and Angular Momentum

37 • [SSM] A 2.0-kg particle moves directly eastward at a constant speed of 4.5 m/s along an east-west line. (*a*) What is its angular momentum (including direction) about a point that lies 6.0 m north of the line? (*b*) What is its angular momentum (including direction) about a point that lies 6.0 m south of the line?

(*c*) What is its angular momentum (including direction) about a point that lies 6.0 m directly east of the particle?

Picture the Problem The angular momentum of the particle is $\vec{L} = \vec{r} \times \vec{p}$ where $\vec{r}$ is the vector locating the particle relative to the reference point and $\vec{p}$ is the particle's linear momentum.

(*a*) The magnitude of the particle's angular momentum is given by:

$$L = rp\sin\phi = rmv\sin\phi = mv(r\sin\phi)$$

Substitute numerical values and evaluate *L*:

$$L = (2.0\,\text{kg})(4.5\,\text{m/s})(6.0\,\text{m}) = 54\,\text{kg}\cdot\text{m}^2/\text{s}$$

Use a right-hand rule to establish the direction of $\vec{L}$:

$$L = \boxed{54\,\text{kg}\cdot\text{m}^2/\text{s, upward}}$$

(*b*) Because the distance to the line along which the particle is moving is the same, only the direction of $\vec{L}$ differs:

$$L = \boxed{54\,\text{kg}\cdot\text{m}^2/\text{s, downward}}$$

(*c*) Because $\vec{r} \times \vec{p} = 0$ for a point on the line along which the particle is moving:

$$\vec{L} = \boxed{0}$$

38 • You observe a 2.0-kg particle moving at a constant speed of 3.5 m/s in a clockwise direction around a circle of radius 4.0 m. (*a*) What is its angular momentum (including direction) about the center of the circle? (*b*) What is its moment of inertia about an axis through the center of the circle and perpendicular to the plane of the motion? (*c*) What is the angular velocity of the particle?

Picture the Problem The angular momentum of the particle is $\vec{L} = \vec{r} \times \vec{p}$ where $\vec{r}$ is the vector locating the particle relative to the reference point and $\vec{p}$ is the particle's linear momentum.

(*a*) The magnitude of the particle's angular momentum is given by:

$$L = rp\sin\phi = rmv\sin\phi = mv(r\sin\phi)$$

Substitute numerical values and evaluate the magnitude of *L*:

$$L = (2.0\,\text{kg})(3.5\,\text{m/s})(4.0\,\text{m}) = 28\,\text{kg}\cdot\text{m}^2/\text{s}$$

Use a right-hand rule to establish the direction of $\vec{L}$: $L = \boxed{28\,\text{kg}\cdot\text{m}^2/\text{s, away from you}}$

(*b*) Treat the 2.0-kg particle as a point particle to obtain: $I = mr^2$

Substitute numerical values and evaluate *I*: $I = (2.0\,\text{kg})(4.0\,\text{m})^2 = \boxed{32\,\text{kg}\cdot\text{m}^2}$

(*c*) Because $L = I\omega$, the angular speed of the particle is the ratio of its angular momentum and its moment of inertia: $\omega = \frac{L}{I}$

Substitute numerical values and evaluate ω: $\omega = \frac{28\,\text{kg}\cdot\text{m}^2/\text{s}}{32\,\text{kg}\cdot\text{m}^2} = \boxed{0.88\,\text{rad/s}^2}$

39 •• (*a*) A particle moving at constant velocity has zero angular momentum about a particular point. Use the definition of angular momentum to show that under this condition the particle is moving either directly toward or directly away from the point. (*b*) You are a right-handed batter and let a waist-high fastball go past you without swinging. What is the direction of its angular momentum relative to your navel? (Assume the ball travels in a straight horizontal line as it passes you.)

Picture the Problem $\vec{L}$ and $\vec{p}$ are related according to $\vec{L} = \vec{r}\times\vec{p}$. If $\vec{L} = 0$, then examination of the magnitude of $\vec{r}\times\vec{p}$ will allow us to conclude that $\sin\phi = 0$ and that the particle is moving either directly toward the point, directly away from the point, or through the point.

(*a*) Because $\vec{L} = 0$: $\vec{r}\times\vec{p} = \vec{r}\times m\vec{v} = m\vec{r}\times\vec{v} = 0$

or

$\vec{r}\times\vec{v} = 0$

Express the magnitude of $\vec{r}\times\vec{v}$: $|\vec{r}\times\vec{v}| = rv\sin\phi = 0$

Because neither *r* nor *v* is zero: $\sin\phi = 0$

where ϕ is the angle between $\vec{r}$ and $\vec{v}$.

Solving for ϕ yields: $\phi = \sin^{-1}(0) = \boxed{0°\text{ or }180°}$

(*b*) Use the right-hand rule to establish that the ball's angular momentum is downward.

40 •• A particle that has a mass m is traveling with a constant velocity $\vec{v}$ along a straight line that is a distance b from the origin O (Figure 10-44). Let dA be the area swept out by the position vector from O to the particle during a time interval dt. Show that dA/dt is constant and is equal to $L/2m$, where L is the magnitude of the angular momentum of the particle about the origin.

Picture the Problem The area swept out by the position vector (the shaded area in Figure 10-44) is the difference between the area of a trapezoid and the area of a triangle. Let x_1 be the x component of $\vec{r}_1$ and $x_1 + \Delta x$ be the x component of $\vec{r}_2$. Use the formulas for the areas of a trapezoid and a triangle to express ΔA and then take the limit as $\Delta t \to 0$ to express dA/dt. Letting θ be the angle between $\vec{r}_1$ and the horizontal axis, we can express b as a function of $|\vec{r}_1|$ and θ.

The area swept out by the position vector (the shaded area in Figure 10-44) is given by:

$$\begin{aligned}\Delta A &= A_{\text{trap}} - A_{\text{triangle}}\\ &= \tfrac{1}{2}b[\Delta x + (x_1 + \Delta x)] - \tfrac{1}{2}b(x_1 + \Delta x)\\ &= \tfrac{1}{2}b\Delta x\end{aligned}$$

In the limit as $\Delta t \to 0$:

$$\frac{dA}{dt} = \tfrac{1}{2}b\frac{dx}{dt} = \tfrac{1}{2}bv = \text{constant}$$

Because $b = |\vec{r}_1|\sin\theta$:

$$\begin{aligned}\frac{dA}{dt} &= \tfrac{1}{2}bv = \tfrac{1}{2}(|\vec{r}_1|\sin\theta)v = \frac{(|\vec{r}_1|\sin\theta)mv}{2m}\\ &= \frac{1}{2m}(|\vec{r}_1|p\sin\theta) = \boxed{\frac{L}{2m}}\end{aligned}$$

41 •• A 15-g coin that has a diameter of 1.5 cm is spinning at 10 rev/s about a fixed vertical axis. The coin is spinning on edge with its center directly above the point of contact with the tabletop. As you look down on the tabletop, the coin spins clockwise. (*a*) What is the angular momentum (including direction) of the coin about its center of mass? (To find the moment of inertia about the axis, see Table 9-1.) Model the coin as a cylinder of length L and take the limit as L approaches zero. (*b*) What is the coin's angular momentum (including direction) about a point on the tabletop 10 cm from the axis? (*c*) Now the coin's center of mass travels at 5.0 cm/s in a straight line east across the tabletop, while spinning the same way as in Part (*a*). What is the angular momentum (including direction) of the coin about a point on the line of motion of the center of mass? (*d*) When it is both spinning and sliding, what is the angular momentum of the coin (including direction) about a point 10 cm north of the line of motion of the center of mass?

Picture the Problem We can find the total angular momentum of the coin from the sum of its spin and orbital angular momenta.

(*a*) The spin angular momentum of the coin is:

$$L_{\text{spin}} = I\omega_{\text{spin}}$$

From Table 9-1, for *L* negligible compared to *R*:

$$I = \tfrac{1}{4}MR^2$$

Substitute for *I* to obtain:

$$L_{\text{spin}} = \tfrac{1}{4}MR^2\omega_{\text{spin}}$$

Substitute numerical values and evaluate L_{spin}:

$$L_{\text{spin}} = \tfrac{1}{4}(0.015\,\text{kg})(0.0075\,\text{m})^2\left(10\frac{\text{rev}}{\text{s}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\right) = 1.33\times10^{-5}\ \text{kg}\cdot\text{m}^2/\text{s}$$

Use a right-hand rule to establish the direction of $\vec{L}_{\text{spin}}$:

$$L_{\text{spin}} = \boxed{1.3\times10^{-5}\ \text{kg}\cdot\text{m}^2/\text{s, away from you.}}$$

(*b*)The total angular momentum of the coin is the sum of its orbital and spin angular momenta:

$$L_{\text{total}} = L_{\text{orbital}} + L_{\text{spin}}$$

Substitute numerical values and evaluate L_{total}:

$$L_{\text{total}} = 0 + L_{\text{spin}} = 1.3\times10^{-5}\ \text{kg}\cdot\text{m}^2/\text{s}$$

Use a right-hand rule to establish the direction of $\vec{L}_{\text{total}}$:

$$L_{\text{total}} = \boxed{1.3\times10^{-5}\ \text{kg}\cdot\text{m}^2/\text{s, away from you}}$$

(*c*) Because $L_{\text{orbital}} = 0$:

$$L_{\text{total}} = \boxed{1.3\times10^{-5}\ \text{kg}\cdot\text{m}^2/\text{s, away from you}}$$

(*d*) When it is both spinning and sliding, the total angular momentum of the coin is:

$$L_{\text{total}} = L_{\text{orbital}} + L_{\text{spin}}$$

The orbital angular momentum of the coin is: $L_{\text{orbital}} = MvR$

The spin angular momentum of the coin is: $L_{\text{spin}} = I_{\text{spin}}\omega_{\text{spin}} = \frac{1}{4}MR^2\omega_{\text{spin}}$

Substituting for L_{orbital} and L_{spin} yields: $L_{\text{total}} = MvR + \frac{1}{4}MR^2\omega_{\text{spin}}$

Substitute numerical values and evaluate L_{total}:

$$L_{\text{total}} = (0.015\,\text{kg})(0.050\,\text{m/s})(0.10\,\text{m}) + \frac{1}{4}(0.015\,\text{kg})(0.0075\,\text{m})^2\left(10\,\frac{\text{rev}}{\text{s}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\right)$$
$$= \boxed{8.8\times10^{-5}\,\text{kg}\cdot\text{m}^2\text{/s, pointing toward you}}$$

42 •• (*a*) Two stars of masses m_1 and m_2 are located at $\vec{r}_1$ and $\vec{r}_2$ relative to some origin *O*, as shown in Figure 10-45. They exert equal and opposite attractive gravitational forces on each other. For this two-star system, calculate the net torque exerted by these internal forces about the origin *O* and show that it is zero only if both forces lie along the line joining the particles. (*b*)The fact that the Newton's third-law pair of forces are not only equal and oppositely directed but also lie along the line connecting the two objects is sometimes called the strong form of Newton's third law. Why is it important to add that last phrase? *Hint: Consider what would happen to these two objects if the forces were offset from each other.*

Picture the Problem Both the forces acting on the particles exert torques with respect to an axis perpendicular to the page and through point O and the net torque about this axis is their vector sum.

(*a*) The net torque about an axis perpendicular to the page and through point O is given by:

$$\vec{\tau}_{\text{net}} = \sum_{\text{i}} \vec{\tau}_{\text{i}} = \vec{r}_1 \times \vec{F}_1 + \vec{r}_2 \times \vec{F}_2$$

or, because $\vec{F}_2 = -\vec{F}_1$,

$$\vec{\tau}_{\text{net}} = (\vec{r}_1 - \vec{r}_2)\times\vec{F}_1$$

Because $\vec{r}_1 - \vec{r}_2$ points along $-\vec{F}_1$: $\vec{\tau}_{\text{net}} = (\vec{r}_1 - \vec{r}_2)\times\vec{F}_1 = \boxed{0}$

(*b*) If the forces are not along the same line, there will be a net torque (but still no net force) acting on the system. This net torque would cause the system to accelerate angularly, contrary to observation, and hence makes no sense physically.

43 •• A 1.8-kg particle moves in a circle of radius 3.4 m. As you look down on the plane of its orbit, it is initially moving clockwise. If we call the clockwise direction positive, its angular momentum relative to the center of the circle varies with time according to $L(t) = 10\ \mathrm{N\cdot m\cdot s} - (4.0\ \mathrm{N\cdot m})t$. (*a*) Find the magnitude and direction of the torque acting on the particle. (*b*) Find the angular velocity of the particle as a function of time.

Picture the Problem The angular momentum of the particle changes because a *net* torque acts on it. Because we know how the angular momentum depends on time, we can find the net torque acting on the particle by differentiating its angular momentum. We can use a constant-acceleration equation and Newton's second law to relate the angular speed of the particle to its angular acceleration.

(*a*) The magnitude of the torque acting on the particle is the rate at which its angular momentum changes:

$$\tau_{\text{net}} = \frac{dL}{dt}$$

Evaluate dL/dt to obtain:

$$\tau_{\text{net}} = \frac{d}{dt}\left[10\ \mathrm{N\cdot m\cdot s} - (4.0\ \mathrm{N\cdot m})t\right] = \boxed{-4.0\ \mathrm{N\cdot m}}$$

Note that, because L decreases as the particle rotates clockwise, the angular acceleration and the net torque are both upward.

(*b*) The angular speed of the particle is given by:

$$\omega_{\text{orbital}} = \frac{L_{\text{orbital}}}{I_{\text{orbital}}}$$

Treating the 1.8-kg particle as a point particle, express its moment of inertia relative to an axis through the center of the circle and normal to it:

$$I_{\text{orbital}} = MR^2$$

Substitute for I_{orbital} and L_{orbital} to obtain:

$$\omega_{\text{orbital}} = \frac{10\ \mathrm{N\cdot m\cdot s} - (4.0\ \mathrm{N\cdot m})t}{MR^2}$$

Substitute numerical values and evaluate ω_{orbital}:

$$\omega_{\text{orbital}} = \frac{10\,\text{N}\cdot\text{m}\cdot\text{s} - (4.0\,\text{N}\cdot\text{m})t}{(1.8\,\text{kg})(3.4\,\text{m})^2} = \boxed{0.48\,\text{rad/s} - (0.19\,\text{rad/s}^2)t}$$

Note that the direction of the angular velocity is downward.

44 •• You are designing a lathe motor and part of it consists of a uniform cylinder whose mass is 90 kg and radius is 0.40 m that is mounted so that it turns without friction on its axis, which is fixed. The cylinder is driven by a belt that wraps around its perimeter and exerts a constant torque. At $t = 0$, the cylinder's angular velocity is zero. At $t = 25$ s, its angular speed is 500 rev/min. (*a*) What is the magnitude of its angular momentum at $t = 25$ s? (*b*) At what rate is the angular momentum increasing? (*c*) What is the magnitude of the torque acting on the cylinder? (*d*) What is the magnitude of the frictional force acting on the rim of the cylinder?

Picture the Problem The angular momentum of the cylinder changes because a *net* torque acts on it. We can find the angular momentum at $t = 25$ s from its definition and the magnitude of the *net* torque acting on the cylinder from the rate at which the angular momentum is changing. The magnitude of the frictional force acting on the rim can be found using the definition of torque.

(*a*) The angular momentum of the cylinder is given by:

$$L = I\omega = \tfrac{1}{2}mr^2\omega$$

Substitute numerical values and evaluate L:

$$L = \tfrac{1}{2}(90\,\text{kg})(0.40\,\text{m})^2\left(500\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}\right)$$
$$= 377\,\text{kg}\cdot\text{m}^2/\text{s} = \boxed{3.8\times10^2\,\text{kg}\cdot\text{m}^2/\text{s}}$$

(*b*) The rate at which the angular momentum of the cylinder is increasing is given by:

$$\frac{dL}{dt} = \frac{(377\,\text{kg}\cdot\text{m}^2/\text{s})}{25\,\text{s}} = 15\,\text{kg}\cdot\text{m}^2/\text{s}^2$$
$$= \boxed{15\,\text{kg}\cdot\text{m}^2/\text{s}^2}$$

(*c*) Because the torque acting on the uniform cylinder is constant, the rate of change of the angular momentum is constant and hence the instantaneous rate of change of the angular momentum at any instant is equal to the average rate of change over the time during which the torque acts:

$$\tau = \frac{dL}{dt} = \boxed{15\,\text{kg}\cdot\text{m}^2/\text{s}^2}$$

(*d*) The magnitude of the frictional force *f* acting on the rim is:

$$f = \frac{\tau}{\ell} = \frac{15.1\,\text{kg}\cdot\text{m}^2/\text{s}^2}{0.40\,\text{m}} = \boxed{38\,\text{N}}$$

45 •• [SSM] In Figure 10-46, the incline is frictionless and the string passes through the center of mass of each block. The pulley has a moment of inertia *I* and radius *R*. (*a*) Find the net torque acting on the system (the two masses, string, and pulley) about the center of the pulley. (*b*)Write an expression for the total angular momentum of the system about the center of the pulley. Assume the masses are moving with a speed *v*. (*c*) Find the acceleration of the masses by using your results for Parts (*a*) and (*b*) and by setting the net torque equal to the rate of change of the system's angular momentum.

Picture the Problem Let the system include the pulley, string, and the blocks and assume that the mass of the string is negligible. The angular momentum of this system changes because a *net* torque acts on it. We'll take clockwise to be positive to be consistent with a positive upward velocity of the block whose mass is m_1 as indicated in the figure.

(*a*) Express the net torque about the center of mass of the pulley:

$$\tau_{\text{net}} = -m_1 gR + T_1 R - T_1 R + T_2 R + (m_2 g\sin\theta)R - Rm_1 g - T_2 R = \boxed{Rg(m_2\sin\theta - m_1)}$$

(*b*) Express the total angular momentum of the system about an axis through the center of the pulley:

$$L = I\omega + m_1 vR + m_2 vR$$

$$= \boxed{vR\left(\frac{I}{R^2} + m_1 + m_2\right)}$$

(*c*) Express τ as the time derivative of the angular momentum:

$$\tau = \frac{dL}{dt} = \frac{d}{dt}\left[vR\left(\frac{I}{R^2} + m_1 + m_2\right)\right]$$
$$= aR\left(\frac{I}{R^2} + m_1 + m_2\right)$$

Equate this result to that of Part (*a*) and solve for *a* to obtain:

$$a = \boxed{\frac{g(m_2 \sin\theta - m_1)}{\frac{I}{R^2} + m_1 + m_2}}$$

46 •• Figure 10-47 shows the rear view of a space capsule that was left rotating rapidly about its longitudinal axis at 30 rev/min after a collision with another capsule. You are the flight controller and have just moments to tell the crew how to stop this rotation before they become ill from the rotation and the situation becomes dangerous. You know that they have access to two small jets mounted tangentially at a distance of 3.0 m from the axis, as indicated in the figure. These jets can each eject 10 g/s of gas with a nozzle speed of 800 m/s. Determine the length of time these jets must run to stop the rotation. In flight, the moment of inertia of the ship about its axis (assumed constant) is known to be 4000 kg·m^2.

Picture the Problem The forces resulting from the release of gas from the jets will exert a torque on the spaceship that will slow and eventually stop its rotation. We can relate this net torque to the angular momentum of the spaceship and to the time the jets must fire.

Relate the firing time of the jets to the desired change in angular momentum:

$$\Delta t = \frac{\Delta L}{\tau_{\text{net}}} = \frac{I\Delta\omega}{\tau_{\text{net}}} \qquad (1)$$

Express the magnitude of the net torque exerted by the jets:

$$\tau_{\text{net}} = 2FR$$

Letting $\Delta m/\Delta t'$ represent the mass of gas per unit time exhausted from the jets, relate the force exerted by the gas on the spaceship to the rate at which the gas escapes:

$$F = \frac{\Delta m}{\Delta t'}v$$

Substituting for *F* yields:

$$\tau_{\text{net}} = 2vR\frac{\Delta m}{\Delta t'}$$

Substitute for τ_{net} in equation (1) to obtain:

$$\Delta t = \frac{I\Delta\omega}{2vR\dfrac{\Delta m}{\Delta t'}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{\left(4000\,\text{kg}\cdot\text{m}^2\right)\left(30\dfrac{\text{rev}}{\text{min}}\times\dfrac{2\pi\,\text{rad}}{\text{rev}}\times\dfrac{1\,\text{min}}{60\,\text{s}}\right)}{2\left(10^{-2}\,\text{kg/s}\right)\left(800\,\text{m/s}\right)\left(3.0\,\text{m}\right)} = \boxed{2.6\times10^{2}\,\text{s}}$$

47 •• A projectile (mass M) is launched at an angle θ with an initial speed v_0. Considering the torque and angular momentum about the launch point, explicitly show that $dL/dt = \tau$. Ignore the effects of air resistance. (The equations for projectile motion are found in Chapter 3.)

Picture the Problem We can use constant-acceleration equations to express the projectile's position and velocity coordinates as functions of time. We can use these coordinates to express the particle's position and velocity vectors $\vec{r}$ and $\vec{v}$. Using its definition, we can express the projectile's angular momentum $\vec{L}$ as a function of time and then differentiate this expression to obtain $d\vec{L}/dt$. Finally, we can use the definition of the torque, relative to an origin located at the launch position, the gravitational force exerts on the projectile to express $\vec{\tau}$ and complete the demonstration that $d\vec{L}/dt = \vec{\tau}$.

Using its definition, express the angular momentum vector $\vec{L}$ of the projectile:

$$\vec{L} = \vec{r}\times m\vec{v} \qquad (1)$$

Using constant-acceleration equations, express the position coordinates of the projectile as a function of time:

$$x = v_{0x}t = \left(v_0\cos\theta\right)t$$

and

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_yt^2 = \left(v_0\sin\theta\right)t - \tfrac{1}{2}gt^2$$

Express the projectile's position vector $\vec{r}$:

$$\vec{r} = \left[\left(v_0\cos\theta\right)t\right]\hat{i} + \left[\left(v_0\sin\theta\right)t - \tfrac{1}{2}gt^2\right]\hat{j}$$

Using constant-acceleration equations, express the velocity of the projectile as a function of time:

$$v_x = v_{0x} = v_0\cos\theta$$

and

$$v_y = v_{0y} + a_yt = v_0\sin\theta - gt$$

Express the projectile's velocity vector $\vec{v}$:

$$\vec{v} = \left[v_0\cos\theta\right]\hat{i} + \left[v_0\sin\theta - gt\right]\hat{j}$$

Substituting in equation (1) and simplifying yields:

$$\vec{L} = \left\{\left[(V\cos\theta)t\right]\hat{i} + \left[(V\sin\theta)t - \tfrac{1}{2}gt^2\right]\hat{j}\right\} \times m\left\{\left[V\cos\theta\right]\hat{i} + \left[V\sin\theta - gt\right]\hat{j}\right\}$$
$$= \left(-\tfrac{1}{2}mgt^2V\cos\theta\right)\hat{k}$$

Differentiate $\vec{L}$ with respect to t to obtain:

$$\frac{d\vec{L}}{dt} = \frac{d}{dt}\left(-\tfrac{1}{2}mgt^2V\cos\theta\right)\hat{k} = \left(-mgtV\cos\theta\right)\hat{k} \quad (2)$$

Using its definition, express the torque acting on the projectile:

$$\vec{\tau} = \vec{r} \times (-mg)\hat{j} = \left[(v_0\cos\theta)t\right]\hat{i} + \left[(v_0\sin\theta)t - \tfrac{1}{2}gt^2\right]\hat{j} \times (-mg)\hat{j} = \left(-mgtV\cos\theta\right)\hat{k} \quad (3)$$

Comparing equations (2) and (3) we see that:

$$\boxed{\frac{d\vec{L}}{dt} = \vec{\tau}}$$

Conservation of Angular Momentum

48 • A planet moves in an elliptical orbit about the Sun, with the Sun at one focus of the ellipse, as in Figure 10-48. (*a*) What is the torque about the center of the Sun due to the gravitational force of attraction of the Sun on the planet? (*b*) At position A, the planet has an orbital radius r_1 and is moving with a speed v_1 perpendicular to the line from the sun to the planet. At position B, the planet has an orbital radius r_2 and is moving with speed v_2, again perpendicular to the line from the sun to the planet. What is the ratio of v_1 to v_2 in terms of r_1 and r_2?

Picture the Problem Let m represent the mass of the planet and apply the definition of torque to find the torque produced by the gravitational force of attraction. We can use Newton's second law of motion in the form $\vec{\tau} = d\vec{L}/dt$ to show that $\vec{L}$ is constant and apply conservation of angular momentum to the motion of the planet at points A and B.

(*a*) Express the torque produced by the gravitational force of attraction of the sun for the planet:

$\vec{\tau} = \vec{r} \times \vec{F} = \boxed{0}$ because $\vec{F}$ acts along the direction of $\vec{r}$.

(*b*) Because $\vec{\tau} = 0$:

$$\frac{d\vec{L}}{dt} = 0 \Rightarrow \vec{L} = \vec{r} \times m\vec{v} = \text{constant}$$

Noting that at points A and B $|\vec{r}\times\vec{v}| = rv$, express the relationship between the distances from the sun and the speeds of the planets:

$$r_1v_1 = r_2v_2 \Rightarrow \frac{v_1}{v_2} = \boxed{\frac{r_2}{r_1}}$$

49 •• **[SSM]** You stand on a frictionless platform that is rotating at an angular speed of 1.5 rev/s. Your arms are outstretched, and you hold a heavy weight in each hand. The moment of inertia of you, the extended weights, and the platform is 6.0 kg·m^2. When you pull the weights in toward your body, the moment of inertia decreases to 1.8 kg·m^2. (*a*) What is the resulting angular speed of the platform? (*b*) What is the change in kinetic energy of the system? (*c*) Where did this increase in energy come from?

Picture the Problem Let the system consist of you, the extended weights, and the platform. Because the net external torque acting on this system is zero, its angular momentum remains constant during the pulling in of the weights.

(*a*) Using conservation of angular momentum, relate the initial and final angular speeds of the system to its initial and final moments of inertia:

$$I_i\omega_i - I_f\omega_f = 0 \Rightarrow \omega_f = \frac{I_i}{I_f}\omega_i$$

Substitute numerical values and evaluate ω_f:

$$\omega_f = \frac{6.0\,\text{kg}\cdot\text{m}^2}{1.8\,\text{kg}\cdot\text{m}^2}(1.5\,\text{rev/s}) = \boxed{5.0\,\text{rev/s}}$$

(*b*) Express the change in the kinetic energy of the system:

$$\Delta K = K_f - K_i = \tfrac{1}{2}I_f\omega_f^2 - \tfrac{1}{2}I_i\omega_i^2$$

Substitute numerical values and evaluate ΔK:

$$\Delta K = \tfrac{1}{2}(1.8\,\text{kg}\cdot\text{m}^2)\left(5.0\frac{\text{rev}}{\text{s}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\right)^2 - \tfrac{1}{2}(6.0\,\text{kg}\cdot\text{m}^2)\left(1.5\frac{\text{rev}}{\text{s}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\right)^2$$
$$= \boxed{0.62\,\text{kJ}}$$

(*c*) Because no external agent does work on the system, the energy comes from your internal energy.

50 •• A small blob of putty of mass m falls from the ceiling and lands on the outer rim of a turntable of radius R and moment of inertia I_0 that is rotating freely with angular speed ω_0 about its vertical fixed-symmetry axis. (*a*) What is the post-collision angular speed of the turntable-putty system? (*b*) After several turns, the

blob flies off the edge of the turntable. What is the angular speed of the turntable after the blob's departure?

Picture the Problem Let the system consist of the blob of putty and the turntable. Because the net external torque acting on this system is zero, its angular momentum remains constant when the blob of putty falls onto the turntable.

(*a*) Using conservation of angular momentum, relate the initial and final angular speeds of the turntable to its initial and final moments of inertia and solve for ω_f:

$$I_0\omega_0 - I_f\omega_f = 0 \Rightarrow \omega_f = \frac{I_0}{I_f}\omega_0 \quad (1)$$

Express the final rotational inertia of the turntable-plus-blob:

$$I_f = I_0 + I_{blob} = I_0 + mR^2$$

Substitute for I_f in equation (1) and simplify to obtain:

$$\omega_f = \frac{I_0}{I_0 + mR^2}\omega_0 = \boxed{\frac{1}{1+\dfrac{mR^2}{I_0}}\omega_0}$$

(*b*) If the blob flies off tangentially to the turntable, its angular momentum doesn't change (with respect to an axis through the center of turntable). Because there is no external torque acting on the blob-turntable system, the total angular momentum of the system will remain constant and the angular momentum of the turntable will not change. The turntable will continue to spin at $\boxed{\omega' = \omega_f}$.

51 •• [SSM] A lazy Susan consists of a heavy plastic disk mounted on a frictionless bearing resting on a vertical shaft through its center. The cylinder has a radius R = 15 cm and mass M = 0.25 kg. A cockroach (mass m = 0.015 kg) is on the lazy Susan, at a distance of 8.0 cm from the center. Both the cockroach and the lazy Susan are initially at rest. The cockroach then walks along a circular path concentric with the center of the Lazy Susan at a constant distance of 8.0 cm from the axis of the shaft. If the speed of the cockroach with respect to the lazy Susan is 0.010 m/s, what is the speed of the cockroach with respect to the room?

Picture the Problem Because the net external torque acting on the lazy Susan-cockroach system is zero, the net angular momentum of the system is constant (equal to zero because the lazy Susan is initially at rest) and we can use conservation of angular momentum to find the angular velocity ω of the lazy Susan. The speed of the cockroach relative to the floor v_f is the difference between its speed with respect to the lazy Susan and the speed of the lazy Susan at the location of the cockroach with respect to the floor.

Relate the speed of the cockroach with respect to the floor v_f to the speed of the lazy Susan at the location of the cockroach:

$$v_f = v - \omega r \quad (1)$$

Use conservation of angular momentum to obtain:

$$L_{LS} - L_C = 0 \quad (2)$$

Express the angular momentum of the lazy Susan:

$$L_{LS} = I_{LS}\omega = \tfrac{1}{2}MR^2\omega$$

Express the angular momentum of the cockroach:

$$L_C = I_C\omega_C = mr^2\left(\frac{v}{r} - \omega\right)$$

Substitute for L_{LS} and L_C in equation (2) to obtain:

$$\tfrac{1}{2}MR^2\omega - mr^2\left(\frac{v}{r} - \omega\right) = 0$$

Solving for ω yields:

$$\omega = \frac{2mrv}{MR^2 + 2mr^2}$$

Substitute for ω in equation (1) to obtain:

$$v_f = v - \frac{2mr^2v}{MR^2 + 2mr^2}$$

Substitute numerical values and evaluate v_f:

$$v_f = 0.010\,\text{m/s} - \frac{2(0.015\,\text{kg})(0.080\,\text{m})^2(0.010\,\text{m/s})}{(0.25\,\text{m})(0.15\,\text{m})^2 + 2(0.015\,\text{kg})(0.080\,\text{m})^2} = \boxed{10\,\text{mm/s}}$$

Remarks: Because the moment of inertia of the lazy Susan is so much larger than the moment of inertia of the cockroach, after the cockroach begins moving, the angular speed of the lazy Susan is very small. Therefore, the speed of the cockroach relative to the floor is almost the same as the speed relative to the lazy Susan.

52 •• Two disks of identical mass but different radii (r and $2r$) are spinning on frictionless bearings at the same angular speed ω_0 but in opposite directions (Figure 10-49). The two disks are brought slowly together. The resulting frictional force between the surfaces eventually brings them to a common angular velocity. (a) What is the magnitude of that final angular velocity in terms of ω_0? (b) What is the change in rotational kinetic energy of the system? Explain.

Picture the Problem The net external torque acting on this system is zero and so we know that angular momentum is conserved as these disks are brought together. Let the numeral 1 refer to the disk to the left and the numeral 2 to the disk to the right. Let the angular momentum of the disk with the larger radius be positive.

(*a*) Using conservation of angular momentum, relate the initial angular speeds of the disks to their common final speed and to their moments of inertia:

$$I_i\omega_i = I_f\omega_f$$

or

$$I_1\omega_0 - I_2\omega_0 = (I_1 + I_2)\omega_f$$

Solving for ω_f yields:

$$\omega_f = \frac{I_1 - I_2}{I_1 + I_2}\omega_0 \qquad (1)$$

Express I_1 and I_2:

$$I_1 = \tfrac{1}{2}m(2r)^2 = 2mr^2$$

and

$$I_2 = \tfrac{1}{2}mr^2$$

Substitute for I_1 and I_2 in equation (1) and simplify to obtain:

$$\omega_f = \frac{2mr^2 - \frac{1}{2}mr^2}{2mr^2 + \frac{1}{2}mr^2}\omega_0 = \boxed{\tfrac{3}{5}\omega_0}$$

(*b*) The change in kinetic energy of the system is given by:

$$\Delta K = K_f - K_i \qquad (2)$$

The initial kinetic energy of the system is the sum of the kinetic energies of the two disks:

$$K_i = K_1 + K_2 = \tfrac{1}{2}I_1\omega_0^2 + \tfrac{1}{2}I_2\omega_0^2 = \tfrac{1}{2}(I_1 + I_2)\omega_0^2$$

Substituting for K_f and K_i in equation (2) yields:

$$\Delta K = \tfrac{1}{2}(I_1 + I_2)\omega_f^2 - \tfrac{1}{2}(I_1 + I_2)\omega_0^2$$

Substitute for ω_f from part (*a*) and simplify to obtain:

$$\Delta K = \tfrac{1}{2}(I_1 + I_2)\left(\tfrac{3}{5}\omega_0\right)^2 - \tfrac{1}{2}(I_1 + I_2)\omega_0^2 = -\tfrac{16}{25}\left[\tfrac{1}{2}(I_1 + I_2)\omega_0^2\right]$$

Noting that the quantity in brackets is K_i, substitute to obtain:

$$\Delta K = \boxed{-\tfrac{16}{25}K_i}$$

The frictional force between the surfaces is responsible for some of the initial kinetic energy being converted to thermal energy as the two disks come together.

53 •• A block of mass m sliding on a frictionless table is attached to a string that passes through a narrow hole through the center of the table. The block is sliding with speed v_0 in a circle of radius r_0. Find (*a*) the angular momentum of the block, (*b*) the kinetic energy of the block, and (*c*) the tension in the string. (*d*) A student under the table now slowly pulls the string downward. How much work is required to reduce the radius of the circle from r_0 to $r_0/2$?

Picture the Problem (*a*) and (*b*) We can express the angular momentum and kinetic energy of the block directly from their definitions. (*c*) The tension in the string provides the centripetal force required for the uniform circular motion and can be expressed using Newton's second law. (*d*) Finally, we can use the work-kinetic energy theorem to express the work required to reduce the radius of the circle by a factor of two.

(*a*) Express the initial angular momentum of the block:

$$L_0 = \boxed{r_0 m v_0}$$

(*b*) Express the initial kinetic energy of the block:

$$K_0 = \boxed{\tfrac{1}{2} m v_0^2}$$

(*c*) Using Newton's second law, relate the tension in the string to the centripetal force required for the circular motion:

$$T = F_c = \boxed{m\frac{v_0^2}{r_0}}$$

(*d*) Use the work-kinetic energy theorem to relate the required work to the change in the kinetic energy of the block:

$$W = \Delta K = K_f - K_0 = \frac{L_f^2}{2I_f} - \frac{L_0^2}{2I_0}$$

$$= \frac{L_0^2}{2I_f} - \frac{L_0^2}{2I_0} = \frac{L_0^2}{2}\left(\frac{1}{I_f} - \frac{1}{I_0}\right)$$

$$= \frac{L_0^2}{2}\left(\frac{1}{m\left(\frac{1}{2}r_0\right)^2} - \frac{1}{mr_0^2}\right)$$

$$= \frac{L_0^2}{2}\left(\frac{4}{mr_0^2} - \frac{1}{mr_0^2}\right) = \frac{L_0^2}{2}\left(\frac{3}{mr_0^2}\right)$$

Substituting for L_0 from Part (*a*) and simplifying gives:

$$W = \frac{(r_0 m v_0)^2}{2}\left(\frac{3}{mr_0^2}\right) = \boxed{\tfrac{3}{2} m v_0^2}$$

54 ••• A 0.20-kg point mass moving on a frictionless horizontal surface is attached to a rubber band whose other end is fixed at point P. The rubber band exerts a force whose magnitude is $F = bx$, where x is the length of the rubber band

and b is an unknown constant. The rubber band force points inward towards P. The mass moves along the dotted line in Figure 10-50. When it passes point A, its velocity is 4.0 m/s, directed as shown. The distance AP is 0.60 m and BP is 1.0 m. (*a*) Find the speed of the mass at points B and C. (*b*) Find b.

Picture the Problem Because the force exerted by the rubber band is parallel to the position vector of the point mass, the net external torque acting on it is zero and we can use the conservation of angular momentum to determine the speeds of the ball at points B and C. We'll use mechanical energy conservation to find b by relating the kinetic and elastic potential energies at A and B.

(*a*) Use conservation of momentum to relate the angular momenta at points A, B and C:

$$L_A = L_B = L_C$$

or

$$mv_A r_A = mv_B r_B = mv_C r_C \qquad (1)$$

Solve for v_B in terms of v_A:

$$v_B = v_A \frac{r_A}{r_B}$$

Substitute numerical values and evaluate v_B:

$$v_B = (4.0\,\text{m/s})\frac{0.60\,\text{m}}{1.0\,\text{m}} = \boxed{2.4\,\text{m/s}}$$

Solve equation (1) for v_C in terms of v_A:

$$v_C = v_A \frac{r_A}{r_C}$$

Substitute numerical values and evaluate v_C:

$$v_C = (4.0\,\text{m/s})\frac{0.60\,\text{m}}{0.60\,\text{m}} = \boxed{4.0\,\text{m/s}}$$

(*b*) Use conservation of mechanical energy between points A and B to relate the kinetic energy of the point mass and the energy stored in the stretched rubber band:

$$\Delta E = E_A - E_B = 0$$

or

$$\tfrac{1}{2}mv_A^2 + \tfrac{1}{2}br_A^2 - \tfrac{1}{2}mv_B^2 - \tfrac{1}{2}br_B^2 = 0$$

Solving for b yields:

$$b = \frac{m\left(v_B^2 - v_A^2\right)}{r_A^2 - r_B^2}$$

Substitute numerical values and evaluate b:

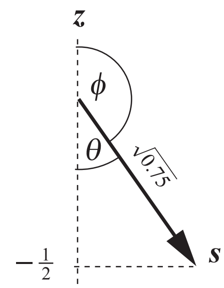
$$b = \frac{(0.20\,\text{kg})\left[(2.4\,\text{m/s})^2 - (4.0\,\text{m/s})^2\right]}{(0.60\,\text{m})^2 - (1.0\,\text{m})^2}$$

$$= \boxed{3\,\text{N/m}}$$

*Quantization of Angular Momentum

55 •• **[SSM]** The z component of the spin of an electron is $-\frac{1}{2}\hbar$, but the magnitude of the spin vector is $\sqrt{0.75}\hbar$. What is the angle between the electron's spin angular momentum vector and the positive z-axis?

Picture the Problem The electron's spin angular momentum vector is related to its z component as shown in the diagram. The angle between $\vec{s}$ and the $+z$-axis is ϕ.



Express ϕ in terms of θ to obtain: $\phi = 180° - \theta$

Using trigonometry, relate the magnitude of $\vec{s}$ to its $-z$ component:

$$\theta = \cos^{-1}\left(\frac{\frac{1}{2}\hbar}{\sqrt{0.75}\hbar}\right)$$

Substitute for θ in the expression for ϕ to obtain:

$$\theta = 180° - \cos^{-1}\left(\frac{\frac{1}{2}\hbar}{\sqrt{0.75}\hbar}\right) = \boxed{125°}$$

56 •• Show that the energy difference between one rotational state of a molecule and the next higher state is proportional to $\ell + 1$.

Picture the Problem Equation 10-29*a* describes the quantization of rotational energy. We can show that the energy difference between a given state and the next higher state is proportional to $\ell + 1$ by using Equation 10-27*a* to express the energy difference.

From Equation 10-29*a* we have: $K_\ell = \ell(\ell + 1)E_{0r}$

Using this equation, express the difference between one rotational state and the next higher state:

$$\Delta E = (\ell + 1)(\ell + 2)E_{0r} - \ell(\ell + 1)E_{0r}$$
$$= \boxed{2(\ell + 1)E_{0r}}$$

57 •• **[SSM]** You work in a bio-chemical research lab, where you are investigating the rotational energy levels of the HBr molecule. After consulting the periodic chart, you know that the mass of the bromine atom is 80 times that of the hydrogen atom. Consequently, in calculating the rotational motion of the molecule, you assume, to a good approximation, that the Br nucleus remains stationary as the H atom (mass 1.67×10^{-27} kg) revolves around it. You also know

that the separation between the H atom and bromine nucleus is 0.144 nm. Calculate (*a*) the moment of inertia of the HBr molecule about the bromine nucleus, and (*b*) the rotational energies for the bromine nucleus's *ground state* (lowest energy) $\ell = 0$, and the next two states of higher energy (called the first and second *excited states*) described by $\ell = 1$, and $\ell = 2$.

Picture the Problem The rotational energies of HBr molecule are related to ℓ and E_{0r} according to $K_\ell = \ell(\ell+1)E_{0r}$ where $E_{0r} = \hbar^2/2I$.

(*a*) Neglecting the motion of the bromine molecule:

$$I_{HBr} \approx m_p r^2 = m_H r^2$$

Substitute numerical values and evaluate I_{HBr}:

$$I_{HBr} \approx (1.67\times10^{-27}\ \text{kg})(0.144\times10^{-9}\ \text{m})^2 = 3.463\times10^{-47}\ \text{kg}\cdot\text{m}^2 = \boxed{3.46\times10^{-47}\ \text{kg}\cdot\text{m}^2}$$

(*b*) Relate the rotational energies to ℓ and E_{0r}:

$$K_\ell = \ell(\ell+1)E_{0r} \text{ where } E_{0r} = \frac{\hbar^2}{2I_{HBr}}$$

Substitute numerical values and evaluate E_{0r}:

$$E_{0r} = \frac{\hbar^2}{2I} = \frac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2}{2(3.463\times10^{-47}\ \text{kg}\cdot\text{m}^2)} = 1.607\times10^{-22}\ \text{J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}} = 1.003\,\text{meV}$$

Evaluate E_0 to obtain:

$$E_0 = K_0 = \boxed{1.00\,\text{meV}}$$

Evaluate E_1 to obtain:

$$E_1 = K_1 = (1+1)(1.003\,\text{meV}) = \boxed{2.01\,\text{meV}}$$

Evaluate E_2 to obtain:

$$E_2 = K_2 = 2(2+1)(1.003\,\text{meV}) = \boxed{6.02\,\text{meV}}$$

58 ••• The equilibrium separation between the nuclei of the nitrogen molecule (N_2) is 0.110 nm and the mass of each nitrogen nucleus is 14.0 u, where u = 1.66×10^{-27} kg. For rotational energies, the total energy is due to rotational kinetic energy. (*a*) Approximate the nitrogen molecule as a rigid dumbbell of two equal point masses and calculate the moment of inertia about its center of mass.

(*b*) Find the energy E_ℓ of the lowest three energy levels using $E_\ell = K_\ell = \ell(\ell+1)\hbar^2/(2I)$. (*c*) Molecules emit a particle (or *quantum*) of light called a *photon* when they make a *transition* from a higher energy state to a lower one. Determine the energy of a photon emitted when a nitrogen molecule drops from the $\ell = 2$ to the $\ell = 1$ state. Visible light photons each have between 2 and 3 eV of energy. Are these photons in the visible region?

Picture the Problem We can use the definition of the moment of inertia of point particles to calculate the rotational inertia of the nitrogen molecule. The rotational energies of nitrogen molecule are related to ℓ and E_{0r} according to $E_\ell = K_\ell = \ell(\ell+1)E_{0r}$ where $E_{0r} = \hbar^2/2I$.

(*a*) Using a rigid dumbbell model, express and evaluate the moment of inertia of the nitrogen molecule about its center of mass:

$$I_{N_2} = \sum_i m_i r_i^2 = m_N r^2 + m_N r^2 = 2m_N r^2$$

Substitute numerical values and evaluate I_{N_2}:

$$I_{N_2} = 2(14)(1.66\times10^{-27}\text{ kg})\left(\frac{0.110\text{ nm}}{2}\right)^2 = 1.406\times10^{-46}\text{ kg}\cdot\text{m}^2 = \boxed{1.41\times10^{-46}\text{ kg}\cdot\text{m}^2}$$

(*b*) Relate the rotational energies to ℓ and E_{0r}:

$$E_\ell = K_\ell = \ell(\ell+1)E_{0r}$$

where

$$E_{0r} = \frac{\hbar^2}{2I_{N_2}}$$

Substitute numerical values and evaluate E_{0r}:

$$E_{0r} = \frac{(1.055\times10^{-34}\text{ J}\cdot\text{s})^2}{2(1.406\times10^{-46}\text{ kg}\cdot\text{m}^2)} = 3.958\times10^{-23}\text{ J}\times\frac{1\text{eV}}{1.60\times10^{-19}\text{ J}} = 0.2474\text{ meV}$$

Evaluate E_0 to obtain:

$$E_0 = \boxed{0.247\text{ meV}}$$

Evaluate E_1 to obtain:

$$E_1 = (1+1)(0.2474\text{ meV}) = \boxed{0.495\text{ meV}}$$

Evaluate E_2 to obtain:

$$E_2 = 2(2+1)(0.2474\,\text{meV}) = \boxed{1.48\,\text{meV}}$$

(c) The energy of a photon emitted when a nitrogen molecule drops from the $\ell = 2$ to the $\ell = 1$ state is:

$$\Delta E_{\ell=2\to\ell=1} = E_2 - E_1 = 1.48\,\text{meV} - 0.495\,\text{meV} = \boxed{0.99\,\text{meV}}$$

No. This energy is too low to produce radiation in the visible portion of the spectrum.

59 ••• Consider a *transition* from a lower energy state to a higher one. That is, the absorption of a quantum of energy resulting in an increase in the rotational energy of an N_2 molecule (see Problem 64). Suppose such a molecule, initially in its ground rotational state, was exposed to photons each with energy equal to the three times the energy of its first excited state. (a) Would the molecule be able to absorb this photon energy? Explain why or why not and if it can, determine the energy level to which it goes. (b) To make a transition from its ground state to its second excited state requires how many times the energy of the first excited state?

Picture the Problem The rotational energies of a nitrogen molecule depend on the quantum number ℓ according to $E_\ell = L^2/2I = \ell(\ell+1)\hbar^2/2I$.

(a) No. None of the allowed values of E_ℓ are equal to $E_{0\text{r}}$.

(b) The upward transition from the ground state to the second excited state requires energy given by:

$$\Delta E_{\ell=0\to\ell=2} = E_2 - E_0$$

Set this energy difference equal to a constant n times the energy of the 1st excited state:

$$E_2 - E_0 = nE_1 \Rightarrow n = \frac{E_2 - E_0}{E_1}$$

Substitute numerical values and evaluate n:

$$n = \frac{2(2+1)E_{0\text{r}} - E_{0\text{r}}}{(1+1)E_{0\text{r}}} = \boxed{2.5}$$

Collisions with Rotations

60 •• A 16.0-kg, 2.40-m-long rod is supported at its midpoint on a knife edge. A 3.20-kg ball of clay drops from rest from a height of 1.20 m and makes a perfectly inelastic collision with the rod 0.90 m from the point of support (Figure 10-51). Find the angular momentum of the rod and clay system about the point of support immediately after the inelastic collision.

Picture the Problem Let the zero of gravitational potential energy be at the elevation of the rod. Because the net external torque acting on this system is zero, we know that angular momentum is conserved in the collision. We'll use the definition of angular momentum to express the angular momentum just after the collision and conservation of mechanical energy to determine the speed of the ball just before it makes its perfectly inelastic collision with the rod.

Use conservation of angular momentum to relate the angular momentum before the collision to the angular momentum just after the perfectly inelastic collision:

$$L_f = L_i = mvr \qquad (1)$$

Use conservation of mechanical energy to relate the kinetic energy of the ball just before impact to its initial potential energy:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_i = U_f = 0$,

$$K_f - U_i = 0$$

Letting h represent the distance the ball falls, substitute for K_f and U_i to obtain:

$$\tfrac{1}{2}mv^2 - mgh = 0 \Rightarrow v = \sqrt{2gh}$$

Substituting for v in equation (1) yields:

$$L_f = mr\sqrt{2gh}$$

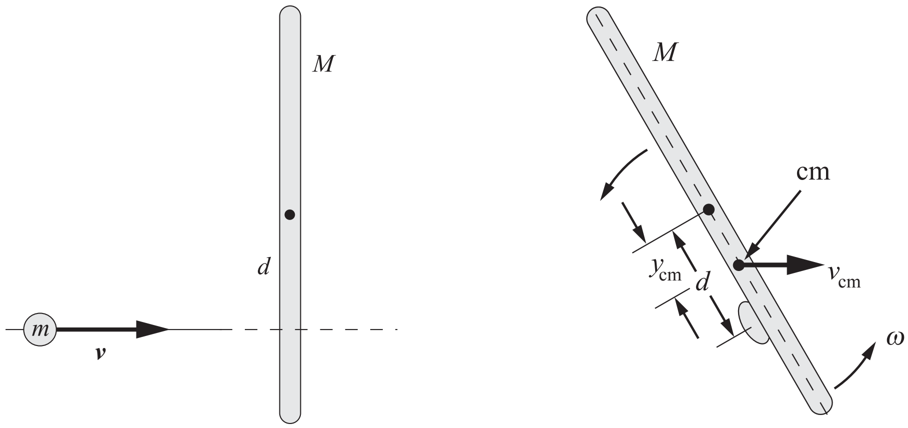
Substitute numerical values and evaluate L_f:

$$L_f = (3.20\,\text{kg})(0.90\,\text{m})\sqrt{2(9.81\,\text{m/s}^2)(1.20\,\text{m})} = \boxed{14\,\text{J}\cdot\text{s}}$$

61 •• [SSM] Figure 10-52 shows a thin uniform bar of length L and mass M and a small blob of putty of mass m. The system is supported by a frictionless horizontal surface. The putty moves to the right with velocity $\vec{v}$, strikes the bar at a distance d from the center of the bar, and sticks to the bar at the point of contact. Obtain expressions for the velocity of the system's center of mass and for the angular speed following the collision.

Picture the Problem The velocity of the center of mass of the bar-blob system does not change during the collision and so we can calculate it before the collision using its definition. Because there are no external forces or torques acting on the bar-blob system, both linear and angular momentum are conserved in the collision. Let the direction the blob of putty is moving initially be the $+x$ direction. Let lower-case letters refer to the blob of putty and upper-case letters refer to the bar.

The diagram to the left shows the blob of putty approaching the bar and the diagram to the right shows the bar-blob system rotating about its center of mass and translating after the perfectly inelastic collision.



The velocity of the center of mass before the collision is given by:

$$(M+m)\vec{v}_{\text{cm}} = m\vec{v} + M\vec{V}$$

or, because $\vec{V} = 0$,

$$\vec{v}_{\text{cm}} = \boxed{\frac{m}{M+m}\vec{v}}$$

Using its definition, express the location of the center of mass relative to the center of the bar:

$$(M+m)y_{\text{cm}} = md \Rightarrow y_{\text{cm}} = \frac{md}{M+m}$$

below the center of the bar.

Express the angular momentum, relative to the center of mass, of the bar-blob system:

$$L_{\text{cm}} = I_{\text{cm}}\omega \Rightarrow \omega = \frac{L_{\text{cm}}}{I_{\text{cm}}} \qquad (1)$$

Express the angular momentum about the center of mass:

$$L_{\text{cm}} = mv(d - y_{\text{cm}}) = mv\left(d - \frac{md}{M+m}\right) = \frac{mMvd}{M+m}$$

Using the parallel axis theorem, express the moment of inertia of the system relative to its center of mass:

$$I_{\text{cm}} = \tfrac{1}{12}ML^2 + My_{\text{cm}}^2 + m(d - y_{\text{cm}})^2$$

Substitute for y_{cm} and simplify to obtain:

$$I_{\text{cm}} = \tfrac{1}{12}ML^2 + M\left(\frac{md}{M+m}\right)^2 + m\left(d - \frac{md}{M+m}\right)^2 = \tfrac{1}{12}ML^2 + \frac{mMd^2}{M+m}$$

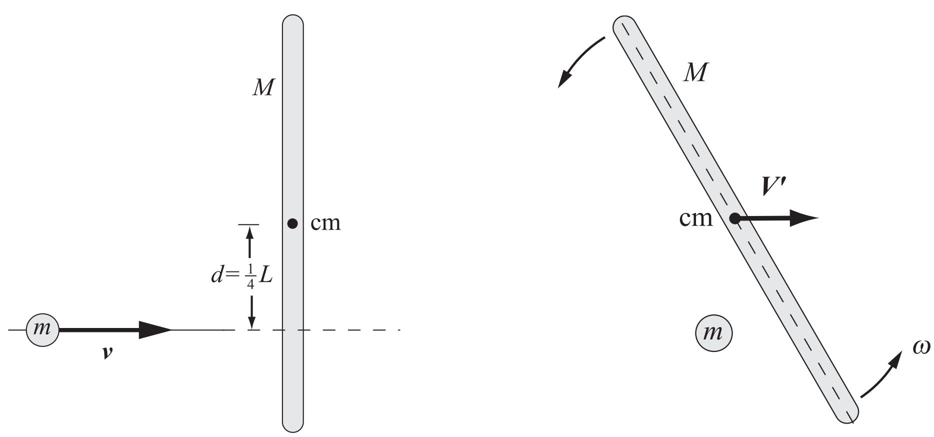
Substitute for I_{cm} and L_{cm} in equation (1) and simplify to obtain:

$$\omega = \boxed{\frac{mMvd}{\frac{1}{12}ML^2(M+m)+Mmd^2}}$$

Remarks: You can verify the expression for I_{cm} by letting $m \to 0$ to obtain $I_{cm} = \frac{1}{12}ML^2$ and letting $M \to 0$ to obtain $I_{cm} = 0$.

62 •• Figure 10-52 shows a thin uniform bar whose length is L and mass is M and a compact hard sphere whose mass is m. The system is supported by a frictionless horizontal surface. The sphere moves to the right with velocity $\vec{v}$, strikes the bar at a distance $\frac{1}{4}L$ from the center of the bar. The collision is elastic, and following the collision the sphere is at rest. Find the value of the ratio m/M.

Picture the Problem Because there are no external forces or torques acting on the bar-sphere system, both linear and angular momentum are conserved in the collision. Kinetic energy is also conserved in the elastic collision of the hard sphere with the bar. Let the direction the sphere is moving initially be the $+x$ direction Let lower-case letters refer to the compact hard sphere and upper-case characters refer to the bar. Let unprimed characters refer to before the collision and primed characters to after the collision. The diagram to the left shows the path of the sphere before its collision with the bar and the diagram to the right shows the sphere at rest after the collision and the bar rotating about its center of mass and translating to the right.



Apply conservation of linear momentum to the collision to obtain:

$$mv = 0 + MV' \Rightarrow V' = \frac{m}{M}v \qquad (1)$$

Apply conservation of angular momentum to the collision to obtain:

$$mvd = 0 + I_{cm}\omega \qquad (2)$$

Apply conservation of mechanical energy to the elastic collision to obtain:

$$\tfrac{1}{2}mv^2 = 0 + \tfrac{1}{2}MV'^2 + \tfrac{1}{2}I_{\text{cm}}\omega^2 \quad (3)$$

Use Table 9-1 to find the moment of inertia of a thin bar about an axis through its center:

$$I_{\text{cm}} = \tfrac{1}{12}ML^2$$

Substitute for I_{cm} in equation (2) and simplify to obtain:

$$mvd = \tfrac{1}{12}ML^2\omega \Rightarrow \omega = \left(\frac{12vd}{L^2}\right)\frac{m}{M}$$

Substitute for I_{cm} and V' in equation (3) and simplify to obtain:

$$mv^2 = M\left(\frac{m}{M}\right)^2 v^2 + \tfrac{1}{12}ML^2\omega^2$$

Substituting for ω yields:

$$mv^2 = M\left(\frac{m}{M}\right)^2 v^2 + \tfrac{1}{12}ML^2\left[\left(\frac{12vd}{L^2}\right)\frac{m}{M}\right]^2$$

Solve this equation for $\frac{m}{M}$ to obtain:

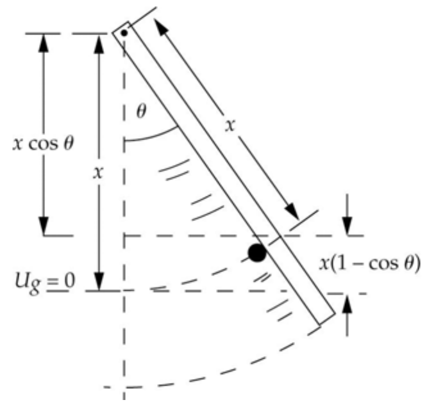
$$\frac{m}{M} = \frac{1}{1 + 12\left(\frac{d}{L}\right)^2}$$

Because $d = L/4$:

$$\frac{m}{M} = \frac{1}{1 + 12\left(\frac{1}{4}\right)^2} = \boxed{\frac{4}{7}}$$

63 •• Figure 10-53 shows a uniform rod whose length is L and whose mass is M pivoted at the top. The rod, which is initially at rest, is struck by a particle whose mass is m at a point $x = 0.8L$ below the pivot. Assume that the particle sticks to the rod. What must be the speed v of the particle so that following the collision the maximum angle between the rod and the vertical is 90°?

Picture the Problem Let the zero of gravitational potential energy be a distance x below the pivot and ignore friction between the rod and the pivot. Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision. We can also use conservation of mechanical energy to relate the initial kinetic energy of the system after the collision to its potential energy at the top of its swing.



Using conservation of mechanical energy, relate the rotational kinetic energy of the system just after the collision to its gravitational potential energy when it has swung through an angle θ:

$\Delta K + \Delta U = 0$

or, because $K_f = U_i = 0$,

$-K_i + U_f = 0$

Substitute for K_i and U_f to obtain:

$$-\tfrac{1}{2}I\omega^2 + \left(Mg\frac{L}{2} + mgx\right)(1-\cos\theta) = 0 \quad (1)$$

Applying conservation of angular momentum to the collision gives:

$$\Delta L = L_f - L_i = 0 \quad (2)$$

The moment of inertia of the system about the pivot is given by:

$$I_f = m(0.8L)^2 + \tfrac{1}{3}ML^2 \quad (3)$$

Substituting for I_f and I_i in equation (2) yields:

$$\left[\tfrac{1}{3}ML^2 + (0.8L)^2 m\right]\omega - 0.8Lmv = 0$$

Solving for ω yields:

$$\omega = \frac{0.8Lmv}{\tfrac{1}{3}ML^2 + 0.64mL^2} \quad (4)$$

Substitute equations (3) and (4) in equation (1) and simplify to obtain:

$$\frac{0.32(Lmv)^2}{\tfrac{1}{3}ML^2 + 0.64mL^2} - \left(Mg\frac{L}{2} + mg(0.8L)\right)(1-\cos\theta) = 0$$

Solving for v gives:

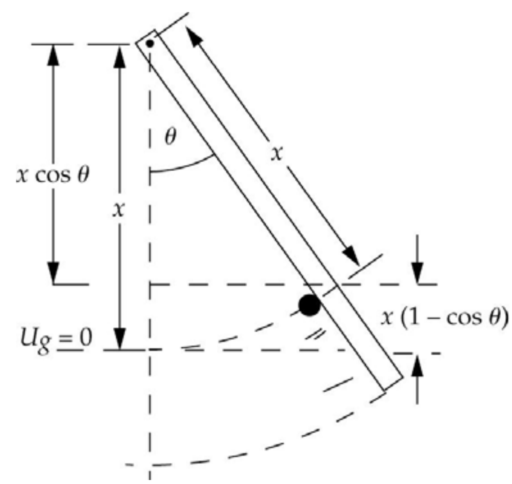
$$v = \sqrt{\frac{(0.5M + 0.8m)\left(\frac{1}{3}ML^2 + 0.64mL^2\right)g(1 - \cos\theta)}{0.32Lm^2}}$$

Evaluate v for $\theta = 90°$ to obtain:

$$\boxed{v = \sqrt{\frac{(0.5M + 0.8m)\left(\frac{1}{3}ML^2 + 0.64mL^2\right)g}{0.32Lm^2}}}$$

64 •• If, for the system of Problem 63, L = 1.2 m, M = 0.80 kg, m = 0.30 kg, and the maximum angle between the rod and the vertical following the collision is 60°, find the speed of the particle before impact.

Picture the Problem Let the zero of gravitational potential energy be a distance x below the pivot and ignore friction between the rod and pivot. Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision. We can also use conservation of mechanical energy to relate the initial kinetic energy of the system after the collision to its potential energy at the top of its swing.



Using conservation of mechanical energy, relate the rotational kinetic energy of the system just after the collision to its gravitational potential energy when it has swung through an angle θ:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f to obtain:

$$-\tfrac{1}{2}I\omega^2 + \left(Mg\frac{L}{2} + mgx\right)(1 - \cos\theta) = 0 \qquad (1)$$

Apply conservation of momentum to the collision:

$$\Delta L = L_f - L_i = 0 \qquad (2)$$

The moment of inertia of the system about the pivot is:

$$I = m(0.80L)^2 + \tfrac{1}{3}ML^2 = \left(0.64m + \tfrac{1}{3}M\right)L^2$$

Substituting for L_f and L_i in equation (2) gives:

$$\left(\tfrac{1}{3}M + 0.64m\right)L^2\omega - 0.80Lmv = 0$$

Solving for ω yields:

$$\omega = \frac{0.80Lmv}{\tfrac{1}{2}ML^2 + 0.64mL^2}$$

Substitute for ω in equation (1) and simplify to obtain:

$$-\frac{0.32(Lmv)^2}{I} + \left(Mg\frac{L}{2} + 0.80Lmg\right)(1-\cos\theta) = 0$$

Solving for v yields:

$$v = \sqrt{\frac{g(0.50M + 0.80m)(1-\cos\theta)I}{0.32Lm^2}}$$

Substitute numerical values and evaluate I:

$$I = \left[0.64(0.30\,\text{kg}) + \tfrac{1}{3}(0.80\,\text{kg})\right](1.2\,\text{m})^2 = 0.660\,\text{kg}\cdot\text{m}^2$$

Substitute numerical values and evaluate v for $\theta = 60°$ to obtain:

$$v = \sqrt{\frac{(9.81\,\text{m/s}^2)[0.50(0.80\,\text{kg}) + (0.80)(0.30\,\text{kg})](0.50)(0.660\,\text{kg}\cdot\text{m}^2)}{0.32(1.2\,\text{m})(0.30\,\text{kg})^2}} = \boxed{7.7\,\text{m/s}}$$

65 •• A uniform rod is resting on a frictionless table when it is suddenly struck at one end by a sharp horizontal blow in a direction perpendicular to the rod. The mass of the rod is M and the magnitude of the impulse applied by the blow is J. Immediately after the rod is struck, (*a*) what is the velocity of the center of mass of the rod, (*b*) what is the velocity of the end that is struck, (*c*) and what is the velocity of the other end of the rod? (*d*) Is there a point on the rod that remains motionless?

Picture the Problem Let the length of the uniform stick be ℓ. We can use the impulse-change in momentum theorem to express the velocity of the center of mass of the stick. By expressing the velocity V of the end of the stick in terms of the velocity of the center of mass and applying the angular impulse-change in angular momentum theorem we can find the angular velocity of the stick and, hence, the velocity of the end of the stick.

(*a*) Apply the impulse-change in momentum theorem to obtain:

$$J = \Delta p = p - p_0 = p$$

or, because $p_0 = 0$ and $p = Mv_{cm}$,

$$J = Mv_{cm} \Rightarrow v_{cm} = \boxed{\frac{J}{M}}$$

(*b*) Relate the velocity V of the end of the stick to the velocity of the center of mass v_{cm}:

$$V = v_{cm} + v_{\text{rel to cm}} = v_{cm} + \omega\left(\tfrac{1}{2}\ell\right) \quad (1)$$

Relate the angular impulse to the change in the angular momentum of the stick:

$$J\left(\tfrac{1}{2}\ell\right) = \Delta L = L - L_0 = I_{cm}\omega$$

or, because $L_0 = 0$,

$$J\left(\tfrac{1}{2}\ell\right) = I_{cm}\omega \quad (2)$$

Refer to Table 9-1 to find the moment of inertia of the stick with respect to its center of mass:

$$I_{cm} = \tfrac{1}{12}M\ell^2$$

Substitute for I_{cm} in equation (2) to obtain:

$$J\left(\tfrac{1}{2}\ell\right) = \tfrac{1}{12}M\ell^2\omega \Rightarrow \omega = \frac{6J}{M\ell}$$

Substituting for ω in equation (1) yields:

$$V = \frac{J}{M} + \left(\frac{6J}{M\ell}\right)\frac{\ell}{2} = \boxed{\frac{4J}{M}}$$

(*c*) Relate the velocity V' of the other end of the stick to the velocity of the center of mass v_{cm}:

$$V = v_{cm} - v_{\text{rel to cm}} = v_{cm} - \omega\left(\tfrac{1}{2}\ell\right)$$
$$= \frac{J}{M} - \left(\frac{6J}{M\ell}\right)\frac{\ell}{2} = \boxed{-\frac{2J}{M}}$$

(*d*) Yes, one point remains motionless, but only for a very brief time.

66 •• A projectile of mass m_p is traveling at a constant velocity $\vec{v}_0$ toward a stationary disk of mass M and radius R that is free to rotate about its axis O (Figure 10-54). Before impact, the projectile is traveling along a line displaced a distance b below the axis. The projectile strikes the disk and sticks to point B. Model the projectile as a point mass. (*a*) Before impact, what is the total angular momentum L_0 of the disk-projectile system about the axis? Answer the following questions in terms of the symbols given at the start of this problem. (*b*) What is

the angular speed ω of the disk-projectile system just after the impact? (*c*) What is the kinetic energy of the disk-projectile system after impact? (*d*) How much mechanical energy is lost in this collision?

Picture the Problem Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision.

(*a*) Use its definition to express the total angular momentum of the disk and projectile just before impact:

$$L_0 = \boxed{m_\mathrm{p} v_0 b}$$

(*b*) Use conservation of angular momentum to relate the angular momenta just before and just after the collision:

$$L_0 = L = I\omega \Rightarrow \omega = \frac{L_0}{I}$$

The moment of inertia of the disk-projectile after the impact is:

$$I = \tfrac{1}{2}MR^2 + m_\mathrm{p}R^2 = \tfrac{1}{2}\left(M + 2m_\mathrm{p}\right)R^2$$

Substitute for I in the expression for ω to obtain:

$$\omega = \boxed{\frac{2m_\mathrm{p} v_0 b}{\left(M + 2m_\mathrm{p}\right)R^2}}$$

(*c*) Express the kinetic energy of the system after impact in terms of its angular momentum:

$$K_\mathrm{f} = \frac{L^2}{2I} = \frac{\left(m_\mathrm{p} v_0 b\right)^2}{2\left[\tfrac{1}{2}\left(M + 2m_\mathrm{p}\right)R^2\right]}$$

$$= \boxed{\frac{\left(m_\mathrm{p} v_0 b\right)^2}{\left(M + 2m_\mathrm{p}\right)R^2}}$$

(*d*) Express the difference between the initial and final kinetic energies, substitute, and simplify to obtain:

$$\Delta E = K_\mathrm{i} - K_\mathrm{f}$$

$$= \tfrac{1}{2}m_\mathrm{p} v_0^2 - \frac{\left(m_\mathrm{p} v_0 b\right)^2}{\left(M + 2m_\mathrm{p}\right)R^2}$$

$$= \boxed{\tfrac{1}{2}m_\mathrm{p} v_0^2 \left[1 - \frac{2m_\mathrm{p} b^2}{\left(M + 2m_\mathrm{p}\right)R^2}\right]}$$

67 •• [SSM] A uniform rod of length L_1 and mass M equal to 0.75 kg is attached to a hinge of negligible mass at one end and is free to rotate in the vertical plane (Figure 10-55). The rod is released from rest in the position shown. A particle of mass m = 0.50 kg is supported by a thin string of length L_2 from the hinge. The particle sticks to the rod on contact. What should the ratio L_2/L_1 be so that θ_{max} = 60° after the collision?

Picture the Problem Assume that there is no friction between the rod and the hinge. Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision. The rod, on its downward swing, acquires rotational kinetic energy. Angular momentum is conserved in the perfectly inelastic collision with the particle and the rotational kinetic of the after-collision system is then transformed into gravitational potential energy as the rod-plus-particle swing upward. Let the zero of gravitational potential energy be at a distance L_1 below the pivot and use both angular momentum and mechanical energy conservation to relate the distances L_1 and L_2 and the masses M and m.

Use conservation of energy to relate the initial and final potential energy of the rod to its rotational kinetic energy just before it collides with the particle:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_i = 0$,

$$K_f + U_f - U_i = 0$$

Substitute for K_f, U_f, and U_i to obtain:

$$\tfrac{1}{2}\left(\tfrac{1}{3}ML_1^2\right)\omega^2 + Mg\frac{L_1}{2} - MgL_1 = 0$$

Solving for ω yields:

$$\omega = \sqrt{\frac{3g}{L_1}}$$

Letting ω' represent the angular speed of the rod-and-particle system just after impact, use conservation of angular momentum to relate the angular momenta before and after the collision:

$$\Delta L = L_f - L_i = 0$$

or

$$\left(\tfrac{1}{3}ML_1^2 + mL_2^2\right)\omega' - \left(\tfrac{1}{3}ML_1^2\right)\omega = 0$$

Solve for ω' to obtain:

$$\omega' = \frac{\tfrac{1}{3}ML_1^2}{\tfrac{1}{3}ML_1^2 + mL_2^2}\omega$$

Use conservation of energy to relate the rotational kinetic energy of the rod-plus-particle just after their collision to their potential energy when they have swung through an angle θ_{max}:

$$K_f - K_i + U_f - U_i = 0$$

Because $K_f = 0$:

$$-\tfrac{1}{2}I\omega'^2 + Mg\left(\tfrac{1}{2}L_1\right)\left(1-\cos\theta_{max}\right) + mgL_2\left(1-\cos\theta_{max}\right) = 0 \qquad (1)$$

Express the moment of inertia of the system with respect to the pivot:

$$I = \tfrac{1}{3}ML_1^2 + mL_2^2$$

Substitute for θ_{max}, I and ω' in equation (1):

$$\frac{3\dfrac{g}{L_1}\left(\tfrac{1}{3}ML_1^2\right)^2}{\tfrac{1}{3}ML_1^2 + mL_2^2} = Mg\left(\tfrac{1}{2}L_1\right) + mgL_2$$

Simplify to obtain:

$$L_1^3 = 2\frac{m}{M}L_1^2L_2 + 3\frac{m}{M}L_2^2L_1 + 6\frac{m}{M}L_2^3$$

Dividing both sides of the equation by L_1^3 yields:

$$1 = 2\left(\frac{m}{M}\right)\left(\frac{L_2}{L_1}\right) + 3\left(\frac{m}{M}\right)\left(\frac{L_2}{L_1}\right)^2 + 6\left(\frac{m}{M}\right)^2\left(\frac{L_2}{L_1}\right)^3$$

Let $\alpha = m/M$ and $\beta = L_2/L_1$ to obtain:

$$6\alpha^2\beta^3 + 3\alpha\beta^2 + 2\alpha\beta - 1 = 0$$

Substitute for α and simplify to obtain the cubic equation in β:

$$8\beta^3 + 6\beta^2 + 4\beta - 3 = 0$$

Use the solver function of your calculator to find the only real value of β:

$$\beta = \boxed{0.39}$$

68 •• A uniform rod that has a length L_1 equal to 1.2 m and a mass M equal to 2.0 kg is supported by a hinge at one end and is free to rotate in the vertical plane (Figure 10-55). The rod is released from rest in the position shown. A particle whose mass is m is supported by a thin string that has a length L_2 equal to 0.80 m from the hinge. The particle sticks to the rod on contact, and after the collision the rod continues to rotate until $\theta_{max} = 37°$. (*a*) Find m. (*b*) How much energy is dissipated during the collision?

Picture the Problem Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision. The rod, on its downward swing, acquires rotational kinetic energy. Angular momentum is conserved in the perfectly inelastic collision with the particle and the rotational

kinetic energy of the after-collision system is then transformed into gravitational potential energy as the rod-plus-particle swing upward. Let the zero of gravitational potential energy be at a distance L_1 below the pivot and use both angular momentum and mechanical energy conservation to relate the distances L_1 and L_2 and the mass M to m.

(*a*) Use conservation of energy to relate the initial and final potential energy of the rod to its rotational kinetic energy just before it collides with the particle:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_i = 0$,

$$K_f + U_f - U_i = 0$$

Substitute for K_f, U_f, and U_i to obtain:

$$\tfrac{1}{2}\left(\tfrac{1}{3}ML_1^2\right)\omega^2 + Mg\frac{L_1}{2} - MgL_1 = 0$$

Solving for ω yields:

$$\omega = \sqrt{\frac{3g}{L_1}}$$

Letting ω' represent the angular speed of the system after impact, use conservation of angular momentum to relate the angular momenta before and after the collision:

$$\Delta L = L_f - L_i = 0$$

or

$$\left(\tfrac{1}{3}ML_1^2 + mL_2^2\right)\omega' - \left(\tfrac{1}{3}ML_1^2\right)\omega = 0 \quad (1)$$

Solving for ω' and simplifying yields:

$$\omega' = \frac{\tfrac{1}{3}ML_1^2}{\tfrac{1}{3}ML_1^2 + mL_2^2}\omega = \frac{\tfrac{1}{3}ML_1^2}{\tfrac{1}{3}ML_1^2 + mL_2^2}\sqrt{\frac{3g}{L_1}}$$

Substitute numerical values and simplify to obtain:

$$\omega' = \frac{\tfrac{1}{3}(2.0\,\text{kg})(1.2\,\text{m})^2}{\tfrac{1}{3}(2.0\,\text{kg})(1.2\,\text{m})^2 + m(0.80\,\text{m})^2}\sqrt{\frac{3(9.81\,\text{m/s}^2)}{1.2\,\text{m}}} = \frac{4.75\,\text{kg/s}}{0.960\,\text{kg} + 0.64m}$$

Use conservation of energy to relate the rotational kinetic energy of the rod-plus-particle just after their collision to their potential energy when they have swung through an angle θ_{max}:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = 0$,

$$-K_i + U_f - U_i = 0$$

Substitute for K_i, U_f, and U_i to obtain:

$$-\tfrac{1}{2}I\omega'^2 + Mg\left(\tfrac{1}{2}L_1\right)\left(1-\cos\theta_{max}\right) + mgL_2\left(1-\cos\theta_{max}\right) = 0$$

Express the moment of inertia of the system with respect to the pivot:

$$I = \tfrac{1}{3}ML_1^2 + mL_2^2$$

Substitute for θ_{max}, I and ω' in equation (1) and simplify to obtain:

$$\frac{\tfrac{1}{2}(4.75\,\text{kg/s})^2}{0.960\,\text{kg} + 0.64m} = 0.2g\left(ML_1 + mL_2\right)$$

Substitute for M, L_1 and L_2 and simplify to obtain:

$$\frac{\tfrac{1}{2}(4.75\,\text{kg/s})^2}{0.960\,\text{kg} + 0.64m} = 0.2g\left(2.4\,\text{kg}\cdot\text{m} + (0.80\,\text{m})m\right)$$

Solve for m to obtain:

$$m = 1.18\,\text{kg} = \boxed{1.2\,\text{kg}}$$

(*b*) The energy dissipated in the inelastic collision is:

$$\Delta E = U_i - U_f \qquad (2)$$

Express U_i:

$$U_i = Mg\frac{L_1}{2}$$

Express U_f:

$$U_f = \left(1-\cos\theta_{max}\right)g\left(M\frac{L_1}{2} + mL_2\right)$$

Substitute for U_i and U_f in equation (2) to obtain:

$$\Delta E = Mg\frac{L_1}{2} - \left(1-\cos\theta_{max}\right)g\left(M\frac{L_1}{2} + mL_2\right)$$

Substitute numerical values and evaluate ΔE:

$$\Delta E = \frac{(2.0\,\text{kg})(9.81\,\text{m/s}^2)(1.2\,\text{m})}{2} - (1-\cos 37°)(9.81\,\text{m/s}^2)\left(\frac{(2.0\,\text{kg})(1.2\,\text{m})}{2} + (1.18\,\text{kg})(0.80\,\text{m})\right)$$

$$= \boxed{7.5\,\text{J}}$$

Precession

69 •• [SSM] A bicycle wheel that has a radius equal to 28 cm is mounted at the middle of an axle 50 cm long. The tire and rim weigh 30 N. The wheel is spun at 12 rev/s, and the axle is then placed in a horizontal position with one end resting on a pivot. (*a*) What is the angular momentum due to the spinning of the wheel? (Treat the wheel as a hoop.) (*b*) What is the angular velocity of precession? (*c*) How long does it take for the axle to swing through 360° around the pivot? (*d*) What is the angular momentum associated with the motion of the center of mass, that is, due to the precession? In what direction is this angular momentum?

Picture the Problem We can determine the angular momentum of the wheel and the angular velocity of its precession from their definitions. The period of the precessional motion can be found from its angular velocity and the angular momentum associated with the motion of the center of mass from its definition.

(*a*) Using the definition of angular momentum, express the angular momentum of the spinning wheel:

$$L = I\omega = MR^2\omega = \frac{w}{g}R^2\omega$$

Substitute numerical values and evaluate L:

$$L = \left(\frac{30\,\text{N}}{9.81\,\text{m/s}^2}\right)(0.28\,\text{m})^2 \times \left(12\frac{\text{rev}}{\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}}\right) = 18.1\,\text{J}\cdot\text{s} = \boxed{18\,\text{J}\cdot\text{s}}$$

(*b*) Using its definition, express the angular velocity of precession:

$$\omega_\text{p} = \frac{d\phi}{dt} = \frac{MgD}{L}$$

Substitute numerical values and evaluate ω_p:

$$\omega_p = \frac{(30\,\text{N})(0.25\,\text{m})}{18.1\,\text{J}\cdot\text{s}} = 0.414\,\text{rad/s}$$
$$= \boxed{0.41\,\text{rad/s}}$$

(*c*) Express the period of the precessional motion as a function of the angular velocity of precession:

$$T = \frac{2\pi}{\omega_p} = \frac{2\pi}{0.414\,\text{rad/s}} = \boxed{15\,\text{s}}$$

(*d*) Express the angular momentum of the center of mass due to the precession:

$$L_p = I_{cm}\omega_p = MD^2\omega_p$$

Substitute numerical values and evaluate L_p:

$$L_p = \left(\frac{30\,\text{N}}{9.81\,\text{m/s}^2}\right)(0.25\,\text{m})^2(0.414\,\text{rad/s})$$
$$= \boxed{0.079\,\text{J}\cdot\text{s}}$$

The direction of L_p is either up or down, depending on the direction of L.

70 •• A uniform disk, whose mass is 2.50 kg and radius is 6.40 cm is mounted at the center of a 10.0-cm-long axle and spun at 700 rev/min. The axle is then placed in a horizontal position with one end resting on a pivot. The other end is given an initial horizontal velocity such that the precession is smooth with no nutation. (*a*) What is the angular velocity of precession? (*b*) What is the speed of the center of mass during the precession? (*c*) What is the acceleration (magnitude and direction) of the center of mass? (*d*) What are the vertical and horizontal components of the force exerted by the pivot on the axle?

Picture the Problem The angular velocity of precession can be found from its definition. Both the speed and the magnitude of the acceleration of the center of mass during precession are related to the angular velocity of precession. We can use Newton's second law to find the vertical and horizontal components of the force exerted by the pivot on the axle.

(*a*) The angular velocity of precession is given by:

$$\omega_p = \frac{d\phi}{dt} = \frac{MgD}{I_s\omega_s}$$

Substituting for I_s and simplifying yields:

$$\omega_p = \frac{MgD}{\frac{1}{2}MR^2\omega_s} = \frac{2gD}{R^2\omega_s}$$

Substitute numerical values and evaluate ω_p:

$$\omega_p = \frac{2(9.81\,\text{m/s}^2)(0.050\,\text{m})}{(0.064\,\text{m})^2\left(700\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}\right)} = 3.27\,\text{rad/s} = \boxed{3.3\,\text{rad/s}}$$

(*b*) Express the speed of the center of mass in terms of its angular speed of precession:

$$v_{cm} = D\omega_p = (0.050\,\text{m})(3.27\,\text{rad/s}) = \boxed{16\,\text{cm/s}}$$

(*c*) Relate the acceleration of the center of mass to its angular speed of precession:

$$a_{cm} = D\omega_p^2 = (0.050\,\text{m})(3.27\,\text{rad/s})^2 = 0.535\,\text{m/s}^2 = \boxed{54\,\text{cm/s}^2}$$

(*d*) Use Newton's second law to relate the vertical component of the force exerted by the pivot to the weight of the disk:

$$F_v = Mg = (2.5\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{25\,\text{N}}$$

Relate the horizontal component of the force exerted by the pivot on the axle to the acceleration of the center of mass:

$$F_H = Ma_{cm} = (2.5\,\text{kg})(0.535\,\text{m/s}^2) = \boxed{1.3\,\text{N}}$$

General Problems

71 • [SSM] A particle whose mass is 3.0 kg moves in the *xy* plane with velocity $\vec{v} = (3.0\text{ m/s})\hat{i}$ along the line $y = 5.3$ m. (*a*) Find the angular momentum $\vec{L}$ about the origin when the particle is at (12 m, 5.3 m). (*b*) A force $\vec{F} = (-3.9\text{ N})\hat{i}$ is applied to the particle. Find the torque about the origin due to this force as the particle passes through the point (12 m, 5.3 m).

Picture the Problem While the 3-kg particle is moving in a straight line, it has angular momentum given by $\vec{L} = \vec{r}\times\vec{p}$ where $\vec{r}$ is its position vector and $\vec{p}$ is its linear momentum. The torque due to the applied force is given by $\vec{\tau} = \vec{r}\times\vec{F}$.

(*a*) The angular momentum of the particle is given by:

$$\vec{L} = \vec{r}\times\vec{p}$$

Express the vectors $\vec{r}$ and $\vec{p}$:

$$\vec{r} = (12\,\text{m})\hat{i} + (5.3\,\text{m})\hat{j}$$

and

$$\vec{p} = mv\hat{\mathbf{i}} = (3.0\,\text{kg})(3.0\,\text{m/s})\hat{i} = (9.0\,\text{kg}\cdot\text{m/s})\hat{i}$$

Substitute for $\vec{r}$ and $\vec{p}$:and simplify to find $\vec{L}$:

$$\vec{L} = \left[(12\,\text{m})\hat{i} + (5.3\,\text{m})\hat{j}\right]\times(9.0\,\text{kg}\cdot\text{m/s})\hat{i} = (47.7\,\text{kg}\cdot\text{m}^2/\text{s})(\hat{j}\times\hat{i}) = \boxed{-(48\,\text{kg}\cdot\text{m}^2/\text{s})\hat{k}}$$

(*b*) Using its definition, express the torque due to the force:

$$\vec{\tau} = \vec{r}\times\vec{F}$$

Substitute for $\vec{r}$ and $\vec{F}$ and simplify to find $\vec{\tau}$:

$$\vec{\tau} = \left[(12\,\text{m})\hat{i} + (5.3\,\text{m})\hat{j}\right]\times(-3.9\,\text{N})\hat{i} = -(15.9\,\text{N}\cdot\text{m})(\hat{j}\times\hat{i}) = \boxed{(21\,\text{N}\cdot\text{m})\hat{k}}$$

72 • The position vector of a particle whose mass is 3.0 kg is given by $\vec{r} = 4.0\,\hat{i} + 3.0t^2\,\hat{j}$, where $\vec{r}$ is in meters and *t* is in seconds. Determine the angular momentum and net torque, about the origin, acting on the particle.

Picture the Problem The angular momentum of the particle is given by $\vec{L} = \vec{r}\times\vec{p}$ where $\vec{r}$ is its position vector and $\vec{p}$ is its linear momentum. The torque acting on the particle is given by $\vec{\tau} = d\vec{L}/dt$.

The angular momentum of the particle is given by:

$$\vec{L} = \vec{r}\times\vec{p} = \vec{r}\times m\vec{v} = m\vec{r}\times\vec{v} = m\vec{r}\times\frac{d\vec{r}}{dt}$$

Evaluating $\frac{d\vec{r}}{dt}$ yields:

$$\frac{d\vec{r}}{dt} = \frac{d}{dt}\left[4.0\hat{i} + 3.0t^2\hat{j}\right] = (6.0t)\hat{j}$$

Substitute for $m\vec{r}$ and $\frac{d\vec{r}}{dt}$ and simplify to find $\vec{L}$:

$$\vec{L} = \left[(3.0\,\text{kg})\left\{(4.0\,\text{m})\hat{i} + (3.0t^2\,\text{m/s}^2)\hat{j}\right\}\right]\times(6.0t\,\text{m/s})\hat{j} = \boxed{(72t\,\text{J}\cdot\text{s})\hat{k}}$$

Find the net torque due to the force:

$$\vec{\tau}_{\text{net}} = \frac{d\vec{L}}{dt} = \frac{d}{dt}\left[(72t\,\text{J}\cdot\text{s})\hat{k}\right] = \boxed{(72\,\text{N}\cdot\text{m})\hat{k}}$$

73 •• Two ice skaters, whose masses are 55 kg and 85 kg, hold hands and rotate about a vertical axis that passes between them, making one revolution in 2.5 s. Their centers of mass are separated by 1.7 m and their center of mass is stationary. Model each skater as a point particle and find (*a*) the angular momentum of the system about their center of mass and (*b*) the total kinetic energy of the system.

Picture the Problem The ice skaters rotate about their center of mass; a point we can locate using its definition. Knowing the location of the center of mass we can determine their moment of inertia with respect to an axis through this point. The angular momentum of the system is then given by $L = I_{\text{cm}}\omega$ and its kinetic energy can be found from $K = L^2/(2I_{\text{cm}})$.

(*a*) Express the angular momentum of the system about the center of mass of the skaters:

$$L = I_{\text{cm}}\omega$$

Using its definition, locate the center of mass, relative to the 85-kg skater, of the system:

$$x_{\text{cm}} = \frac{(55\,\text{kg})(1.7\,\text{m}) + (85\,\text{kg})(0)}{55\,\text{kg} + 85\,\text{kg}} = 0.668\,\text{m}$$

Calculate I_{cm}:

$$I_{\text{cm}} = (55\,\text{kg})(1.7\,\text{m} - 0.668\,\text{m})^2 + (85\,\text{kg})(0.668\,\text{m})^2 = 96.5\,\text{kg}\cdot\text{m}^2$$

Substitute to determine L:

$$L = \left(96.5\,\text{kg}\cdot\text{m}^2\right)\left(\frac{1\,\text{rev}}{2.5\,\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}}\right) = 243\,\text{J}\cdot\text{s} = \boxed{0.24\,\text{kJ}\cdot\text{s}}$$

(*b*) Relate the total kinetic energy of the system to its angular momentum and evaluate K:

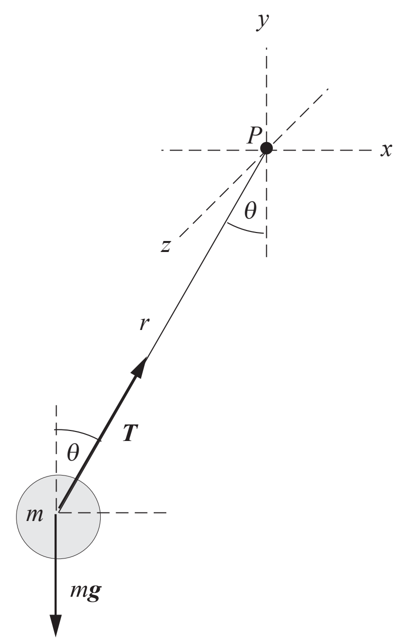
$$K = \frac{L^2}{2I_{\text{cm}}}$$

Substitute numerical values and evaluate K:

$$K = \frac{(243\,\text{J}\cdot\text{s})^2}{2\left(96.5\,\text{kg}\cdot\text{m}^2\right)} = \boxed{0.31\,\text{kJ}}$$

74 •• A 2.0-kg ball attached to a string whose length is 1.5 m moves counterclockwise (as viewed from above) in a horizontal circle (Figure 10-56). The string makes an angle $\theta = 30°$ with the vertical. (*a*) Determine both the horizontal and vertical components of the angular momentum $\vec{L}$ of the ball about the point of support *P*. (*b*) Find the magnitude of $d\vec{L}/dt$ and verify that it equals the magnitude of the torque exerted by gravity about the point of support.

Picture the Problem Let the origin of the coordinate system be at the pivot. The diagram shows the forces acting on the ball. We'll apply Newton's second law to the ball to determine its speed. We'll then use the derivative of its position vector to express its velocity and the definition of angular momentum to show that $\vec{L}$ has both horizontal and vertical components. We can use the derivative of $\vec{L}$ with respect to time to show that the rate at which the angular momentum of the ball changes is equal to the torque, relative to the pivot point, acting on it.



(*a*) Express the angular momentum of the ball about the point of support:

$$\vec{L} = \vec{r} \times \vec{p} = m\vec{r} \times \vec{v} \qquad (1)$$

Apply Newton's second law to the ball:

$$\sum F_x = T\sin\theta = m\frac{v^2}{r\sin\theta}$$

and

$$\sum F_z = T\cos\theta - mg = 0$$

Eliminate *T* between these equations and solve for *v* to obtain:

$$v = \sqrt{rg\sin\theta\tan\theta}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{(1.5\,\text{m})(9.81\,\text{m/s}^2)\sin 30°\tan 30°} = 2.06\,\text{m/s}$$

Express the position vector of the ball:

$$\vec{r} = (1.5\,\text{m})\sin 30°\left(\cos\omega t\,\hat{\boldsymbol{i}} + \sin\omega t\hat{\boldsymbol{j}}\right) - (1.5\,\text{m})\cos 30°\hat{\boldsymbol{k}}$$

The velocity of the ball is:

$$\vec{v} = \frac{d\vec{r}}{dt} = (0.75\omega\,\text{m/s})\left(-\sin\omega t\,\hat{i} + \cos\omega t\,\hat{j}\right)$$

Evaluating ω yields:

$$\omega = \frac{2.06\,\text{m/s}}{(1.5\,\text{m})\sin 30°} = 2.75\,\text{rad/s}$$

Substitute for ω to obtain:

$$\vec{v} = (2.06\,\text{m/s})\left(-\sin\omega t\,\hat{i} + \cos\omega t\hat{j}\right)$$

Substitute in equation (1) and evaluate $\vec{L}$:

$$\begin{aligned}\vec{L} &= (2.0\,\text{kg})\left[(1.5\,\text{m})\sin 30°\left(\cos\omega t\,\hat{i} + \sin\omega t\,\hat{j}\right) - (1.5\,\text{m})\cos 30°\hat{k}\right] \\ &\qquad \times\left[(2.06\,\text{m/s})\left(-\sin\omega t\,\hat{i} + \cos\omega t\,\hat{j}\right)\right] \\ &= (5.35\,\text{J}\cdot\text{s})\cos\omega t\,\hat{i} + (5.35\,\text{J}\cdot\text{s})\sin\omega t\,\hat{j} + (3.09\,\text{J}\cdot\text{s})\hat{k}\end{aligned}$$

The horizontal component of $\vec{L}$ is the component in the xy plane:

$$\vec{L}_{\text{hor}} = \boxed{(5.4\,\text{J}\cdot\text{s})\cos\omega t\,\hat{i} + (5.4\,\text{J}\cdot\text{s})\sin\omega t\,\hat{j}}$$

The vertical component of $\vec{L}$ is its z component:

$$\vec{L}_{\text{vertical}} = \boxed{(3.1\,\text{J}\cdot\text{s})\hat{k}}$$

(*b*) Evaluate $\dfrac{d\vec{L}}{dt}$:

$$\frac{d\vec{L}}{dt} = \left[5.36\omega\left(-\sin\omega t\,\hat{i} + \cos\omega t\hat{j}\right)\right]\text{J}$$

Evaluate the magnitude of $\dfrac{d\vec{L}}{dt}$:

$$\left|\frac{d\vec{L}}{dt}\right| = (5.36\,\text{N}\cdot\text{m}\cdot\text{s})(2.75\,\text{rad/s}) = \boxed{15\,\text{N}\cdot\text{m}}$$

Express the magnitude of the torque exerted by gravity about the point of support:

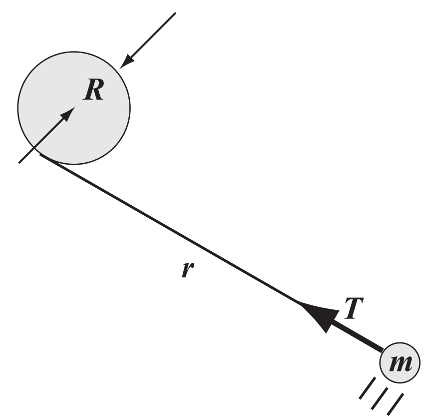
$$\tau = mgr\sin\theta$$

Substitute numerical values and evaluate τ:

$$\tau = (2.0\,\text{kg})(9.81\,\text{m/s}^2)(1.5\,\text{m})\sin 30° = \boxed{15\,\text{N}\cdot\text{m}}$$

75 •• A compact object whose mass is m resting on a horizontal, frictionless surface is attached to a string that wraps around a vertical cylindrical post attached to the surface. Thus, when the object is set into motion, it follows a path that spirals inward. (*a*) Is the angular momentum of the object about the axis of the post conserved? Explain your answer. (*b*) Is the energy of the object conserved? Explain your answer. (*c*) If the speed of the object is v_0 when the unwrapped length of the string is r, what is its speed when the unwrapped length has shortened to $r/2$?

Picture the Problem The pictorial representation depicts the object rotating counterclockwise around the cylindrical post. Let the system be the object. In Part (*a*) we need to decide whether a net torque acts on the object and in Part (*b*) the issue is whether any external forces act on the object. In Part (*c*) we can apply the definition of kinetic energy to find the speed of the object when the unwrapped length has shortened to $r/2$.



(*a*) The net torque acting on the object is given by:

$$\tau_{\text{net}} = \frac{dL}{dt} = RT$$

Because $\tau_{\text{net}} \neq 0$, angular momentum is not conserved.

(*b*) Because, in this frictionless environment, the net external force acting on the object is the tension force and it acts at right angles to the object's velocity, the energy of the object is conserved.

(*c*) Apply conservation of mechanical energy to the object to obtain:

$$\Delta E = \Delta K + \Delta U = 0$$

or, because $\Delta U = 0$,

$$\Delta K_{\text{rot}} = 0$$

Substituting for the kinetic energies yields:

$$\tfrac{1}{2}I'\omega'^2 - \tfrac{1}{2}I\omega_0^2 = 0$$

or

$$I'\omega'^2 - I\omega_0^2 = 0$$

Substitute for I, I', ω', and ω_0 to obtain:

$$\tfrac{1}{2}m\left(\frac{r}{2}\right)^2\left(\frac{v'}{\frac{r}{2}}\right)^2 - \tfrac{1}{2}mr^2\left(\frac{v_0}{r}\right)^2 = 0$$

Solving for v' yields:

$$v' = \boxed{v_0}$$

76 •• Figure 10-57 shows a hollow cylindrical tube that has a mass M, a length L, and a moment of inertia $ML^2/10$. Inside the cylinder are two disks each of mass m, separated by a distance ℓ, and tied to a central post by a thin string. The system can rotate about a vertical axis through the center of the cylinder. You are designing this cylinder-disk apparatus to shut down the rotations when the strings break by triggering an electronic "shutoff" signal (sent to the rotating motor) when the disks hit the ends of the cylinder. During development, you notice that with the system rotating at some critical angular speed ω, the string suddenly breaks. When the disks reach the ends of the cylinder, they stick. Obtain expressions for the final angular speed and the initial and final kinetic energies of the system. Assume that the inside walls of the cylinder are frictionless.

Picture the Problem Because the net torque acting on the system is zero; we can use conservation of angular momentum to relate the initial and final angular velocities of the system. See Table 9-1 for the moment of inertia of a disk.

Using conservation of angular momentum, relate the initial and final angular speeds to the initial and final moments of inertia:

$$\Delta L = L_f - L_i = 0$$

or

$$I_f\omega_f - I_i\omega_i = 0$$

Solving for ω_f yields:

$$\omega_f = \frac{I_i}{I_f}\omega_i = \frac{I_i}{I_f}\omega \qquad (1)$$

Use the parallel-axis theorem to express the moment of inertia of each of the disks with respect to the axis of rotation:

$$\begin{aligned} I_{\text{i, each disk}} &= I_{\text{cm}} + m\left(\tfrac{1}{2}\ell\right)^2 \\ &= \tfrac{1}{4}mr^2 + \tfrac{1}{4}m\ell^2 \\ &= \tfrac{1}{4}m\left(r^2 + \ell^2\right) \end{aligned}$$

Express the initial moment of inertia I_i of the cylindrical tube plus disks system:

$$\begin{aligned} I_i &= I_{\substack{\text{cylindrical}\\ \text{tube}}} + 2I_{\text{i, each disk}} \\ &= \tfrac{1}{10}ML^2 + 2\left[\tfrac{1}{4}m\left(r^2+\ell^2\right)\right] \\ &= \tfrac{1}{10}ML^2 + \tfrac{1}{2}m\left(r^2+\ell^2\right) \end{aligned}$$

When the disks have moved out to the end of the cylindrical tube:

$$I_f = \tfrac{1}{10}ML^2 + \tfrac{1}{2}m\left(r^2 + L^2\right)$$

Substitute for I_i and I_f in equation (1) and simplify to obtain:

$$\omega_f = \frac{\tfrac{1}{10}ML^2 + \tfrac{1}{2}m\left(r^2 + \ell^2\right)}{\tfrac{1}{10}ML^2 + \tfrac{1}{2}m\left(r^2 + L^2\right)}\omega = \boxed{\frac{ML^2 + 5m\left(r^2 + \ell^2\right)}{ML^2 + 5m\left(r^2 + L^2\right)}\omega}$$

The initial kinetic energy of the system is:

$$K_i = \tfrac{1}{2}I_i\omega^2$$

Substituting for I_i and simplifying yields:

$$K_i = \tfrac{1}{2}\left[\tfrac{1}{10}ML^2 + \tfrac{1}{2}m\left(r^2 + \ell^2\right)\right]\omega^2 = \boxed{\left[\tfrac{1}{20}ML^2 + \tfrac{1}{4}m\left(r^2 + \ell^2\right)\right]\omega^2}$$

The final kinetic energy of the system is:

$$K_f = \tfrac{1}{2}I_f\omega_f^2$$

Substitute for I_f and ω_f and simplify to obtain:

$$K_f = \tfrac{1}{2}\left[\tfrac{1}{10}ML^2 + \tfrac{1}{2}m\left(r^2 + L^2\right)\right]\left(\frac{ML^2 + 5m\left(r^2 + \ell^2\right)}{ML^2 + 5m\left(r^2 + L^2\right)}\omega\right)^2 = \boxed{\tfrac{1}{20}\left[\frac{\left[ML^2 + 5m\left(r^2 + \ell^2\right)\right]^2}{ML^2 + 5m\left(r^2 + L^2\right)}\right]\omega^2}$$

77 •• [SSM] Repeat Problem 76, this time friction between the disks and the walls of the cylinder is not negligible. However, the coefficient of friction is not great enough to prevent the disks from reaching the ends of the cylinder. Can the final kinetic energy of the system be determined without knowing the coefficient of kinetic friction?

Determine the Concept Yes. The solution depends only upon conservation of angular momentum of the system, so it depends only upon the initial and final moments of inertia.

78 •• Suppose that in Figure 10-57 $\ell = 0.60$ m, $L = 2.0$ m, $M = 0.80$ kg, and $m = 0.40$ kg. The string breaks when the system's angular speed approaches the critical angular speed ω_i, at which time the tension in the string is 108 N. The masses then move radially outward until they undergo perfectly inelastic collisions with the ends of the cylinder. Determine the critical angular speed and the angular speed of the system after the inelastic collisions. Find the total kinetic

energy of the system at the critical angular speed, and again after the inelastic collisions. Assume that the inside walls of the cylinder are frictionless.

Picture the Problem Because the net torque acting on the system is zero; we can use conservation of angular momentum to relate the initial and final angular speeds of the system.

Using conservation of angular momentum, relate the initial and final angular speeds to the initial and final moments of inertia:

$$\Delta L = L_f - L_i = 0$$

or

$$I_f\omega_f - I_i\omega_i = 0 \Rightarrow \omega_f = \frac{I_i}{I_f}\omega_i \quad (1)$$

Express the tension in the string as a function of the critical angular speed of the system:

$$T = mr\omega_i^2 = m\frac{\ell}{2}\omega_i^2 \Rightarrow \omega_i = \sqrt{\frac{2T}{m\ell}}$$

Substitute numerical values and evaluate ω_i:

$$\omega_i = \sqrt{\frac{2(108\,\text{N})}{(0.40\,\text{kg})(0.60\,\text{m})}} = 30.0\,\text{rad/s}$$
$$= \boxed{30\,\text{rad/s}}$$

Express I_i:

$$I_i = \tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}m\ell^2\right)$$

Substitute numerical values and evaluate I_i:

$$I_i = \tfrac{1}{10}(0.80\,\text{kg})(2.0\,\text{m})^2 + \tfrac{1}{2}(0.40\,\text{kg})(0.60\,\text{m})^2$$
$$= 0.392\,\text{kg}\cdot\text{m}^2$$

Express I_f:

$$I_f = \tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}mL^2\right)$$

Substitute numerical values and evaluate I_f:

$$I_f = \tfrac{1}{10}(0.80\,\text{kg})(2.0\,\text{m})^2 + \tfrac{1}{2}(0.40\,\text{kg})(2.0\,\text{m})^2$$
$$= 1.12\,\text{kg}\cdot\text{m}^2$$

Substitute numerical values in equation (1) and evaluate ω_f:

$$\omega_f = \frac{0.392\,\text{kg}\cdot\text{m}^2}{1.12\,\text{kg}\cdot\text{m}^2}(30.0\,\text{rad/s})$$
$$= 10.5\,\text{rad/s} = \boxed{11\,\text{rad/s}}$$

The total kinetic energy of the system at the critical angular speed is:

$$K_i = \tfrac{1}{2} I_i \omega_i^2$$

Substitute numerical values and evaluate K_i:

$$K_i = \tfrac{1}{2}\left(0.392\,\text{kg}\cdot\text{m}^2\right)\left(30.0\,\text{rad/s}\right)^2 = 176\,\text{J} = \boxed{0.18\,\text{kJ}}$$

The total kinetic energy of the system after the inelastic collisions is:

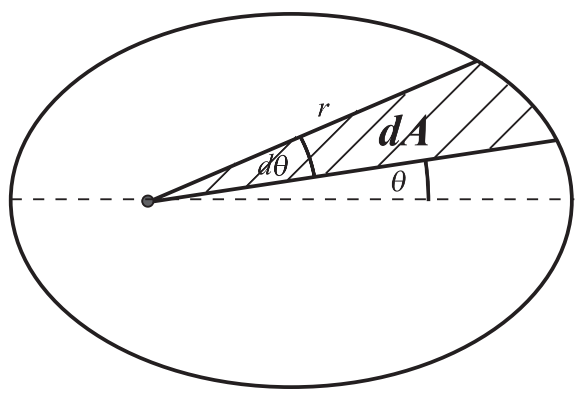
$$K_f = \tfrac{1}{2} I_f \omega_f^2$$

Substitute numerical values and evaluate K_f:

$$K_f = \tfrac{1}{2}\left(1.12\,\text{kg}\cdot\text{m}^2\right)\left(10.5\,\text{rad/s}\right)^2 = \boxed{62\,\text{J}}$$

79 •• [SSM] Kepler's second law states: *The line from the center of the Sun to the center of a planet sweeps out equal areas in equal times.* Show that this law follows directly from the law of conservation of angular momentum and the fact that the force of gravitational attraction between a planet and the Sun acts along the line joining the centers of the two celestial objects.

Picture the Problem The pictorial representation shows an elliptical orbit. The triangular element of the area is $dA = \frac{1}{2}r(rd\theta) = \frac{1}{2}r^2 d\theta$.



Differentiate dA with respect to t to obtain:

$$\frac{dA}{dt} = \tfrac{1}{2}r^2\frac{d\theta}{dt} = \tfrac{1}{2}r^2\omega \qquad (1)$$

Because the gravitational force acts along the line joining the two objects, $\tau = 0$. Hence:

$$L = mr^2\omega = \text{constant} \qquad (2)$$

Eliminate $r^2\omega$ between equations (1) and (2) to obtain:

$$\frac{dA}{dt}=\boxed{\frac{L}{2m}=\text{constant}}$$

80 •• Consider a cylindrical turntable whose mass is *M* and radius is *R*, turning with an initial angular speed ω_1. (*a*) A parakeet of mass *m*, hovering in flight above the outer edge of the turntable, gently lands on it and stays in one place on it as shown in Figure 10-58. What is the angular speed of the turntable after the parakeet lands? (*b*) Becoming dizzy, the parakeet jumps off (not flies off) with a velocity $\vec{v}$ relative to the turntable. The direction of $\vec{v}$ is tangent to the edge of the turntable, and in the direction of its rotation. What will be the angular speed of the turntable afterwards? Express your answer in terms of the two masses *m* and *M*, the radius *R*, the parakeet speed *v* and the initial angular speed ω_1.

Picture the Problem The angular momentum of the turntable-parakeet is conserved in both parts of this problem.

(*a*) Apply conservation of angular momentum to the turntable-parakeet system as the parakeet lands to obtain:

$$\Delta L=L_f-L_i=0 \qquad (1)$$

The final angular momentum of the system is given by:

$$\begin{aligned}L_f&=L_{\text{turntable}}+L_{\text{parakeet}}\\&=I_{\text{turntable}}\omega_f+\left|\vec{r}\times\vec{p}_{\text{parakeet}}\right|\end{aligned}$$

Because $I_{\text{turntable}}=\frac{1}{2}MR^2$ and $\left|\vec{r}\times\vec{p}_{\text{parakeet}}\right|=Rmv_{\text{parakeet}}$:

$$\begin{aligned}L_f&=\tfrac{1}{2}MR^2\omega_f+Rmv_{\text{parakeet}}\\&=\tfrac{1}{2}MR^2\omega_f+Rm(R\omega_f)\\&=\tfrac{1}{2}MR^2\omega_f+mR^2\omega_f\end{aligned}$$

The initial angular momentum of the system is given by:

$$L_i=I_{\text{turntable}}\omega_i=\tfrac{1}{2}MR^2\omega_i$$

Substituting for L_f and L_i in equation (1) yields:

$$\tfrac{1}{2}MR^2\omega_f+mR^2\omega_f-\tfrac{1}{2}MR^2\omega_i=0$$

Solve for ω_f to obtain:

$$\omega_f=\boxed{\frac{M}{M+2m}\omega_i}$$

(*b*) Apply conservation of angular momentum to the turntable-parakeet system as the parakeet jumps off to obtain:

$$\Delta L = L_f - L_i = 0 \qquad (2)$$

The final angular momentum of the system is given by:

$$L_f = L_{\text{turntable}} + L_{\text{parakeet}} = I_{\text{turntable}}\omega_f + \left|\vec{\boldsymbol{r}} \times \vec{\boldsymbol{p}}_{\text{parakeet}}\right|$$

Because $I_{\text{turntable}} = \frac{1}{2}MR^2$ and $\left|\vec{\boldsymbol{r}} \times \vec{\boldsymbol{p}}_{\text{parakeet}}\right| = Rmv_{\text{parakeet}}$:

$$L_f = \tfrac{1}{2}MR^2\omega_f + Rmv_{\text{parakeet}} \qquad (3)$$

Express the speed of the parakeet relative to the ground:

$$v_{\text{parakeet}} = v_{\text{turntable}} + v = R\omega_f + v$$

Using the expression derived in (*a*), substitute for ω_f to obtain:

$$v_{\text{parakeet}} = \frac{M}{M+2m}R\omega_i + v$$

Substituting for v_{parakeet} in equation (3) and simplifying yields:

$$L_f = \tfrac{1}{2}MR^2\omega_f + mR\left(\frac{M}{M+2m}R\omega_i + v\right)$$

The initial angular momentum of the system is the same as the final angular momentum in (*a*):

$$L_i = \tfrac{1}{2}MR^2\omega_i$$

Substituting for L_f and L_i in equation (2) yields:

$$\tfrac{1}{2}MR^2\omega_f + mR\left[\left(\frac{M}{M+2m}\right)R\omega_i + v\right] - \tfrac{1}{2}MR^2\omega_i = 0$$

Solving for ω_f gives:

$$\omega_f = \boxed{\frac{M}{M+2m}\omega_i - 2\left(\frac{m}{M}\right)\frac{v}{R}}$$

81 •• You are given a heavy but thin metal disk (like a coin, but larger; Figure 10-59). (Objects like this are called *Euler disks.*) Placing the disk on a turntable, you spin the disk, on edge, about a vertical axis through a diameter of the disk and the center of the turntable. As you do this, you hold the turntable still with your other hand, letting it go immediately after you spin the disk. The turntable is a uniform solid cylinder with a radius equal to 0.250 m and a mass equal to 0.735 kg and rotates on a frictionless bearing. The disk has an initial angular speed of 30.0 rev/min. (*a*) The disk spins down and falls over, finally

coming to rest on the turntable with its symmetry axis coinciding with the turntable's. What is the final angular speed of the turntable? (*b*) What will be the final angular speed if the disk's symmetry axis ends up 0.100 m from the axis of the turntable?

Picture the Problem Let the letters *d*, *m*, and *r* denote the disk and the letters *t*, *M*, and *R* the turntable. We can use conservation of angular momentum to relate the final angular speed of the turntable to the initial angular speed of the Euler disk and the moments of inertia of the turntable and the disk. In part (*b*) we'll need to use the parallel-axis theorem to express the moment of inertia of the disk with respect to the rotational axis of the turntable. You can find the moments of inertia of the disk in its two orientations and that of the turntable in Table 9-1.

(*a*) Use conservation of angular momentum to relate the initial and final angular momenta of the system:

$$I_{\text{df}}\omega_{\text{df}} + I_{\text{tf}}\omega_{\text{tf}} - I_{\text{di}}\omega_{\text{di}} = 0$$

Because $\omega_{\text{tf}} = \omega_{\text{df}}$:

$$I_{\text{df}}\omega_{\text{tf}} + I_{\text{tf}}\omega_{\text{tf}} - I_{\text{di}}\omega_{\text{di}} = 0$$

Solving for ω_{tf} yields:

$$\omega_{\text{tf}} = \frac{I_{\text{di}}}{I_{\text{df}} + I_{\text{tf}}}\omega_{\text{di}} \qquad (1)$$

Ignoring the negligible thickness of the disk, express its initial moment of inertia:

$$I_{\text{di}} = \tfrac{1}{4}mr^2$$

Express the final moment of inertia of the disk:

$$I_{\text{df}} = \tfrac{1}{2}mr^2$$

Express the final moment of inertia of the turntable:

$$I_{\text{tf}} = \tfrac{1}{2}MR^2$$

Substitute in equation (1) and simplify to obtain:

$$\omega_{\text{tf}} = \frac{\tfrac{1}{4}mr^2}{\tfrac{1}{2}mr^2 + \tfrac{1}{2}MR^2}\omega_{\text{di}} = \frac{1}{2 + 2\dfrac{MR^2}{mr^2}}\omega_{\text{di}} \qquad (2)$$

Express ω_{di} in rad/s:

$$\omega_{\text{di}} = 30.0\frac{\text{rev}}{\text{min}} \times \frac{2\pi\,\text{rad}}{\text{rev}} \times \frac{1\,\text{min}}{60\,\text{s}} = \pi\ \text{rad/s}$$

Substitute numerical values in equation (2) and evaluate ω_{tf}:

$$\omega_{\text{tf}} = \frac{\pi\ \text{rad/s}}{2 + 2\dfrac{(0.735\,\text{kg})(0.250\,\text{m})^2}{(0.500\,\text{kg})(0.125\,\text{m})^2}} = \boxed{0.228\,\text{rad/s}}$$

(*b*) Use the parallel-axis theorem to express the final moment of inertia of the disk when it is a distance L from the center of the turntable:

$$I_{\text{df}} = \tfrac{1}{2}mr^2 + mL^2 = m\left(\tfrac{1}{2}r^2 + L^2\right)$$

Substitute in equation (1) to obtain:

$$\omega_{\text{tf}} = \frac{\frac{1}{4}mr^2}{m\left(\frac{1}{2}r^2 + L^2\right) + \frac{1}{2}MR^2}\omega_{\text{di}} = \frac{1}{2 + 4\dfrac{L^2}{r^2} + 2\dfrac{MR^2}{mr^2}}\omega_{\text{di}}$$

Substitute numerical values and evaluate ω_{tf}:

$$\omega_{\text{tf}} = \frac{\pi\ \text{rad/s}}{2 + 4\dfrac{(0.100\,\text{m})^2}{(0.125\,\text{m})^2} + 2\dfrac{(0.735\,\text{kg})(0.250\,\text{m})^2}{(0.500\,\text{kg})(0.125\,\text{m})^2}} = \boxed{0.192\,\text{rad/s}}$$

82 •• (*a*) Assuming Earth to be a homogeneous sphere that has a radius r and a mass m, show that the period T (time for one daily rotation) of Earth's rotation about its axis is related to its radius by $T = br^2$, where $b = (4/5)\pi m/L$. Here L is the magnitude of the spin angular momentum of Earth. (*b*) Suppose that the radius r changes by a very small amount Δr due to some internal cause such as thermal expansion. Show that the fractional change in the period ΔT is given approximately by $\Delta T/T = 2\Delta r/r$. (*c*) By how many kilometers would r need to increase for the period to change by 0.25 d/y (so that leap years would no longer be necessary)?

Picture the Problem We can express the period of Earth's rotation in terms of its angular velocity of rotation and relate its angular velocity to its angular momentum and moment of inertia with respect to an axis through its center. We can differentiate this expression with respect to T and then use differentials to approximate the changes in r and T.

(*a*) Express the period of Earth's rotation in terms of its angular velocity of rotation:

$$T = \frac{2\pi}{\omega}$$

Relate Earth's angular speed to its angular momentum and moment of inertia:

$$\omega = \frac{L}{I} = \frac{L}{\frac{2}{5}mr^2}$$

Substitute for ω and simplify to obtain:

$$T = \frac{2\pi\left(\frac{2}{5}mr^2\right)}{L} = \boxed{\frac{4\pi m}{5L}r^2}$$

(*b*) Find dT/dr:

$$\frac{dT}{dr} = \frac{d}{dr}\left(\frac{4\pi m}{5L}r^2\right) = 2\left(\frac{4\pi m}{5L}\right)r$$
$$= 2\left(\frac{T}{r^2}\right)r = \frac{2T}{r}$$

Solving for dT/T yields:

$$\frac{dT}{T} = 2\frac{dr}{r} \Rightarrow \frac{\Delta T}{T} \approx \boxed{2\frac{\Delta r}{r}}$$

(*c*) Using the equation we just derived, substitute for the change in the period of Earth:

$$\frac{\Delta T}{T} = \frac{\frac{1}{4}\,\text{d}}{\text{y}} \times \frac{1\,\text{y}}{365.24\,\text{d}} = \frac{1}{1460} = 2\frac{\Delta r}{r}$$

Solving for Δr yields:

$$\Delta r = \frac{r}{2(1460)}$$

Substitute numerical values and evaluate Δr:

$$\Delta r = \frac{6.37\times10^3\ \text{km}}{2(1460)} = \boxed{2.18\,\text{km}}$$

83 •• [SSM] The term *precession of the equinoxes* refers to the fact that Earth's spin axis does not stay fixed but sweeps out a cone once every 26,000 y. (This explains why our pole star, Polaris, will not remain the pole star forever.) The reason for this instability is that Earth is a giant gyroscope. The spin axis of Earth precesses because of the torques exerted on it by the gravitational forces of the Sun and moon. The angle between the direction of Earth's spin axis and the normal to the ecliptic plane (the plane of Earth's orbit) is 22.5 degrees. Calculate an approximate value for this torque, given that the period of rotation of Earth is 1.00 d and its moment of inertia is 8.03×10^{37} kg·m^2.

Picture the Problem Let ω_P be the angular velocity of precession of Earth-as-gyroscope, ω_s its angular velocity about its spin axis, and I its moment of inertia with respect to an axis through its poles, and relate ω_P to ω_s and I using its definition.

Use its definition to express the precession rate of Earth as a giant gyroscope:

$$\omega_P = \frac{\tau}{L}$$

Substitute for I and solve for τ to obtain:

$$\tau = L\omega_P = I\omega\omega_P$$

The angular velocity ω_s of Earth about its spin axis is given by:

$\omega = \dfrac{2\pi}{T}$ where T is the period of rotation of Earth.

Substitute for ω to obtain:

$$\tau = \frac{2\pi\, I\omega_P}{T}$$

Substitute numerical values and evaluate τ:

$$\tau = \frac{2\pi\left(8.03\times10^{37}\ \text{kg}\cdot\text{m}^2\right)\left(7.66\times10^{-12}\ \text{s}^{-1}\right)}{1\,\text{d}\times\dfrac{24\,\text{h}}{\text{d}}\times\dfrac{3600\,\text{s}}{\text{h}}} = \boxed{4.47\times10^{22}\ \text{N}\cdot\text{m}}$$

84 •• As indicated in the text, according to the Standard Model of Particle Physics, electrons are point-like particles having no spatial extent. (This assumption has been confirmed experimentally, and the radius of the electron has been shown to be less than 10^{-18} m.) The intrinsic spin of an electron could *in principle* be due to its rotation. Let's check to see if this conclusion is feasible. (*a*) Assuming that the electron is a uniform sphere whose radius is 1.00×10^{-18} m, what angular speed would be necessary to produce the observed intrinsic angular momentum of $\hbar/2$? (*b*) Using this value of angular speed, show that the speed of a point on the ″equator″ of a ″spinning″ electron would be moving faster than the speed of light. What is your conclusion about the spin angular momentum being analogous to a spinning sphere with spatial extent?

Picture the Problem We can use the definition of the angular momentum of a spinning sphere, together with the expression for its moment of inertia, to find the angular speed of a point on the surface of a spinning electron. The speed of such a point is directly proportional to the angular speed of the sphere.

(*a*) Express the angular momentum of the spinning electron:

$$L = I\omega = \tfrac{1}{2}\hbar$$

Assuming a spherical electron of radius R, its moment of inertia, relative to its spin axis, is:

$$I = \tfrac{2}{5}MR^2$$

Substituting for I yields:

$$\tfrac{2}{5}MR^2\omega = \tfrac{1}{2}\hbar \Rightarrow \omega = \frac{5\hbar}{4MR^2}$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{5\left(1.05\times10^{-34}\ \text{J}\cdot\text{s}\right)}{4\left(9.11\times10^{-31}\ \text{kg}\right)\left(10^{-18}\ \text{m}\right)^2} = \boxed{1.44\times10^{32}\ \text{rad/s}}$$

(b) The speed of a point on the "equator" of a spinning electron of radius R is given by:

$$v = R\omega$$

Substitute numerical values and evaluate v:

$$v = \left(10^{-18}\ \text{m}\right)\left(1.44\times10^{32}\ \text{rad/s}\right) = \boxed{1.44\times10^{14}\ \text{m/s}} > c$$

Given that our model predicts a value for the speed of a point on the "equator" of a spinning electron that is greater than the speed of light, the idea that the spin angular momentum of an electron is analogous to that of a spinning sphere with spatial extent lacks credibility.

85 •• An interesting phenomenon occurring in certain *pulsars* (see Problem 24) is an event known as a "spin glitch," that is, a quick change in the spin rate of the pulsar due to a shift in mass location and a resulting rotational inertia change. Imagine a pulsar whose radius is 10.0 km and whose period of rotation is 25.032 ms. The rotation period is observed to suddenly decrease from 25.032 ms to 25.028 ms. If that decrease was related to a contraction of the star, by what amount would the pulsar radius have had to change?

Picture the Problem We can apply the conservation of angular momentum to the shrinking pulsar to relate its radii to the observed periods.

The change in the radius of the pulsar is:

$$\Delta R = R_\text{f} - R_\text{i} \qquad (1)$$

Apply conservation of angular momentum to the shrinking pulsar to obtain:

$$\Delta L = L_\text{f} - L_\text{i} = 0$$

or

$$I_\text{f}\omega_\text{f} - I_\text{i}\omega_\text{i} = 0$$

Substituting for I_f and I_i yields:

$$\tfrac{2}{5}MR_\text{f}^2\omega_\text{f} - \tfrac{2}{5}MR_\text{i}^2\omega_\text{i} = 0$$

Solve for ω_f to obtain:

$$\omega_f = \frac{R_i^2}{R_f^2}\omega_i$$

Because $\omega = 2\pi/T$, where T is the rotation period:

$$\frac{2\pi}{T_f} = \frac{R_i^2}{R_f^2}\frac{2\pi}{T_i} \Rightarrow R_f = \sqrt{\frac{T_f}{T_i}}R_i$$

Substitute for R_f in equation (1) and simplify to obtain:

$$\Delta R = \sqrt{\frac{T_f}{T_i}}R_i - R_i = \left(\sqrt{\frac{T_f}{T_i}} - 1\right)R_i$$

Substitute numerical values and evaluate ΔR:

$$\Delta R = \left(\sqrt{\frac{25.028\ \text{ms}}{25.032\ \text{ms}}} - 1\right)(10.0\ \text{km})$$
$$= \boxed{-79.9\ \text{cm}}$$

a 0.008% decrease in radius.

86 ••• Figure 10.60 shows a pulley in the form of a uniform disk with a rope hanging over it. The circumference of the pulley is 1.2 m and its mass is 2.2 kg. The rope is 8.0 m long and its mass is 4.8 kg. At the instant shown in the figure, the system is at rest and the difference in height of the two ends of the rope is 0.60 m. (*a*) What is the angular speed of the pulley when the difference in height between the two ends of the rope is 7.2 m? (*b*) Obtain an expression for the angular momentum of the system as a function of time while neither end of the rope is above the center of the pulley. There is no slippage between rope and pulley wheel.

Picture the Problem Let the origin of the coordinate system be at the center of the pulley with the upward direction positive. Let λ be the linear density (mass per unit length) of the rope and L_1 and L_2 the lengths of the hanging parts of the rope. We can use conservation of mechanical energy to find the angular speed of the pulley when the difference in height between the two ends of the rope is 7.2 m.

(*a*) Apply conservation of energy to relate the final kinetic energy of the system to the change in potential energy:

$$\Delta K + \Delta U = 0$$

or, because $K_i = 0$,

$$K + \Delta U = 0 \qquad (1)$$

Express the change in potential energy of the system:

$$\Delta U = U_f - U_i = -\tfrac{1}{2}L_{1f}(L_{1f}\lambda)g - \tfrac{1}{2}L_{2f}(L_{2f}\lambda)g - \left[-\tfrac{1}{2}L_{1i}(L_{1i}\lambda)g - \tfrac{1}{2}L_{2i}(L_{2i}\lambda)g\right]$$
$$= -\tfrac{1}{2}\left(L_{1f}^2 + L_{2f}^2\right)\lambda g + \tfrac{1}{2}\left(L_{1i}^2 + L_{2i}^2\right)\lambda g = -\tfrac{1}{2}\lambda g\left[\left(L_{1f}^2 + L_{2f}^2\right) - \left(L_{1i}^2 + L_{2i}^2\right)\right]$$

Because $L_1 + L_2 = 7.4$ m, $L_{2i} - L_{1i} = 0.6$ m, and $L_{2f} - L_{1f} = 7.2$ m, we obtain:

$L_{1i} = 3.4$ m, $L_{2i} = 4.0$ m, $L_{1f} = 0.1$ m, and $L_{2f} = 7.3$ m.

Substitute numerical values and evaluate ΔU:

$$\begin{aligned}\Delta U &= -\tfrac{1}{2}(0.60\,\text{kg/m})(9.81\,\text{m/s}^2)\left[(0.10\,\text{m})^2 + (7.3\,\text{m})^2 - (3.4\,\text{m})^2 - (4.0\,\text{m})^2\right] \\ &= -75.75\,\text{J}\end{aligned}$$

Express the kinetic energy of the system when the difference in height between the two ends of the rope is 7.2 m:

$$\begin{aligned}K &= \tfrac{1}{2}I_\text{p}\omega^2 + \tfrac{1}{2}Mv^2 \\ &= \tfrac{1}{2}\left(\tfrac{1}{2}M_\text{p}R^2\right)\omega^2 + \tfrac{1}{2}MR^2\omega^2 \\ &= \tfrac{1}{2}\left(\tfrac{1}{2}M_\text{p} + M\right)R^2\omega^2\end{aligned}$$

Substitute numerical values and simplify:
